The lever of the second kind has the fulcrum at one end, the strength is applied at the other, and the weight to be raised rests between them. Thus in raising the water-plug in the streets, the workman puts his iron lever through the hole of the plug till he reaches the ground on the other side, and, making that his prop, lifts the plug with his strength at the other end of the lever. In this lever also, the greater the distance of the fulcrum from the strength, the greater is the workman's power.

These instruments, as we see, assist the strength; but sometimes a workman is obliged to act at a disadvantage in raising either a piece of timber or a ladder upon one end. We cannot, with grammatical propriety, call this a *lever*, since such a piece of timber in fact in no way contributes to raise the weight. In this case, the man who is the strength or power is in the middle, the part of the beam already raised is the weight, the part yet at the ground is the fulcrum on which the beam turns or rests. Hence the man's strength will be diminished in proportion to the weight it sustains. The weight will be greater the farther it is from the fulcrum, therefore the man will bear the greater weight the nearer he is to the prop.

LEVERET, amongst sportsmen, denotes a hare in the first year of her age.

LEVIGATION, in *Pharmacy* and *Chemistry*, the reducing hard and ponderous bodies to an impalpable powder, by grinding them on a porphyry, or in a mill.

LEVITE, in a general sense, means all the descendants of Levi, amongst whom were the Jewish priests themselves, who, being descended from Aaron, were likewise of the race of Levi. In a more particular sense, *Levite* is used to signify an order of officers in that church, who were employed in performing the manual service of the temple. They were obedient to the priests in their ministration, and brought them wood, water, and other necessaries for the sacrifice. They sung and played upon instruments in the temple and in other places. They applied themselves to the study of the law, and were the ordinary judges of the country, but always subordinate to the priests. Their subsistence consisted of the tithes of corn, fruit, and cattle, throughout Israel; but the priests were entitled to a tenth of their tithes, by way of first fruits to the Lord. Forty-eight cities were assigned for the residence of the Levites, of which the priests claimed thirteen, six being chosen as cities of refuge. They were consecrated, before they entered upon their ministry, by shaving their flesh, washing their clothes, and sprinkling with the water of expiation. Imposition of hands was used in consecration, and two bullocks were offered at the door of the tabernacle. They waited weekly, and by turns, in the temple, beginning their attendance on one sabbath and ending the next, during which time they were maintained out of the offerings. In the time of Solomon, the number of Levites, from the age of twenty, and capable of serving, was thirty thousand.

LEVITICUS, a canonical book of the Old Testament, so called from its containing the laws and regulations relative to the priests, Levites, and sacrifices.

LEVROUX, a town of France, in the department of the Indre, and the arrondissement of Chateauroux. It stands on the river Nahon, and contains 330 houses, with 2900 inhabitants.

LEWES, a borough-town of the rape of Swanbrough, in the county of Sussex, situated on the right bank of the Ouse, from which it gradually rises, forty-nine miles from London. It stands at the foot of the chalk hills, and is well built and pleasantly situated. It was anciently walled, and still retains the remains of an ancient fortress. It formerly had twelve churches, now reduced to six, and before the reformation several religious houses. It has now several charity schools, and other benevolent institutions. It is not incorporated, but returns, and will continue to do so, two members to the House of Commons. The summer assizes are held here. There is some trade by the river, which is navigable for barges to Newhaven. On its banks are some cast-iron founderies. The market is held on Saturday. The population amounted in 1801 to 4909, in 1811 to 5221, in 1821 to 7083, and in 1831 to 8592.

LEWIS, one of the largest of the Hebrides, or Western Islands of Scotland, extending about eighty miles in length from north to south, and from thirteen to fourteen in breadth, consisting of a great number of isles and rocks, and parted by the sea into two divisions, called Lewis and Harris, the former lying to the westward of the latter. Lewis belongs to the county of Ross, is divided by several channels, distinguished by several names, and portioned out amongst different proprietors; but the Lewis, strictly so called, stretches out about thirty-six miles in length, from the northern point of Bowling Head to the southern extremity of Hussiness in Harris. The air is temperately cold, moist, and healthy; a great part of the low ground is flooded with lakes, and the rest is in some parts arable. Lewis is not so mountainous a region as Harris, but it is of as desert a character. Except along the margin of the sea, and in the immediate neighbourhood of Stornoway, the country is everywhere open, bare, brown, and uninteresting. The shores, particularly near the middle of the island, are deeply indented with arms of the sea, in which herrings and white fish are plentiful. A variety of streams, which issue often from small inland lakes, abound with trout and salmon. The grazing of cattle constitutes the chief means of support of the inhabitants. Lewis is divided into four parishes, viz. Barvas, Lochs, Stornoway, and Uig. There are a few scattered hamlets, but only one

Lewis.

town, Stornoway, which lies on the east side of the island, at the head of a bay or harbour, to which it gives its name. It is a place of considerable size, and there are in it schoolmasters and missionaries for the instruction of the inhabitants. It is a singular fact, that the latter are of unmixed Danish origin, which is the case in none of the other islands. The population amounts to about 12,000.

Lewis is the name of an instrument which is indented into a large stone, and has a ring for the purpose of making fast a rope, in order to move the stone, or to act as a stay. It is called in Italian *ulivella*, in French *la louve*, in German *stein zange*. The lewis consists of three wedges of iron, forming, when put together, a dove-tail. The wedges are inserted into an equal and similar hollow dove-tail excavated in the stone. This hollow dove-tail is made exactly of the form and size of the lewis, and is a figure of six sides; a pair of vertical sides, which are opposite, equal, and parallel, and in form of truncated isosceles triangles; a pair of inclined sides, opposite equal rectangles, equally inclined to the axis of the hole, and not parallel. The top and base of the hole are rectangles parallel to each other, the base being longer than the top. The centre of the base and the centre of the top are in one vertical line. The form of the hole therefore is that of an inverted wedge with the point cut off; it is like a cavity fitted to contain the inverted keystone of an arch. When the iron dove-tail called the lewis is inserted into this hollow dove-tail made in the stone, the ring at the smaller and upper end of the iron dove-tail serves for making fast a rope, for the purpose of raising the stone. The constitution of the substance of timber enables the workman to fix a rope to it by merely inserting a screw or a spike into the log; stone will not admit of these, and is made fast by the contrivance of the lewis. The lewis of the most useful form, and that which is used in Britain, is represented at fig. A, Plate CCCXXI.; *a* and *b* are two pieces of iron, in form of inverted wedges. These pieces are inserted into a quadrangular hole which is made in the stone. The two opposite and shortest sides of the hole are dove-tailed, or, in other words, under-cut, as represented at fig. B, which is a vertical section of the hole; *t* is the plan of the hole at top, *o* is the plan of the bottom of the hole. The hole, as represented in the figure, is five inches long at top, and six inches at bottom; the width is one inch; the depth seven inches. Sometimes the width is one and a half inch, and the depth four or five inches. The hole is made of such a size that the lewis fits exactly into it; *a′*, *c′*, *b′*, are transverse geometrical views of the pieces *a*, *c*, *b*; in the transverse views it is seen that the transverse sections of the parts of these pieces that enter the stone are of the same breadth from top to bottom. The piece *c* is represented with a perforation at top, for the purpose of taking out this piece more easily when the lewis is to be unshipped, but the lewis is usually made without this upper perforation. The pieces *a*, *b*, are first introduced into the hole, then is driven in *c*, which may either be a parallelopiped, or it may be a little thicker above, in form of a wedge; the ring *m* is then put on, and the bolt *g h* is passed through the holes of the ring and of the three pieces; the bolt enters at *g*, and forelocks at *h*. The tackle by which the stone is to be elevated is hooked on the ring *m*. This ring, in cases where a rope is to be passed through it, is bound round with cord, to prevent the rope from being chafed by the iron of the ring.

Piranesi has proposed and figured some other forms of this machine in his *Antichità di Roma*, but they do not appear to be so convenient as the lewis of the common form above described: one of the forms of lewis given by Piranesi is represented at fig. F. The two pieces which constitute the iron dove-tail open and shut by a joint; *n* is a bolt, which is put into the round hole at *p* after the instrument is inserted into the stone; this transverse bolt serves to keep the legs of the instrument spread out, so as to retain the form of the dove-tail. The lewis of the most usual form, represented at fig. A, and a lewis of another form, fig. G, are figured and described in Perrault's *Vitruvius*, lib. x. chap. 2, and in the *Theatrum Machinarum*, tab. xxxv. p. 111. In the lewis, fig. G, the iron dove-tail L has a ring at top, *r*, for receiving a rope; L is put into the dove-tailed hole in the stone, and then the two parallelopipedal iron bolts *e*, *u*, are put in on each side of the iron dove-tail; *e* and *u* are of equal thickness throughout. The top of the hole must not be less than the bottom of the piece L, to the end that L may enter into the hole. The ring must not project beyond the lines which form the prolongation of the inclined sides of the wedge L; for if the ring projected, the pieces *e*, *u*, could not be put into the hole. The hole must be formed so that the machine may fit accurately into it.

The lewis is used for raising large stones of several tons weight, in the building of harbours, bridges, and other solid fabrics, which, from the forces by which they are assailed, or on account of the long period they are designed to endure, require to be constructed of great masses of stone. Leupold, in his *Theatrum Machinarum*, mentions, that in many churches in Holland the pavement consists of large slabs of stone or marble, each of them the size of a grave, and covering a burying-place; these slabs are laid close to one another, and join accurately, so that no lever or crow can be introduced into the joint to raise them; in each of the slabs there is a hole cut in form of a hollow dove-tail, and into this hole a lewis is introduced when occasion requires that the tomb should be opened.

In the construction of harbours, the lewis fixed in a large stone frequently serves to make fast the ropes which stay the cranes. The lewis is commonly used in the docks at London for fixing mooring-rings in the stone: the ring is easily removed when requisite, by unshipping the bolt of the lewis; for this and other reasons it is found more convenient to employ the lewis for fixing rings, than to run the ring-bolt into the stone with melted lead.

The largest stones that have been wrought and moved by the industry of man, occur in the buildings of the ancient Egyptians; but it is not ascertained whether their architects employed the lewis.

Piranesi, in his *Antichità di Roma*, describes and figures lewis-holes existing in the upper surface of the large stones of the tomb of Cæcilia Metella, at Capo di Bove, near Rome. The *forcipes ferrei quorum dentes in saxa forata accommodantur*, mentioned by Vitruvius (lib. x. cap. 2), denote a machine in the form of nippers, used to effect the raising of stones in the same way as the lewis; but the words seem to indicate a machine different in form from the lewis. Piranesi also observed in some ancient unfinished buildings, stones which appeared to have been raised by another method, namely, by knobs left on the front and side of the stone, to which knobs the ropes were attached. The knobs were taken off when the building was finished.

Vasari relates, in his account of Brunalesco, that the use of the lewis was revived in Italy by that architect, who was well skilled in mechanics, and who constructed the cupola of the cathedral church of Santa Maria del Fiore, at Florence, about the year 1430; the first great cupola that was built in Europe, and which Michel Angelo had in view when he designed the cupola of St Peter's. The lewis called Brunalesco's is represented at fig. C, Plate CCCXXI. Leo Baptista Alberti, a Florentine architect, who lived in 1440, in his treatise *de Architectura*, mentions the lewis by the Latin name of *impleola*. He describes the side wedges as having the figure of the letter

D, and from that form the machine had its Italian name *ulivella*, that is to say, *little olive*. Philander of Chatillon, in his *Commentary on Vitruvius*, published at Rome in 1544, gives a figure of the lewis used at Rome in his time, which resembles that used in England, and represented at figure A. In the *Archæologiæ* (vol. x.) there is a description of holes observed in the keystones of the Abbey Church of Whitby, which was built about 1370, in the reign of Edward III. as is supposed. These holes appear to have been lewis-holes; they are of the form of an inverted Y, as represented at fig. D, where *w* is the plan of the top of the hole, and *t t* the plan of the bottom; the lewis that fitted into these holes would resemble that represented at fig. E. These keystones at Whitby weigh about one ton and a half.

LEWIS, or *Louis*, the name of several kings of France. See the article FRANCE.

LEWISHAM, a parish in the hundred of Blackheath and county of Kent, six miles from London, situated on a branch of the river Broxbourne. It is chiefly inhabited by the richer class of citizens of the metropolis as their country retreats. The church is an elegant modern structure, rebuilt since it was destroyed by a fire. The population amounted in 1801 to 4007, in 1811 to 6625, in 1821 to 8185, and in 1831 to 9659.

LEXIARCHI, at Athens, six officers, assisted by thirty inferior ones, whose business it was to impose fines upon such as came not to the public assemblies, and also to make scrutinies amongst such as were present. The lexiarchi kept a register of the age, manners, and abilities of the citizens, who were always enrolled at the age of twenty.

LEXICON, the same with dictionary. The word is chiefly used in speaking of Greek dictionaries, and is derived from the Greek λεξις, *word, diction*, from λεγω, *I speak*.

LEXINGTON, a town of Kentucky. See KENTUCKY.

LEYDEN, a circle of Holland, divided into three cantons, viz. Leyden, Noordwyk, and Woubrugge, and containing about 60,000 inhabitants. The city of Leyden, which gives its name to the circle, is situated on both sides of a branch of the river Rhine, which, though diminished by other branches that take their course to the sea before it arrives at this city, still retains its original name. It receives here the water of the smaller streams of the Does, the Bliet, the Mare, and the Zyl, and is, besides, intersected by several canals, thus dividing the city into numerous islands, which are connected together by nearly 100 bridges. The streets are broad, clean, and well paved; and the high street, which runs through the whole city, is perhaps one of the finest in Europe. The walks in and around the city are distinguished by their pleasing neatness. The most striking building is the stadthouse, in which is the fine picture of the last judgment by Lucas. St Peter's church is remarkable for the sarcophagus to the memory of Boerhaave, and monuments to three of the most distinguished citizens who lost their lives by the explosion of a vessel laden with gunpowder in 1807. There are, besides, sixteen other churches, and two fine hospitals, one of the finest of which is that which belonged to the Catholics a few years ago. The university, founded in 1575, has long maintained a high rank amongst the best institutions for education in Europe, and has produced the most distinguished men in every branch of knowledge. It now contains about twenty professors in the four departments of law, theology, medicine, and philosophy, and from 300 to 400 students. Attached to the university is a library, containing 60,000 volumes of books, and 14,000 manuscripts, some of them of the most valuable and curious kinds. It has also an observatory, an anatomical theatre, a botanic garden, a chemical laboratory, and several collections of natural and physical curiosities. The trade and manufactures of Leyden were once very extensive, but have much declined of late years. It has still, however, some considerable manufactures of woollen and linen cloths, and the black and scarlet cloths are much admired for their beautiful and permanent colours. The printing of books, especially of classical books, was once a great branch of industry, though now it is much diminished. Leyden has been the birth-place or residence of some of the most distinguished individuals, especially of Rembrandt and Lucas, painters; of Muschenbroeck and Boerhaave, naturalists; and of Scaliger, Salmasius, Heinsius, and others, critical and classical scholars. In 1816, the population was 28,600, but since that time it has increased, and, by the census of 1830, appears to be 34,564, viz. 16,131 males, and 18,433 females. It is situated in latitude 52. 8. 25. north, and longitude 4. 22. east. The environs of the city are ornamented with many seats of the inhabitants. The soil is rich, but, from its moisture, more appropriate for pasture than for grain. The dairies are numerous, and afford butter excellent for its flavour; and, from being capable of being kept a long time, it, along with cheese, forms an important part of the exportable commodities of Holland.

Leyden.

LEYDEN *Isle*, an island situated off the north-west coast of Ceylon, about thirteen miles in length by two and a half in breadth. It contains excellent pasture for cattle and horses.

LEYDEN, *John*, a celebrated linguist, antiquary, and poet, was born on the 8th of September 1775, at Denholm, a village on the banks of the Teviot, nearly opposite to Minto House, in the parish of Cavers and county of Roxburgh. His father was able to trace back his pedigree through a line of shepherds and husbandmen who had long occupied small farms on the estate of Douglas of Cavers, one of whom, Adam Ledan, in Little Cavers, a stern Presbyterian, had been denounced as a rebel, in a royal proclamation, in 1684. From his second to his sixteenth year, young Leyden lived with his parents in a retired cottage near the bottom of the "stormy Ruberslaw," where he was taught to read by his father's mother, and where he had no companions except the inmates of that rustic dwelling, and no books except the Bible, and such other volumes as are commonly possessed by the Scottish peasantry. His chief delight in the years of childhood was to listen to the tales of martial adventure and supernatural agency, recited by a blind uncle of his mother, and to read such works as the Metrical Histories of Bruce and Wallace, the Poems of Sir David Lindsay, and the *Arabian Nights' Entertainments*. In his tenth year, he went first to school at Kirktown, a distance of two miles from his father's house, and there, under three successive schoolmasters, he learned writing, arithmetic, and the elements of Latin grammar. After having spent three years in this manner, he was placed under the charge of Mr Duncan, a Cameronian minister at Denholm; and at the end of two years, not unprofitably employed in this small seminary, he entered the university of Edinburgh in November 1790. Mr Dalzel, then professor of Greek, has repeatedly stated to the writer of this article, that he had seldom known any young man who at first appeared worse prepared for college, and who so speedily surmounted the disadvantages of imperfect tuition. He had accumulated a great stock of knowledge by a process of study peculiar to himself; but he had not thought it necessary to make himself master of grammatical rules; and, with all his strength and acuteness of mind, he at this time expressed his meaning in terms exceedingly awkward, and in a tone of voice so dissonant and loud as to set his fellow-students in a roar. He attended three winter sessions at the classes for languages and philosophy, applying with extraordinary ardour to every branch of inquiry connected with his academical studies, and to many other pursuits in which none of his instructors could have guided him. The vacations were generally passed in his native wilds amongst his own relations, with the exception of the summer 1792, when he acted as assistant in a village school at Whitebanklee, or Clovenfords, on Cadon Water, a mountain stream which falls into the Tweed below Ashiesteel, on the skirts of Ettrick Forest. The charge of the school was left almost entirely to him; but the management of thirty boys and girls, from six to twelve years of age, appeared to be a task for which he possessed no manner of aptitude. Two of his pupils, who were learning Latin, looked up to him with deference and admiration; one of whom did not long survive him, and the other has held various appointments in the church and the universities; but the children in general were in a state of insubordination and tumult, which he endured with a degree of calmness, of which those who knew him in maturer life would have conceived him to be incapable. At this time his appearance was very prepossessing. He was ruddy and fair, with a frame rather delicate than robust, and an expression of great good-nature and gentleness in his features.

In November 1793, he entered on the study of divinity, church history, and Hebrew, and passed through the usual course of four years' attendance, before he was proposed for trials as a licentiate or probationer of the church of Scotland. Much of his attention was in the mean time devoted to historical research, to philology, to metaphysical speculations, and to natural history and medicine. He was a member of various debating societies, in all of which he distinguished himself by the fluency and copiousness of his unpremeditated harangues, rather than by any graceful or polished eloquence. In one of these institutions, he contracted an intimacy with Mr Henry Brougham, and with the late Dr Thomas Brown and Mr Francis Horner, as well as with several other individuals, who subsequently attained no inconsiderable distinction. About the same time he formed an acquaintance with some literary men farther advanced in life, as Mr Thomson, author of *Whist*, a poem, and Dr Robert Anderson, editor of the British Poets, and then supposed to be connected with the *Edinburgh Magazine*, to which both Leyden and Mr Thomas Campbell, one of his youthful friends, contributed some of their earliest poetical essays.

When he had completed his theological education, he accompanied one or two pupils to St Andrews in 1797, where he eagerly embraced the opportunity of attending the lectures of Dr Hunter, professor of humanity, and of Principal Hill, one of the divinity professors. He became also a member of the Theological Society, in which he delivered a number of discourses, one *On the Argument a priori for the Existence of God*; another *On Thanksgiving*; and two *On Regeneration.* He also engaged at almost every meeting in the discussion of some controverted point in divinity or philosophy; and it cannot be doubted that these discussions must often have been highly interesting, when such persons engaged in them as Dr Chalmers, whose speeches differed from most of the others in being generally read. Amongst the members at that period were, Mr Duncan, now professor of mathematics at St Andrews, and Sir John Campbell, now attorney-general of England. In one respect Leyden felt and acknowledged his inferiority to the students at St Andrews, namely, in having paid scarcely any attention to mathematics; a study for which he had so little turn, that, by his own account, he could never comprehend the definition of a straight line, owing to some metaphysical difficulty, which nobody could solve to his satisfaction. He appears to have disliked the style of society in St Andrews, where, however, he acquired more than one of his most valued friends, particularly Dr Hunter, and another gentleman of high intellectual capacity and scientific attainments. From the presbytery of St Andrews he received license to preach, in May 1798; and on this occasion he was much disgusted by a vulgar piece of waggery, attempted to be practised, at his expense, by one of the members, who told him, that, as he would be called upon to return thanks after dinner, it was expected that, according to established custom, he should give a specimen of his gifts in prayer, by using a form of words comprehending all the leading doctrines of the Christian faith. When the expected signal was given, Leyden stood up and began to pronounce such a prayer as might have been very suitable for the church; but after having proceeded at some length, and in a very sonorous voice, to enumerate the Divine attributes, he perceived that the company was astonished by this unusual exhibition, and sitting down abruptly in no very placid humour, he was more than half disposed to inflict personal chastisement on the offending individual, with whom he felt enraged, not merely on account of the indignity offered to himself, but for the indecent mockery of one of the solemnities of religion. About this time he returned to Edinburgh, where he frequently preached, not indeed so as to attract popular admiration, but in a manner which satisfied his numerous friends that he possessed a serious, as well as a philosophical mind. His memory was retentive; but, in conducting the devotions of a religious assembly, he was apt to be disconcerted by circumstances which would have given him no uneasiness if he had been addressing a learned society.

In the winter of 1798, he attended some of the medical classes, and at this period nearly lost his life, in consequence of his rash and unskilful treatment of a complaint which he believed to be an attack of colic. He swallowed a glass of spirits, in the expectation of receiving immediate relief; but the disorder proved to be *enteritis*, or inflammation of the intestines, and his constitution was so much weakened by venesection, blistering, and evacuations, that he never afterwards recovered the bloom of health. In addition to his duties as a tutor in a family, by which much of his time was engrossed, he had been engaged as a writer in the *New London Review*, and, amongst other articles, contributed those on Horne Tooke's *Diversions of Purley*, on Dr Thomas Brown's *Observations on Zoonomia*, and on Vallancey's *Sanscrit History of Ireland.*

In the summer of 1799, he published a volume, entitled *A Historical and Philosophical Sketch of the Discoveries and Settlements of the Europeans in Northern and Western Africa, at the Close of the Eighteenth Century.* This interesting piece (an octavo of 442 pages) was written in about six weeks, whilst the author was in bad health, and at a distance from books; but it exhibits proofs of extensive information, as well as of sound reflection. In the course of the autumn he engaged to publish *The Complaynt of Scotland*, a very rare anonymous work in the Scottish language, written early in the sixteenth century. It did not appear for nearly two years; but the preliminary dissertation, extending to nearly 300 pages, as well as the notes and glossary, indicated a compass of antiquarian lore, and a depth of research in various other unfrequented walks of erudition, which could not easily be rivalled. He also displayed great acuteness and ingenuity in attempting to prove, from internal evidence, that *The Complaynt* was the production of Sir David Lindsay.

Through Mr Richard Heber, to whom he was introduced by Mr Constable, he became acquainted with the most distinguished literary characters in Edinburgh, and, amongst others, with Sir Walter Scott, who at this time was engaged in collecting the ancient traditionary rhymes published in the *Minstrelsy of the Scottish Border;* a collection which Leyden contributed largely to enrich, both by recovering unedited fragments of antiquity, and by communicating imitations, written in the spirit and manner of the age of chivalry, as well as by furnishing materials for many of the notes, and particularly for the introduction to the tale of *Tamlane*, containing a learned dissertation on the Fairies of popular superstition.

In the year 1800, a plan was formed to establish him as assistant and successor to the minister of his native parish'; but it failed, in consequence of the reluctance of the incumbent to agree to an arrangement on which the heritors and parishioners had set their hearts. Soon afterwards, he was anxious to obtain the professorship of rhetoric and belles lettres in Edinburgh; but here also he was doomed to experience a disappointment.

About this time he made two successive tours through the Highlands, and collected much curious information, which was once intended for publication. He wrote several poems, founded on the remains of Celtic story, two of which have been inserted in the *Border Minstrelsy*. In 1801, he also contributed to Lewis's *Tales of Wonder.*

The year 1802, the last which he spent in Scotland, was one of the busiest of his life. About the beginning of the year, he had carried through the press nearly half a volume of an enlarged *Account of the Progress of Discovery in Africa.* At the same time he engaged to conduct the *Scots Magazine*, on an improved plan; and the volume for that year contains many articles furnished by him, and by another eminent orientalist, the late Dr Alexander Murray. He was also employed in correcting the papers of the Highland Society for publication; and he edited a volume entitled *Scottish Descriptive Poems, with some Illustrations of Scottish Literary Antiquities*, containing *Clyde*, by John Wilson, schoolmaster of Greenock; *Albania*, addressed to the Genius of Scotland; *The Day Estival*, by Alexander Hume; and *Poems*, by William Fowler. Early in this year, he offered to the African Society to explore the interior of those obscure and inhospitable regions in which so many Europeans have perished. His friends, alarmed at this apparently fatal resolution, became eager to obtain for him an Indian appointment, that might give him access to the treasures of eastern learning, which his past attainments peculiarly qualified him to appreciate. Through the interest of Mr William Dundas, he was nominated assistant surgeon; and though it was privately stipulated, that, on his arrival in India, he was to devote himself chiefly to literary inquiries, he could not be permitted to go out as a passenger in that capacity, without producing a surgeon's diploma, and undergoing an examination before the Medical Board. He had attended many of the medical classes, but he had hitherto paid little attention to the practice of surgery, and it was therefore necessary to prepare himself for passing through the strict trials prescribed by the college of surgeons. It reflects no slight credit on his capacity and application, that he accomplished this task within six months. He was not equally successful in procuring the degree of doctor of physic from the university of Edinburgh; but having gone to St Andrews with certificates of his character and regular education, and having satisfied the Senatus Academicus at a private examination, as well as by reading several exercises prescribed to him in the Latin language, that degree was conferred on him there, on the 7th of August 1802. Whilst he was occupied in these unpoetical avocations, he continued at every interval of leisure to court the inspiration of the muses, and he gave the finishing hand to the *Scenes of Infancy, descriptive of Teviotdale*, a poem which had been partly written before, but which was now enlivened by some of its most touching passages, and left for publication in the hands of Dr Thomas Brown, who, in the revision of the sheets, suppressed a number of verses which the author conceived ought to have been retained.

Leyden spent the winter in London, having narrowly escaped the misfortune of sailing in the Hindostan, which was wrecked in its passage down the Thames. He sailed from Portsmouth in the Hugh Inglis, on the 7th of April 1803, and soon after his arrival at Madras, was attached as surgeon and naturalist to the commission for surveying the districts of the Mysore, in which capacity he was expected to turn his attention, not only to the natural history of the country, but to the manners, institutions, and language of the inhabitants. His constitution had nearly sunk under the labours to which he subjected himself, and he was under the necessity of removing to Prince of Wales's Island. Here he was befriended by the governor, Mr Dundas, and here too he procured the chief materials of the *Essay on the Languages and Literature of the Indo-Chinese Nations*, contained in the tenth volume of the *Asiatic Researches.*

He removed in 1806 from Prince of Wales's Island to Calcutta, where, through the favour of the governor-general, Lord Minto, he was appointed one of the professors in the Bengal College, from which station he was soon transferred to the office of judge of the Twenty-four Pergunnahs of Calcutta. The income attached to this charge was applied chiefly in purchasing manuscripts, and rewarding the native teachers whose instructions he solicited; and all his leisure hours were spent in the eager investigation of the languages, the laws, and history of the East. In 1809 he was appointed a commissioner of the court of requests in Calcutta, and, in the end of the following year, having resigned this office, he obtained the office of assay-master of the mint. Soon afterwards, he was required to attend Lord Minto upon the expedition to Java, that he might be employed in collecting information with respect to the learning and institutions of the native tribes, and that the governor-general might enjoy the benefit of his services in negotiating with the local authorities, and in adjusting the future government of the country. After the British troops took possession of the city of Batavia, he ventured rashly into an ill-aired library, supposed to contain many Indian manuscripts, and, on leaving it, was immediately seized with a fever, which proved fatal three days after its accession, and a few days before the conquest of the island was completed. He died on the 21st of August 1811.

A very high tribute to his memory was paid by Lord Minto, on occasion of a visitation of the College of Fort-William, after his lordship's return from the conquest of Java. "To speak of all that Dr Leyden had already performed, especially in the prosecution of Asiatic learning—to compute the treasures which his incomparable genius, urging and sustaining his invincible powers of mental labour, presented the fair promise of acquiring and accumulating—would be to relate a history of the short but memorable life he was allowed to live, and to expatiate into the yet more ample fields of inquiry of which he had projected the survey. I need not remind those who hear me, of the zeal he had long nourished for exploring the philology of the more eastern regions of Asia; of the first steps he had already made in the prosecution of that purpose, by the construction of vocabularies, but, above all, by methodising and reducing into system the classification of the various languages spoken on the continent intermediate between India and China; the various kingdoms and districts of which, as they recede from each of these extreme points, appear, with some relation to their local approximation, or to historical affinities, gradually to have blended and assimilated their respective languages into compound dialects, partaking of both the distinct and primitive tongues. To this just and authorized tribute to the literary merits of Dr Leyden, I must yet add a personal testimony, prompted by personal experience, to virtues of a higher class, neither connected with the talents and toils of a student, nor so uniformly the companions of learned reputation, as it would be natural perhaps to wish and to expect. But I speak it in the presence of many who can attest it with myself, that, founder as he was of his own fortunes and reputation, and climbing, by many laborious steps, from the lowest stage of social life, to an eminence which many cannot even maintain, though placed yet higher by their birth; no man, whatever his condition might be, ever possessed a mind so entirely exempt from every sordid passion, so negligent of fortune and all its grovelling pursuits, in a word, so entirely disinterested, nor ever owned a spirit more firmly and nobly independent. I speak of these things with some knowledge, and wish to record a competent testimony to the facts, that, within my experience, Dr Leyden never, in any instance, solicited an object of personal interest, nor, as I believe, ever interrupted his higher pursuits, to waste a moment's thought on those minor cares. To this exemption from cupidity was allied every generous virtue worthy of those smiles of fortune which he disdained to court; and amongst many estimable features of his character, an ardent love of justice, and a vehement abhorrence of oppression, were not less prominent than the other higher qualities I have already described."

Sir John Malcolm bears testimony, in terms equally strong, to the purity, disinterestedness, and independence of his character, as well as to the indefatigable perseverance and ardour with which he devoted himself to literary and scientific acquirements; and, after adverting to some rather unpleasing oddities of manner, "How trivial," he adds, "do these appear, at a moment when we are lamenting the loss of such a rare combination of virtues, learning, and genius, as were concentrated in the late Dr Leyden."

(See *Edinburgh Annual Register for* 1811; and *The Poetical Remains of the late Dr John Leyden, with Memoirs of his Life*, by the Rev. James Morton, 8vo, London, 1819.) (P. P. P.)

LEYRIA, a city of Portugal, in the province of Estremadura. It is situated on the banks of the river Lis, at its confluence with a smaller stream, and was formerly a royal residence, well fortified. Its inhabitants are now estimated to amount to 4000. It is the see of a bishop, and contains a cathedral, two parish churches, an hospital, an almshouse, and 630 houses.

LEYTA, one of the southernmost of the Philippines, ninety-five miles in length by thirty-eight in breadth. The soil is fertile, and the mountains abound in deer, wild hogs, and fowls. The air is pure, healthy, and temperate. A chain of mountains runs through the island in a direction north-west and south-east; and so materially do they influence the climate, that the seasons are entirely different on opposite sides of the mountains. The inhabitants amount to 9000, who pay a tribute in wax, rice, or cloth. Long. 124. 40. E. Lat. 10. 50. N.

LEYTON, Low, a village in the hundred of Becontree, in the county of Essex, six miles from London, on the border of Epping Forest. It is chiefly filled with houses used as country-seats by the richer traders of the metropolis, and is supposed to have been a Roman station under the name of Durolitum. The population amounted in 1801 to 2519, in 1811 to 3162, in 1821 to 3374, and in 1831 to 3223.

LEZOUX, a city of France, in the department of the Puy-de-Dome, and arrondissement of Rioum, containing an hospital, 570 houses, and 3450 inhabitants.

LHUYD, or Lhoyd, *Humphrey*, a learned antiquary of the sixteenth century, born at Denbigh. He applied himself to the study of physic, and, living mostly within the walls of Denbigh Castle, practised there as a physician, and died in 1570, with the character of a well-bred gentleman. He wrote and translated several pieces relative to history and antiquities, particularly the History of Cambria, or Wales, from Caradoc of Langcarvan, which, however, he did not live to finish; but Sir Henry Sidney, lord-president of Wales, employed Dr David Powel to complete it, and by him it was published in 1584. A new and improved edition of this work was published in 1774.

Lhuyd, *Edward*, keeper of the museum at Oxford, was a native of South Wales, and the son of Mr Charles Lhuyd of Lhanvorde. He was educated at Jesus College, Oxford, where he was created master of arts in July 1701. He was bred under Dr Plot, whom he succeeded as keeper of the Ashmolean Museum, and had the use of all Vaughan's collection. With incessant labour and great exactness he employed a considerable part of his life in searching into the Welsh antiquities, and perused or collected a great deal of ancient and valuable matter from their manuscripts; transcribed all the old charters of the monasteries that he could meet with; travelled several times over Wales, Cornwall, Scotland, Ireland, and Armorica (Bretagne), countries inhabited by the same people; compared their antiquities, and made observations on the whole. But he died in July 1709, before he had digested them into the form of a treatise, as he intended, on the ancient inhabitants of this island. The untimely death of this excellent antiquary prevented the completion of many admirable designs. For want of proper encouragement, he did very little towards illustrating the British bards, having seen but one of those of the sixth century, and not being able to procure access to two of the principal libraries in the country. He communicated many observations to Bishop Gibson, whose edition of the *Britannia* he revised; and he published *Archæologia Britannica*, giving some further account of the language, history, and customs of the original inhabitants of Great Britain, from collections and observations made in travels through Wales, Cornwall, Bretagne, Ireland, and Scotland. He left in manuscript a Scottish or Irish-English Dictionary, proposed to be published in 1732 by subscription, by Mr David Malcolm, a minister of the church of Scotland, with additions; as also the Elements of the same Language, with necessary and useful information, for propagating more effectually the English language, and for promoting the knowledge of the ancient Scottish or Irish, besides many branches of useful and curious learning. Lhuyd, at the end of his preface to the *Archæologia*, promises an historical dictionary of British persons and places mentioned in ancient records; and it seems to have been ready for press, though he could not fix the time of publication. His collections for a second volume, which was to give an account of the antiquities, monuments, and remains, in the principality of Wales, were numerous and well chosen; but, on account of a quarrel between him and Dr Wynne, then fellow, and afterwards principal, of the college, and bishop of St Asaph, he refused to buy them, and they were purchased by Sir Thomas Sebright of Beachwood, in Hertfordshire. They consist of about forty volumes in folio, ten in quarto, and above a hundred of smaller size, all relating to Irish or Welsh antiquities, and chiefly in those languages. Carte made extracts from them about 1736; but these were chiefly historical. Sir John Sebright gave to Mr Pennant twenty-three of Lhuyd's manuscripts, in Latin and English. Many of his letters to Lister, and other learned contemporaries, were presented by Dr Fothergill to the University of Oxford, and are now in the Ashmolean Museum. Lhuyd undertook art more for illustrating the Celtic part of the kingdom than any man besides ever attempted.

LIANCOURT, a town of the arrondissement of Clermont, in the department of the Oise. It is situated on the river Bresche, and contains about 1200 inhabitants; and it is remarkable for the castle and park of the duke of the same name. It is celebrated for its manufactures of cambrics, lenos, lawns, and cotton goods of the finer kinds.

LIBANIUS, a Greek rhetorician and sophist in the fourth century, was born at Antioch, and shared the friendship of Julian the Apostate. That prince offered him the dignity of *prœfectus prœtorio;* but Libanius refused it, thinking the name of sophist, or professor of eloquence, much more honourable. There are still extant several of his letters and Greek orations, by which he acquired great reputation; but his style is somewhat affected and obscure. St Basil and St Chrysostom were his disciples about the year 360. His letters were published at Amsterdam in 1738, and his Orations at Venice in the year 1755. Libanius was a pagan.

LIBANOMANTIA, in *Antiquity*, a species of divination, performed with frankincense, which, if it presently caught fire, and sent forth a grateful odour, was esteemed a happy omen, and *vice versâ*.

LIBANUS, a lofty mountain of Syria, the ancient Lebanon, so celebrated in Scripture. Its direction is nearly north and south, from the vicinity of Tripoli to the borders of Palestine. Its distance from the Mediterranean is from thirty to forty miles. To the east there is the parallel chain of Anti-Libanus, which is covered with snow at its summit. The exact height of the mountain of Lebanon has not been ascertained. Mr Buckingham ascended to its summit; but he does not state its precise height, which must be considerable, as it is covered with snow to an unknown depth at all seasons; for he mentions, that though his horses sometimes sunk to the belly, they never were able to penetrate to the ground. The cedars of Lebanon, so often mentioned, still flourish at a lower level on the hill. Mr Buckingham saw about 200 cedar trees, all fresh and green. Some of them were very large, the trunk ten or twelve feet in diameter, with branches of corresponding size, each of them like large trees extending outward from the parent stock, and overshadowing a large space of ground. The view from the summit was magnificent, embracing the boundless prospect of the ocean to the westward, with the coasts of Syria. To the east the prospect was interrupted by the range of Anti-Libanus. The mountain consists of a species of limestone, which presents frequently the appearance of towers and castles.

LIBATION, amongst the Greeks and Romans, was an essential part of solemn sacrifices. It was also performed alone, as a drink-offering, by way of procuring the protection and favour of the gods in the ordinary affairs of life. Libations, according to the nature of the gods in honour of whom they were made, consisted of different liquids, but wine was that most usually employed. The wine offered to the gods was always unmixed with water. There were libations of water, libations of honey, libations of milk, and libations of oil, called *νηφαλια ἱερα*. The libation was made with a serious deportment and solemn prayer. At sacrifices, the libation, after it had been tasted by the priest, and handed to the bystanders, was poured out upon the victim. At entertainments a little wine was generally poured out of the cup, before the liquor began to circulate, to show the gratitude of the guests to the gods for the blessings they enjoyed.

Libations were likewise in use amongst the Hebrews, who poured out a kind of wine on the victim after it was killed; and the several pieces of the sacrifice were laid upon the altar, ready to be consumed in the flames.

LIBEL (*libellus famosus*), taken in its largest and most extensive sense, signifies any writing, picture, or the like, of an immoral or illegal tendency; but, in a peculiar sense, it denotes a malicious defamation of any person, and especially of a magistrate, made public either by printing or by writing, by signs or by pictures, in order to provoke him to wrath, or expose him to public hatred, contempt, and ridicule. The direct tendency of these libels is a breach of the public peace, by stirring up the objects of them to revenge, and perhaps to bloodshed. The communication of a libel to any one person is a publication in the eye of the law, and therefore the sending an abusive private letter to a man is as much a libel as if it were openly printed, for it equally tends to provoke a breach of the peace.

With regard to libels in general, there are two remedies; one by indictment, and another by action. For the public offence, the remedy is indictment; because every libel has a tendency to break the peace, or provoke others to break it, an offence which is the same whether the matter contained be true or false; and therefore the defendant, on an indictment for publishing a libel, is not allowed to allege the truth thereof by way of justification. But in the remedy by action on the case, which is to repair the party in damages for the injury done him, the defendant may, as for words spoken, justify the truth of the facts, and show that the plaintiff has received no injury at all. What has been said with regard to words spoken, will also hold in every particular with regard to libels by writing or printing, and the civil actions consequent thereon; but as to signs or pictures, it seems necessary always to show, by proper inuendos and averments of the defendant's meaning, the import and application of the scandal, and that some special damage has followed; otherwise it cannot appear that such libel by picture is understood to have been levelled at the plaintiff, or that it was attended with any actionable consequences.

In a civil action, then, a libel must appear to be false as well as scandalous; for, if the charge be true, the plaintiff has received no private injury, and has no ground to demand a compensation for himself, whatever offence it may be against the public peace; and therefore, upon a civil action, the truth of the accusation may be pleaded in bar of the suit. But, in a criminal prosecution, the tendency which all libels have to create animosities, and to disturb the public peace, is the sole consideration of the law. Hence, in such prosecutions, the only points to be considered are, first, the making or publishing of the book or writing; and, secondly, whether the matter be criminal; and, if both these points are against the defendant, the offence against the public is complete. The punishment of such libellers, for concocting, repeating, printing, or publishing the libel, is a fine, and such corporal punishment as the court in its discretion may inflict; regard being had to the quantity of the offence, and the quality of the offender. By the law of the Twelve Tables at Rome, libels which affected the reputation of an individual were made a capital offence; but before the reign of Augustus, the punishment became corporal only. Under the Emperor Valentinian it was again made capital, not only to write, but to publish, or even to omit destroying libels. In this and many other respects, our law corresponds rather with the middle age of Roman jurisprudence, when liberty, learning, and humanity, were in their full vigour, than with the cruel edicts that were established in the tyrannical age of the ancient decemviri, or in that of the latter emperors.

LIBELLA, a piece of money amongst the Romans, being the tenth part of the denarius, and equal in value to the *as*. It was called *libella*, as being a little pound, because equal to a pound of brass.

LIBELLI, the name given to the bills which were put up amongst the Romans, giving public notice of the time when a show of gladiators would be exhibited, with the number of the combatants, and other circumstances. This was called *munus pronunciare* or *proponere*. The *libelli* or bills were sometimes termed *edicta*. These public notices were given by the person who intended to oblige the people with a show, and were frequently attended with pictures representing the engagement of some celebrated gladiators. There was also the *famosus libellus*, or defamatory libel. Seneca calls them *contumeliosi libelli*, infamous rhymes, which, by a Roman ordinance, were punishable with death. *Libellus* in the civil law also signifies the declaration, or state of the prosecutor's charge against the defendant; and it has the same signification in the English spiritual courts.

LIBERA, in *Mythology*, the name of a goddess, which Cicero, in his book *De Natura Deorum*, represents as the daughter of Jupiter and Ceres. Ovid, in his *Fasti*, says, that the name was given by Bacchus to Ariadne. Libera is exhibited on medals as a kind of female Bacchus, crowned with vine leaves.

LIBERAL ARTS, are such as depend more on the labour of the mind than on that of the body; or, which consist more in speculation than operation, and have a greater regard to enlightened amusement and curiosity than to necessity. The word comes from the Latin *liberalis*, which amongst the Romans signified a person who was not a slave, and whose will consequently was not checked by the command of any master. The liberal arts, including under this name rhetoric, painting, sculpture, music, and architecture, used formerly to be summed up in the verse,

> Lingua, Tropus, Ratio, Numerus, Tonus, Angulus, Astra ;

and the mechanical arts, which are innumerable, under

> Rus, Nemus, Arma, Faber, Vulnera, Lana, Rates.

See the article Arts.

LIBERALIA, feasts celebrated by the ancient Romans, in honour of Liber or Bacchus, and the same with those which the Greeks called *Dionysiaca*. They derived their name from *liber*, free, a title conferred on Bacchus in memory of the liberty or freedom which he granted to the people of Bœotia; or, perhaps, because wine, of which he was the reputed deity, delivers men from care, and sets their minds at ease and freedom. Varro derives the name of this feast from *liber*, free, because the priests were free from their function, and eased of all care, during the time of the *liberalia;* as the old women officiated in the ceremonies and sacrifices of these feasts.

LIBERIA, an American colony, situated on the western coast of Africa. This territory was purchased from the native chiefs in 1821, by the American Colonization Society, for the purpose of forming an establishment for liberated negroes belonging to America, who, by the prejudices of the country, are regarded as beings of an inferior order. It is situated in that part of Africa called Grand Bassa, a part of the Grain Coast of Guinea, about 300 miles south of Sierra Leone; and its capital, which is called Monrovia, stands on an island at the mouth of the Mesurado, called Cape Mesurado or Montserrado, longitude 10. 36. 30. west, latitude 6. 15. 0. north. The territory presents the form of a narrow tongue of twelve leagues in extent, and is connected with the mainland by a narrow isthmus, formed by the approach of the head waters of the Montserrado and Junk Rivers. Cape Montserrado, the north-western termination of this linear tract of country, rises to a promontory sufficiently majestic to present a bold distinction from the uniform level of the coast. Towards the south-east, Liberia is terminated by the mouth of the Junk River. The country upon the coast is low, but it gradually rises towards the interior; and at a distance of from twenty to thirty miles from the sea, hills of considerable elevation are visible. It is fertile, healthy, and in every way adapted to the purpose for which it was obtained from the natives. About forty-eight miles due north-west from Cape Montserrado, is Grand Cape Mount, which rises from a level country, on a base of about four miles in diameter, about 900 feet above the sea, which washes it on three sides. This mount, the north-western extremity of Liberia Bay, is covered with a deep and unfading foliage. Several springs of excellent water descend from it, and the Pisson River empties itself into the ocean on its northern side. The St Paul's River, which flows into Liberia Bay, is of considerable magnitude, and is supposed to admit, above its falls, which are about twenty miles from its mouth, of boat navigation, for 200 or 300 miles. The Montserrado River is forty miles long, and enters the sea on the northern side of the cape of the same name. In the Junk district, south-east of Cape Montserrado forty miles, are two considerable rivers, which pour their waters into the ocean at the distance of only two miles from each other. The river St John's, eighty-one miles south-east from Cape Montserrado, is the largest of all, and navigable for vessels of from 90 to 100 tons, abounding with fish, and having its course through a fertile and salubrious country, of a rich soil. Cape Montserrado is elevated about eighty feet above the ocean, is washed on three sides by the water, is connected with a level tract of land on the fourth, and comprehends about 1600 acres. The town of Monrovia, the capital of the settlement, is situated on the inland side of the peninsula which forms the south-west bank of the river Montserrado, about two miles within the extremity of the cape. The original settlement approached within 150 yards of the water, and occupied the highest part of the ridge, which traverses a large part of the peninsula, and rises at this place to about seventy-five feet. A dense and lofty forest, entangled with vines and brushwood, so as to be nearly impracticable by any but the feet of savages and wild beasts, formed the majestic covering of a large portion of this tract, when the territory was purchased by the American Colonization Society.

Opposite the town of Monrovia, and near to the mouth of the Montserrado River, are two small islands, containing together about three acres of ground. The largest of these islands is nearly covered with houses built in the native style, and was for some time occupied by a number of domestic slaves, formerly held in a state of qualified vassalage, very common in Africa, by a black man, to whom the right of the original owner had devolved after his return to Europe. The tribes in the neighbourhood are, first, the Deys, who inhabit the coast from twenty-five miles to the northward of Montserrado, to the mouth of the Junk, about thirty-six miles to the south-eastward; contiguous to this nation, and next interior, are the Queahs, whose country lies to the east of Cape Montserrado; and, lastly, the Garrahs, a much more numerous race of men, who occupy the country to the northward of the upper parts of the St Paul River. Still farther towards the interior is the formidable and warlike nation of the Condoes, the terror of all their maritime neighbours. About a mile to the northward of the settlement, a portion of the beach is occupied by the Kroomen, who are the watermen and pilots of the country. They originate from a populous maritime tribe, whose country is Settra-Kroo, near Cape Palmas. The articles to be obtained by trade at Liberia are chiefly ivory, camwood, gold, tortoise-shell, hides, the teeth of the sea-horse, and a small quantity of coffee. The country abounds in cattle, goats, swine, and fowls, and in most of the fruits and vegetable productions of other tropical climates. The first efforts of the American Colonization Society were attended with considerable success. Great numbers of free people of colour were transported to Liberia, and some improvement was effected both in their condition and their character. Those who had been slaves were transformed into masters; and, from being a depressed and degraded being in America, the freed negro found himself raised to the level of those who had formerly been his task-masters and oppressors. In theory the plan of the American Colonization Society was excellent, and indeed it appears to be the only one by which civilization can be introduced into Africa. Natives of Africa alone possess physical constitutions which are proof against the climate; and to operate by a continuous force, as it were, is the only way to make an impression upon the country, or to effect a change in the moral deportment of its inhabitants. The scheme was not only praiseworthy, as far as the freed men of colour were themselves concerned, but in regard to the land of their nativity it might have effected an important change. Unfortunately, however, almost every prospect of success has been blasted by the native Africans, who, in 1835, attacked the colonists, and massacred a number of the inhabitants; and by the most recent accounts, it appears that they are in continual danger of entire extirpation.

Liberia, in Roman antiquity, a festival observed on the 16th of the kalends of April, at which time the youth laid aside their juvenile habit for the *toga virilis*, or habit peculiar to grown men.

LIBERTINES, Libertini, in ecclesiastical history, a religious sect which arose in the year 1525, and the principal tenets of which were, that the Deity was the sole operating cause in the mind of man, and the immediate author of all human actions; that, consequently, the distinctions of good and evil, which had been established with regard to those actions, were false and groundless; that men could not, properly speaking, commit sin; that religion consisted in the union of the spirit or rational soul with the Supreme Being; that all those who had attained this happy union, by sublime contemplation and elevation of mind, were allowed to indulge, without exception or restraint, their appetites or passions; that all their actions and pursuits were then perfectly innocent; and that, after the death of the body, they became united to the Deity. This sect likewise held that Jesus Christ was nothing but a mere entity, composed of the spirit of God, and of the opinion of men. These maxims occasioned their being called *Libertines;* and the word has been employed in a bad sense ever since.

The *Libertini* spread principally in Holland and Brabant. Their leaders were one Quintin, a native, Picards, Pockesius, Ruffus, and another person called Chopin, who joined Quintin, and became his disciple.

This sect obtained a certain footing in France through the favour and protection of Margaret, queen of Navarre, sister of Francis I., and it found patrons in several of the reformed churches. It was probably a remnant of the more ancient Beguards, or Brethren of the Free Spirit.

Libertines of Geneva, were a cabal of rakes rather than of fanatics; for they made no pretence to any religious system, but pleaded only for the liberty of leading voluptuous and immoral lives. This cabal was composed of a certain number of licentious citizens, intolerant of the severe discipline of Calvin, who punished with rigour not only dissolute manners, but also whatever bore the aspect of irreligion and impiety. In this turbulent cabal there were several persons who were not only notorious for their dissolute and scandalous manner of living, but also for their atheistical impiety, and contempt of all religion. To this odious class belonged one Gruet, who denied the divinity of the Christian religion, the immortality of the soul, and the difference between moral good and evil, and who rejected with disdain the doctrines that are held most sacred among Christians; impieties for which he was at last brought before the civil tribunal, in the year 1550, and condemned to suffer death. At this time the Genevan spirit of reformation, directed by the excessive zeal of Calvin, tended to defeat itself, and to introduce the greatest disorders. In 1544, Castalio, master of the public school of that city, a man of probity, and distinguished by his learning and taste, was, nevertheless, deposed from his office and banished the city, because he disapproved of some of the measures which were pursued, as well as of the opinions entertained by Calvin and his colleagues, particularly that of absolute and unconditional predestination. Jerome Bolsec, also a man of genius and learning, who became a convert to the Protestant religion, and fled to Geneva for protection, was cast into prison, and soon afterwards driven into exile, because, in 1551, he imprudently declaimed, in full congregation, against the doctrine of absolute decrees.

LIBERTUS, or Libertinus, amongst the Romans, a freedman, or a person set free from a legal servitude.

Persons of this class still retained some mark of their ancient state, he who made a slave free having a right of patronage over the *libertus;* so that if the latter failed in showing due respect to his patron, he was restored to his servitude, and if the *libertus* died without children, his patron was his heir.

In the early age of the republic, *libertinus* denoted the son of a *libertus* or freedman; but afterwards, that is, before the time of Cicero, and under the emperors, the terms *libertus* and *libertinus* were used as synonymous.

LIBERTY denotes a state of freedom, in contradistinction to slavery or restraint, and may be considered either as *natural* or as *civil.*

The absolute rights of man, considered as a free agent, endowed with a discernment to distinguish good from evil, and with a power of choosing those measures which appear to him to be most desirable, are usually summed up in one general appellation, and denominated the *natural liberty of mankind.* This natural liberty consists properly in a power of acting as one thinks fit, without any restraint or control, unless by the law of nature; being a right inherent in us by birth, and one of the gifts of God to man at his creation, when he endowed him with the faculty of free-will. But every man, when he enters into society, gives up a part of his natural liberty, as the price of so valuable a purchase; and, in consideration of receiving the advantages of mutual commerce and of protection, obliges himself to conform to those laws which the community has thought proper to establish. This species of legal obedience and conformity is therefore infinitely more desirable than that wild and savage liberty which is sacrificed to obtain it. For no man, who considers for a moment, would wish to retain the absolute and uncontrolled power of doing whatever he pleased, because every other man would have the same power, and then there would be no security to individuals in any of the enjoyments of life.

Civil liberty, therefore, which is that of a member of society, is no other than natural liberty, restrained by human laws, as far as is necessary and expedient for the advantage of the public. Hence we may collect, that the law, which restrains a man from doing mischief to his fellow-citizens, though it diminishes the natural, increases the civil liberty of mankind; but every wanton and causeless restraint of the will of the subject, whether practised by a monarch, a nobility, or a popular assembly, is a degree of tyranny. Even laws themselves, whether made with or without our consent, if they regulate and constrain our conduct in matters of mere indifference, without any good end in view, are laws destructive of liberty; but if any public advantage can arise from observing such precepts, the control of our private inclinations, in one or more points, will conduce to preserve our general freedom in others of more importance, by supporting that state of society which alone can secure our independence. Thus the statute of Edward IV. which forbade the fine gentlemen of his time to wear pikes upon their shoes or boots of more than two inches in length, was a law that savoured of oppression, because, however ridiculous the fashion then in use might appear, the restraining it by pecuniary penalties could serve no purpose of general utility. But the statute of Charles II. which prescribed a thing apparently as indifferent, viz. a dress for the dead, who were ordered to be buried in woollen, was a law consistent with public liberty; for it encouraged the staple trade, on which in great measure depended the prosperity of the nation. Hence laws, when prudently framed, are by no means subversive, but rather introductive, of liberty; for, as Mr Locke has well observed, where there is no law there is no freedom. But then, on the other hand, that system of laws is alone calculated to maintain civil liberty, which leaves the subject entire master of his own conduct, excepting as to those points in which the public good requires some direction or restraint.

The idea and practice of this civil liberty flourish in their highest vigour in these kingdoms, where it falls little short of perfection, and can only be lost or destroyed by the folly or demerits of its owner; the legislature, and of course the laws of Britain, being peculiarly adapted to the preservation of this inestimable blessing even in the meanest subject. And this spirit of liberty is so deeply implanted in our constitution, and rooted even in our very soil, that a slave or a negro, the moment he lands in Britain, falls under the protection of the laws, and so far becomes a freeman, though his master's right to his service may possibly still continue.

The absolute rights of every Briton, as they are founded on nature and reason, so they are coeval with our form of government, though subject at times to fluctuation and change; their establishment, excellent as it is, being still human. At some periods we have seen them depressed by overbearing and tyrannical princes; at others, so luxuriant as even to tend to anarchy, a state worse for the time than tyranny itself, as any government is better than none at all. But the vigour of our free constitution has always delivered the nation from these embarrassments; and, as soon as the convulsions consequent on the struggle have ceased, the balance of our rights and liberties has settled at its proper level; whilst their fundamental articles have been asserted in parliament, as often as they were thought to be in danger. See the articles GOVERNMENT and LEGISLATION.

LIBERTY and Necessity. See METAPHYSICS.

LIBERTY OF THE PRESS.

I.—NATURE AND OBJECTS OF THE INQUIRY.

THE task of pointing out which of the acts, capable of being committed by the press, it would be expedient to prohibit under penalties, we trust will be found to be greatly diminished, by what we have already established in the articles GOVERNMENT and JURISPRUDENCE.

There is scarcely a right, for the violation of which, scarcely an operation of government, for the disturbance of which, the press may not be employed as an instrument. The offences capable of being committed by the press are indeed nearly co-extensive with the whole field of delinquency.

It is not, however, necessary to give a separate definition of every such violation or disturbance, when committed by the press; for that would be to write the penal code a second time, first describing each offence as it appears in ordinary cases, and then describing it anew for the case in which the press is the particular instrument.

If, for the prevention of the violation of rights, it were necessary to give a separate definition, on account of every instrument which might be employed as a means of producing the several violations, the penal code would be endless. In general, the instrument or means is an immaterial circumstance. The violation itself, and the degree of alarm which may attend it, are the principal objects of consideration. If a man is put in fear of his life, and robbed of his purse, it is of no consequence whether he is threatened with a pistol or with a sword. In the definition of a theft, of a fraud, or of a murder, it is not necessary to include an account of all the sorts of means by which these injuries may be perpetrated. It is sufficient if the injury itself be accurately described. The object is to prevent the injury, not merely when produced by one sort of means or another sort of means, but by any means.

From these illustrations, it sufficiently appears, that, if an accurate penal code were composed, defining the violations of rights, and the disturbances of the operations of government, to which penalties were to be annexed, every offence capable of being committed by the press would be defined without mentioning the press. It is no less evident, that if we include in the term *libel*, as, to the great encouragement of confusion, is generally done, all the offences capable of being committed by the press, we include in the definition of libel all the definitions of the penal code.

As far as persons and property are concerned, the general definition of the acts by which rights are liable to be violated, has always been held sufficient; and has been regarded as including not less the cases in which the instrumentality of the press has been employed, than those in which any other means have been employed to the same end. Nobody ever thought of a particular law for restraining the press on account of the cases in which it may have been rendered subservient to the perpetration of a murder or a theft. It is enough that a law is made to punish him who has been guilty of the murder or theft, whether he has employed the press or any thing else as the means for accomplishing his end.

There can be no doubt, however, that the press is an instrument peculiarly adapted for the commission of injuries against reputation, and for effecting disturbance to the operations of government, while it has no peculiar adaptation for the commission of other offences. Here, too, there is the greatest disposition to restrain the press within improper limits. It is demanded of us, therefore, upon this part of the subject, to enter into greater detail.

We are then to inquire, in the first place, What are the acts of the press with respect to *private reputation;* and next, What are the acts with respect to *government,* which it is desirable that punishment should be employed to restrain.

II.—OFFENCES OF THE PRESS, WITH RESPECT TO PRIVATE RIGHTS.

Agreeably to the principles which have been already considered in the article JURISPRUDENCE, no act can be regarded as an offence with respect to an individual, which is not a violation of some of his rights.[1]

---

[1] In the description which follows of that violation of rights which is most liable to be committed by the press, and of the mode

Liberty of the Press.

In considering the rights which ought to be established with respect to reputation, one proposition may be assumed; that every man should be considered as having a right to the character which he deserves; that is, to be spoken of according to his actions.

Such Offences should be defined.

In what manner the definition of this right, which would form a part of the civil code, should be expressed, is not now the question; it is evident there is no peculiar difficulty in the matter. As words, not thoughts, are the object of legal cognizance, the right can only have respect to security against certain words; words, imputing to the individual actions which he has not performed, or a disposition to certain actions, without evidence that such a disposition exists.

Suppose that one man has instituted a suit against another, for the offence of having violated, through the press, his right to some part of the reputation which he deserves. In his ground of complaint he must affirm that the man has imputed to him either the performance of actions which he did not commit, or a disposition to certain actions, where no evidence of such disposition can be given.

The words are produced; and the first question is, whether they do or do not impute the actions which, in the complaint, or bill of accusation, they are alleged to impute?

It is to be observed, that they who oppose the attempt to define the offences, which, for shortness, we call the offences of the press, make use of such occasions as this to raise their objections. How, they ask, can all the forms of expression be defined, by which the imputation of such and such actions may be, either more openly, or more covertly, conveyed?

It is very evident that the question, on such an occasion, whether the words do or do not impute such or such actions, is a question of fact. The law says, that such and such actions shall not be imputed, defining the actions. Whether such and such a man has imputed such actions, and whether by one set of words, or another set of words, are questions of fact.

The law, when it said that such and such acts should not be imputed to a man, could not determine whether A, who is accused by B of having imputed to him one of those acts, did so or not. That is to be determined by evidence bearing upon the point. One, and in general the main article of that evidence, are the words which have been used. What is the import of these words, or, which comes to the same thing, what is the degree of proof involved in them, is to be determined, as all questions respecting the weight of evidence are, in each instance, to be determined, by the tribunal before which the accusation is brought. The interpretation of words rests upon the same footing in this, as in all other cases, that, for example, of a will. The law determines, that whatsoever disposition a man has made with respect to his property, shall take effect after his death. But whether A has left his manor of Dale to B, is a matter of fact to be determined by evidence applying to that particular point; principally by that arising from the words of the will.

It may still be argued, by persons who do not easily renounce an opinion to which they have once given their support, that the actions, the imputation of which, the legislature means to prohibit, cannot be defined.

But this is a position which cannot long be maintained.

It is hurtful to a man, if he is believed to have committed some actions, or to have a disposition to commit them; it is not hurtful in the case of others. Evidently it is by imputation of the first sort alone, that any right with respect to reputation can be infringed.

The acts which a man receives injury from being believed to have committed, or to be disposed to commit, are either those to which the law has annexed penalties, or those to which the penalties of public disrepute and dislike are annexed.

With respect to those acts to which the law has annexed penalties, as theft, murder, perjury, and so on, it will not be pretended that there is any difficulty; the law has already defined them, or ought to define them, and they may be marked with perfect precision by a few words.

Those acts which it is hurtful to a man, solely on account of the disrepute and dislike which they produce, to have it believed that he has committed them, may also be with sufficient accuracy determined.

Compensation should be made to the Individual for Injuries sustained by Offences of the Press.

The ends to be attained by punishment are, Reparation to the individual to whom injury has been done, and Prevention of similar acts in future.

In the idea of all punishment, effectual reparation to the injured individual is a necessary and essential ingredient. Suppose, then, it were declared by the legislature that every imputation to a man of acts which bring the evil of dislike and disrepute upon him who has committed them, that is, every false imputation, shall be punished at least by reparation to be made to the party injured; the term *evil* is to this purpose perfectly precise. It would remain with the complainant to show what kind and degree of injury he had received; which is a matter of fact, to be estimated, in each instance, from the evidence adduced, by the tribunal before which the question is brought. If the injury sustained is a pecuniary injury, the question coincides exactly with the question of damages, decided regularly, in English courts, as a question of fact, by the jury.

Injuries of the kind which we are now considering can affect a man only in two ways; either by lessening the pecuniary value which he might otherwise have enjoyed, or by lessening the marks of respect and affection which he would otherwise have received. What the loss is, in this latter instance, is also evidently a question of fact. It has nothing, therefore, to do with the legal definition of the offence, the business of the legislature. It is a question, which, like other questions of fact, must of necessity be determined upon evidence by the tribunal before which it is brought. It is no doubt a question of delicacy, and considerable difficulty, because the evidence must often consist of very fine and minute circumstances, which can seldom be precisely ascertained. But this is not the only class of judicial questions, the determination of which depends upon such evidence as it is very difficult accurately to collect and to weigh. What is of greatest importance, on this occasion, to remark, is, that all the difficulty lies in the matter of fact. There is no doubt or obscurity in the law, which says, that whatsoever hurt a man has sustained through actions or dispositions falsely imputed to him, he shall receive compensation for. Difficulties, however, arising either from the complexity of the matter of fact, or the obscurity of the evidence, no legislative enactments can prevent. These are confided to the skill and integrity of the judge.

The compensation which ought to be made to a man for the diminution of those marks of respect and affection which he would otherwise have received, is a question for

---

n which it ought to be treated, the developments presented in the article Jurisprudence are understood to be present to the mind of the reader; if they are not, the very brief exposition here given will not be understood.

the legislature. Let us suppose that a soldier has been accused of cowardice, in such a manner as to create a general belief of the truth of the accusation; that a man of honour has been accused of mendacity, or of some of those irregular propensities to which the horror of the public is attached; it is evident that money is not, in such cases, an appropriate compensation.

When a man, through the offence of another, has been deprived of a certain amount of money, or of money's worth, we say that he has received compensation, when he is placed in the same situation in which he would have been if the offence had never taken place.

According to this idea of compensation, a man, against whom an unfavourable opinion has been created by the act of another man, has received compensation, when he is placed in the same situation with regard to the opinion of those with whom he is connected, as if that act had not taken place. This, therefore, is the object which it ought to be the endeavour of the legislature to effect.

One expedient is perfectly appropriate. It is, that the man who has falsely propagated an unfavourable opinion with respect to another, should be made to do whatever is in his power to remove the impression he has made. To this end, he should publish the sentence of the judge, declaring that the action or disposition which he had imputed to the individual injured, he had imputed to him falsely. He should at least be made to publish it in every way in which he had published the imputation. Frequently a more extensive publication might be required.

In some cases, it will be allowed, that thus much would suffice. It may, however, be affirmed, that often the impression would be too profoundly struck, to be effaced by a mere knowledge of the sentence of the judge. In such cases, something more in the way of compensation would be required. On this, it is of importance to be observed, that if the impression produced by an imputation, which, after solemn inquiry, the judge has declared to be false, should not, by that declaration, be completely effaced, it implies necessarily one of two things; either that the public have evidence of the truth of the accusation, which was not adduced to the judge, and then the remaining impression is not owing to the imputation which the judge has condemned, but to the evidence; or, secondly, that the public mind is in a state of gross ignorance and imbecility, capable of forming opinions, even on the clearest subjects, not only not according to evidence, but in opposition to it. If the public mind, however, is in such a deplorable condition, it is the fault of the legislature; and for the rectification of this evil, the best course undoubtedly is, to take effectual measures for the instruction of the people, which instruction would soon place them beyond the danger of such delusions. In the mean time, if something more than the publication of the sentence of the judge were necessary to restore a man to that degree of consideration, of which the false imputation had deprived him, governments have numerous ways of raising the consequence of individuals; and no legislature would be at a loss for a gradation of expedients suited to the scale of demand.

Means which should be used for preventing the Violation of Rights by the Press.

We have now illustrated that part of this question which regards compensation to the injured individual. It remains to inquire what is best to be done in this case, for the attainment of the other object of punishment, namely, the prevention of similar offences in time to come.

To devise a punishment sufficient to prevent an offence, is to provide a motive sufficient to counteract the motive which leads to the offence. We have hence to consider what are the motives by which men are incited to make false imputations on the characters of others.

These motives may be of three different sorts. A man may derive *pecuniary profit*, he may derive *comparative distinction*, or he may satisfy his desire of *vengeance* by blackening the character of his neighbour.

In the case in which a man has by calumny wrongfully intercepted the pecuniary receipts of his neighbour, the obligation of making satisfaction to the party injured would, it is obvious, alone suffice, provided the machinery of the laws were sufficiently perfect to render the execution of them certain. Seldom would any man calumniate his neighbour for the sake of placing L.20 in his own pocket, if he were sure that, next day, or next week, he would have to restore it, with all the profit which might have been made by the use of it, and with the disgrace besides of having committed an action which other men abhor.

Sometimes, however, a man may derive pecuniary profit from calumniating persons whom he has not by that means deprived of any pecuniary advantage; by the sale, for example, of a slanderous publication; when the satisfaction due to the individual may not be of a nature to counteract the motive which leads to the offence. The expedient in this case, also, is sufficiently obvious, and sufficiently simple. It is necessary to ascertain the whole of the gain which has been made by the offender, and to take it away from him. This, together with the satisfaction which he ought to make to the injured individual, would, if it were certain, create a surplus of motive to abstain from the injurious act.

In both of these cases, if the execution of the law is uncertain, an additional punishment may be necessary, sufficient to compensate for the chance of escape. The allowance to be made on this score must depend upon the imperfection of the laws; while one important fact is to be kept in remembrance, that as severity of punishment, beyond a certain point, is increased, certainty of execution is diminished. The true expedient, therefore, is to render the machinery of the laws so perfect, that the penalties which they denounce may always be sure of execution; and then hardly any thing beyond compensation to the individual, and the abstraction of any additional gain which might have been made by the propagation of slander, would be necessary to repress all offences against the reputation of others, to which the motive was constituted by pecuniary gain.

The two remaining cases are still more simple. If a man propagates a falsehood, for the sake of injuring the character of a man by whom his own consideration is eclipsed, it is only when he expects to obtain by that means a permanent advantage. If he knows that immediately the law will take its hold upon him; that he will be compelled to re-elevate the character of his neighbour, and to proclaim his own disgrace, he will see that, to attempt depressing the character of another man by calumny, is the very worst of all expedients for giving a comparative elevation to his own. The same is the result in the case where vengeance constitutes the motive to injure the reputation of another. To render this proposition manifest, the most obvious illustration will suffice. No man, to gratify his malignity to another person, would kill his ox or his ass, provided he were sure that immediately he would be obliged to make him full satisfaction; and instead of injuring the man whom he hated, to injure only himself. No, the rudeness and inefficacy of the law, holding out a chance of escaping the duty of making reparation, is the sole origin and cause of all offences of this description; and if the law were placed in a state but approaching to perfection, hardly any thing beside the obligation of making satisfaction would be necessary to repress the whole of this order of crimes.

Whether any Imputation by which Truth is not violated, should be considered an Offence by the Press.

We have now made considerable progress in this important inquiry. We have ascertained, we think, with sufficient evidence, all that is necessary to be done for preventing injuries to the reputation of individuals; provided the rights of reputation are not, by the civil code, made to extend beyond the boundaries of truth. Whether or not they ought to extend farther, and individuals ought to be protected from the disclosure of acts which they may have committed, is, we confess, a question highly worthy of solution; upon which, therefore, before we proceed to any of the subsequent topics, we shall offer the following reflections.

There can be no doubt that the feelings of the individual may be as painful, where actions of a disreputable nature are truly, as where they are falsely, imputed to him. It is equally certain, that no painful feelings ought to be wilfully excited in any man, where no good, sufficient to overbalance that evil, is its natural consequence.

We have already shown, that reputation is injured by the imputation of acts of two different descriptions; first, those to which the law annexes penalties; secondly, those to which disrepute and the dislike of others are annexed.

With respect to those acts to which the law annexes penalties, there is no room for uncertainty or dispute. Unless the law is a bad law, which ought to be repealed (this, we confess, constitutes an exception, and one which, in very imperfect codes, extends a great way), the law ought not to be disappointed of its execution. The man who gives information against a murderer, or a thief, by the press, or without the press, renders a public service, and deserves not punishment, but reward.

It appears, therefore, that the question, whether a man ought to be protected from the imputation of actions which he has really committed, refers solely to those acts which, without being punishable by the law, are attended with disrepute; acts, in other words, which the members of the society disapprove and dislike.

The prospect of the immediate and public exposure of all acts of this description, would be a most effectual expedient to prevent their being committed. Men would obtain the habit of abstaining from them, and would feel it as little painful to abstain, as at present it is to any well educated person to keep from theft, or those acts which constitute the ill manners of the vulgar. The fable of Momus has always been understood to carry an important moral. He found grievous fault that a window had not been placed in the breast of every man, by which, not his actions alone, but his thoughts, might have been known. The magnanimity of that Roman has been highly applauded, who not only placed his residence in such a situation that his fellow-citizens might see as much as possible of his actions, but declared a wish that he could open to all eyes his breast as well as his house.

If the hatred and contempt of the people, therefore, were always rightly directed, and rightly proportioned,—if they never operated against any actions but those which were hurtful, either to the individual himself, or to others, and never, but in the degree in which they were hurtful,—the case would be clear; the advantage which would be derived from the true exposure of any man's actions of any sort, would exceed beyond calculation the attendant evil. The great difficulty of insuring the practice of morality, in those numerous and highly important cases to which the legal sanction, or the *security of pains and penalties*, does not extend, consists in the want of a motive always present, and powerful enough to counteract the instant motive which urges to the instant offence. That motive almost every man would derive from the knowledge that he had the eyes upon him of all those the good opinion of whom it was his interest to preserve; that no immoral act of his would escape their observation, and a proportionate share of their hatred and contempt. It is in this view that the aid of religion has been sometimes regarded as of importance to morality, suggesting the idea of a high and constant observer. All motives, however, are feeble, in proportion as the pains and pleasures upon which they depend are distant, vague, or uncertain. Divines agree with all other men in complaining of the trifling effect of religious motives upon the lives of the greater number of men. From the nature of the prospect on which these motives depend, they could not be less feeble than they have been thus described. The case is not the same with the motives arising from the sentiments which we know we shall inspire in the breasts of our fellow-creatures. It is a matter of daily and incontrovertible experience, that these are among the most powerful which operate upon the human mind. The soldier rushes upon death, and endures all the hardships and toils of his cruel profession, that he may enjoy the admiration and escape the contempt of his fellow-men. On what else is founded the greater part of all human pursuits? How few, even of those who toil at the meanest occupations, but exert themselves to have something for show, something to make an impression upon the eyes of those who surround them? The very subject of the present inquiry derives from this source the whole of its importance. The value of reputation is, indeed, but another name for the value which we attach to the favourable and unfavourable sentiments of our fellow-men.

It is, however, true, that their unfavourable sentiments do not always fall where they ought; and this, we confess, is a consideration of the highest importance. It very often happens that men's antipathies are excited to actions from which no evil ensues, either to him who performs them, or to any body else. If any man derives a pleasure from such actions, it is to limit his sphere of innocent enjoyment to debar him from them. And if the press exposes him to the antipathies, the hatred, and contempt of his fellow-creatures, on account of those actions, it produces an evil, uncompensated by the smallest portion of good. To an Indian Brahmin, if he were known to have eaten, even when starving, a morsel of food which had been prepared by a Christian, the consequences would be dreadful. Where the Roman Catholic religion is in vigour, a man who should indulge himself in animal food on forbidden days would be regarded with horror. The use of wine, however moderate, would render a Mahommedan execrable to the whole of his tribe.

This misdirection of the favourable and unfavourable sentiments of mankind; in other words, this perversion and corruption of their moral sentiments, has, in by far the greater number of instances, been the work of priests, contriving the means of increasing their influence. In some very important instances, such, for example, as the prejudices of birth, at one time in Europe so powerful as to make men of low birth objects of the greatest contempt, men of elevated birth objects of the highest veneration, the perversion of the moral sentiments is evidently the work of the aristocratical class, securing to themselves a more easy dominion over the rest of their fellow-creatures.

It is, therefore, evident, that where antipathies, religious or aristocratical, should prevail, the press would be hurtfully employed in giving notoriety to the facts which would expose a man to the operation of either.

We have now ascertained the cases in which it would *not* be good that men should be protected from the declaration of truth by the press, and also the cases in which it *would* be good that they should be so protected.

What, upon this view of the subject, would be desirable, is sufficiently clear. It would be desirable that, in the one set of cases, the declaration should be allowed, in the other it should not be allowed. Are the two sets of cases, however, capable of being accurately distinguished?

If the comparison is made with any attention, it will not be difficult to determine that the evil to be incurred by the loss of truth in the set of cases in which the declaration of it would be useful, is much greater than that which would arise from permitting the declaration in the cases in which it would be hurtful.

In the first place, the set of cases in which the declaration would be useful are much more numerous, and much more important, than those in which, in any tolerably civilized state of society, it would be hurtful. Those in which it would be useful embrace the whole field of morality, all those acts, the performance of which, on account of their singular importance, has been elevated to the rank of virtues. Every body believes and proclaims, that the universal practice of the moral virtues would insure the highest measure of human happiness; no one doubts that the misery which, to so deplorable a degree, overspreads the globe, while men injure men, and, instead of helping and benefiting, supplant, defraud, mislead, pillage, and oppress one another, would thus be nearly exterminated, and something better than the dreams of the golden age would be realized upon earth. Toward the attainment of this most desirable state of things, nothing in the world is capable of contributing so much as the full exercise of truth upon all immoral actions, that is, all actions, the practice of which is calculated to lessen the amount of human happiness. According to this view, the justice of which it is impossible to dispute, the evil incurred by forbidding the declaration of truth upon all immoral actions is incalculable. That which would be incurred by the antipathies of misguided minds against actions innocent in themselves, nobody, we should imagine, would so much as think of placing in comparison.

In our own country, for example, the classes of actions which, though they injure nobody, expose a man to the unfavourable sentiments of others, are not numerous. The number of persons who would be exposed to inconvenience on account of the declaration of truth in regard to them, would be small in comparison with those who would benefit by its declaration in the case of all really hurtful acts.

It is, indeed, important to be observed, that a comparative smallness of number is necessarily implied in the supposition of injury from any unfounded antipathy. Those who share in the antipathy, of course, abstain from the action. And unless the antipathy were so general as to include almost the whole of the society, it would lose its injurious effect. Besides, all the injury which can be done to the individuals against whom truth would in this manner operate injuriously, would be, to make them abstain from the acts which were thus condemned.

Another thing to be considered is, that the whole of the evil arising from the exercise of truth is dependent upon an accidental circumstance, capable of being removed; upon a mental disease, requiring to be cured, which the legislature ought to be constantly endeavouring to cure, and toward the cure of which truth is likely to operate as the most effectual of all expedients. If any considerable inconvenience were experienced from exposure to unfounded antipathies, in consequence of the publication of truth, the groundlessness of these antipathies could not fail in this case to be so often canvassed, and made to appear, that at last it would become familiar to the multitude, and the antipathies would expire.

It clearly, therefore, appears, that, if the cases in which the declaration of truth would expose to unfounded prejudices could not be clearly defined, and separated from the cases in which the declaration would be salutary, the rule of permitting truth ought to be universal. But, though we perceive, that, to a considerable extent, there are cases, in respect to which it would be vain to hope for agreement in drawing the line of distinction between what is hurtful and what is not, we are persuaded that principles might be laid down in which all would agree, and which would serve to mark out certain cases for exception with sufficient exactness. If any such cases could be separated, either of actions, which, though injurious to nobody, excited antipathies, or of facts, as those of birth, for which, though a man was in no respect worse, he might be regarded as worse; the exercise of truth, with regard to them, might, on the express ground that they were actions innoxious, or facts which ought to be of no importance in the estimate of human worth, be forbidden, when injurious, under the penalty of at least making reparation for all the injury of which it had been the cause.

III.—OFFENCES OF THE PRESS WITH RESPECT TO GOVERNMENT.

We have now explained, we trust with sufficient clearness for the present occasion, the principles upon which laws should be constructed for protecting the *rights of individuals* against violations committed by the press. The first part of this inquiry, therefore, we must consider as completed. In the second part we have to explain the principles upon which they should be constructed for protecting *the operations of government.*

Exhortations to obstruct the Operations of Government in detail should, Exhortations to resist all the Powers of Government at once should not, be considered Offences.

Unless a door is left open to resistance of the government, in the largest sense of the word, the doctrine of passive obedience is adopted; and the consequence is, the universal prevalence of misgovernment, insuring the misery and degradation of the people. On the other hand, unless the operations of government, instituted for the protection of rights, are secured from obstruction, the security of rights, and all the advantages dependent upon the existence of government, are at an end. Between these two securities, both necessary to obtain the benefits of good government, there appears to be such a contrariety, that the one can only be obtained by the sacrifice of the other.

As this difficulty, however, arises chiefly from the extent of the terms, a close inspection of the cases which they involve, and which they have a tendency to confuse, will enable us to discover the course which it belongs to practical wisdom to pursue.

It is necessary, first of all, to ascertain what sort of obstructions are inconsistent, and what are not inconsistent, with those operations of government which are necessary for the protection of rights.

The application of physical force to resist the government in applying to the execution of the laws the physical power placed at its disposal by the law, is such an obstruction of the operations of government, as would, if frequent, render it inadequate to the ends which it is provided to secure. This application of force, therefore, must be treated as an offence; and any thing proceeding from the press, tending directly to produce it, as a similar offence.

This proposition requires to be illustrated. The application of physical force which is here described, and treated as an evil, is clearly distinguishable from that resistance of government which is the last security of the many against the misconduct of the few. This is an application of physical force to obstruct the operations of government in detail; the proceedings, for example, of a court of justice; the proceedings of the legislative organ, or the proceedings of any of the administrative functionaries, in the execution of the duties with which they are charged. This is not that species of resistance which is necessary, in the last resort, to secure the people against the abuse of the powers of government. This last is not a resistance to the operations of government in detail. It is a resistance to all the powers of government at once, either to withdraw them from the hands in which they have hitherto been deposited, or greatly to modify the terms upon which they are held.

Even this last species of resistance it may be necessary to punish, at least in a certain degree, whenever it is not successful; that society may not be disturbed by commotions which the majority of the people disapprove. This, however, is a question which belongs to the penal code in general, and does not concern the inquiry into the offences capable of being committed by the press; because we think it may be satisfactorily shown, that no operation of the press, however directly exhorting to this species of resistance, ought to be treated as an offence.

The reason is, that no such exhortation can have any immediate or formidable effect; can, indeed, have any effect at all, except through such mediums as ought to be at all times perfectly free. Suppose that a work is published, exhorting the people in general to take arms against the government, for the purpose of altering it against the consent of its rulers. The people cannot take arms against the government without the certainty of being immediately crushed, unless there has been already created a general consent. If this consent exists in such perfection as to want nothing to begin action but an exhortation, nothing can prevent the exhortation; and forbidding it is useless. If the consent does not exist in nearly the last degree of perfection, a mere exhortation, read in print, can have no effect which is worth regarding. In all circumstances, therefore, it is useless, and consequently absurd, to treat this species of exhortation as an offence. If, on the other hand, it were clearly recognised, that every man had a license to exhort the people to the general resistance of the government, all such exhortations would become ridiculous, unless on those rare and extreme occasions on which no prohibitions and no penalties can or ought to prevent them. The doctrine of this paragraph, which will appear somewhat startling and paradoxical to minds accustomed only to a certain train of ideas, will receive illustration, and we trust will be amply confirmed, as we proceed.

Having mentioned this as a grand exception, we now return to the cases in which not only physical force applied to obstruct the operations of government, but the publishing of exhortations to that obstruction, ought to be treated as an offence. These relate solely, as above remarked, to the operations of government in detail. Obstructions, it is evident, may be offered to the operations in detail of a government which possesses and deserves the fullest confidence of the community at large; and the press may be employed in directly and efficiently exciting to these obstructions. A hand-bill, for example, distributed at a critical moment, and operating upon an inflamed state of mind, in a narrow district, may excite a mob to disturb the proceedings of a court of justice, to obstruct public officers in the execution of their duties, or even to disturb, on this or that occasion, the deliberations of the legislature itself.

These are clearly hurtful acts; they may be very accurately defined; and penalties, of moderate severity, would be sufficient to deter from the performance of them. Satisfaction by the party offending to the party injured, would often, in offences of this description, be out of the question; because there would be no definite party to whom an injury would be occasioned. It would only be necessary to ascertain the sorts of motives by which such offences would be liable to be produced, and to apply skilfully, as in other cases, motives of an opposite tendency, sufficient to counteract them. This would not be more difficult in this than in other cases, and it is not, therefore, necessary to explain at any length the mode of performing it.

One principle is to be carefully and most religiously observed, that of not imposing an atom of punishment for the purposes of *vengeance*. This is a principle, the justness and importance of which are so completely recognised, that we might have expected to be relieved ere now from the necessity of recommending attention to it. The fact, however, is, that so long as there are abuses in governments, so long will the men, who have the means of profiting by those abuses, exert themselves to multiply the list of offences against government, and to apply to them punishments of the greatest severity.

Punishments for contempt of court; punishments to vindicate the honour of the court, of the government, of the magistracy; punishments for the support of dignity; punishments severe in proportion as the dignity of the party offended is supposed to be high, and so on, are punishments almost always applied for purposes of vengeance, or the protection of the instruments of abuse. They are punishments, therefore, which will be rigidly excluded from a code which wisely and steadily pursues the general good.

Of Exhortations to obstruct the Operations of Government in detail, there are two Sorts: 1. The Direct; 2. The Implied, or Constructive.

What the *sort of acts* are, to which the exhortations of the press ought not to be applied, has been so far ascertained. The next point is, to determine with accuracy what *sort of exhortation* it is that ought to be forbidden.

To all those who profit by the abuses of government, that is, more especially, to all those who, in a defective government, wield any of its powers, it is of great importance to leave as undefined as possible the sort of exhortation that ought to be forbidden. The point of greatest importance to them is, to keep the people at large from complaining, or from knowing or thinking that they have any ground of complaint. If this object is fully attained, they may then, without anxiety, and without trouble, riot in the pleasures of misrule: there is no limit to the degree in which the few may pursue their own advantage at the expense of the many.

There can be nothing, therefore, in which they have a greater interest, than preventing the press from being employed in any such way as will lead the people to think that they have any thing, on the part of their rulers, of which to complain. All artifices possible will be sure to be employed to effect that prevention. And if it is enacted, that exhortations to acts which obstruct the operations of government in detail should be punished, *without defining accurately what sort of exhortations*, they will easily find expedients; which will, to a great extent, accomplish their purpose.

Under the sort of constructions which it will be their interest to apply, every thing which can be done by the press to make the people know or believe that there is any thing in the system of their government, or the conduct of their rulers, of which they have to complain, may be treated as an exhortation to obstruct the operations of government. Of these constructions our experience affords innumerable examples. Does not the imputing of defects to the government, or misconduct to those who wield the powers of government, tend to bring both " into hatred and contempt?" And if the people hate and contemn the institutions and rulers of their country, will they not oppose their operations? The imputing of these faults, therefore, is it not, in essence and effect, an exhortation to oppose the operations of government? And are we to be governed, in our legislature, by the mere forms in which a set of words may appear, and not by our knowledge of their nature and consequences?

This is not only exceedingly plausible, but almost all the propositions which it involves are true. It is thus, therefore, the more easy to establish such a mode of interpreting an indefinite law of the press, as will prevent, or, where the people cannot yet bear a total prevention, will go far towards preventing, whatever can lead the people to believe that any thing is amiss in the manner in which they are ruled.

There are two species of exhortations, the one explicit and direct, the other implied and constructive. In the one, a particular act is pointed out, and the party or parties addressed are called upon to perform it. In the other, certain grounds are only laid, from which the opinion of the addresser, that the act ought to be performed, may, with more or less certainty, be inferred.

With respect to the first, there is no occasion for doubt. A direct and explicit exhortation to commit one of those acts, described above as obstructing the operations of government in detail, should be treated as an offence. The precise question is, whether any exhortation, which is only implied and constructive, should be considered an offence? In the answer to this question, almost every thing which relates to the use of the press in matters of government will be found to be involved.

Exhortations which are Implied and Constructive, ought not to be punished.

We have already divided the subject of resistance to government into two parts; first, that general resistance, the object of which is some great change in the government at large; and, secondly, resistance to this or that of its operations in detail.

We have already adduced an argument, which appears to us to be conclusive, to show that no exhortation, whether explicit or implied, direct or indirect, the object or tendency of which is to produce the first species of resistance, ought to be subject to legal restraint.

It is necessary here to enter a little more fully into the grounds of that opinion.

We think it will appear, with sufficient evidence, that, in the way of indirect exhortation to resistance, that is, in laying the grounds of dissatisfaction with the government, there is no medium between allowing every thing and allowing nothing; that the end, in short, which is sought to be gained, by allowing any thing to be published in censure of the government, cannot be obtained, without leaving it perfectly free to publish every thing.

The end which is sought to be obtained by allowing any thing to be said in censure of the government, is, to censure the goodness of the government; the most important of all the objects to the attainment of which the wisdom of man can be applied. If the goodness of government could be insured by any preferable means, it is evident that all censure of the government ought to be prohibited. All discontent with the government is only good, in so far as it is a means of removing real cause of discontent. If there is no cause, or if there is better means of removing the cause, the discontent is, of course, an evil, and that which produces it an evil.

So true it is, however, that the discontent of the people is the only means of removing the defects of vicious governments, that the freedom of the press, the main instrument of creating discontent, is, in all civilized countries, among all but the advocates of misgovernment, regarded as an indispensable security, and the greatest safeguard of the interests of mankind.

For what is meant by a vicious government? or wherein do the defects of government consist? Most assuredly they all consist in sacrificing the interests of the many to the interests of the few. The small number, in whose hands the powers of government are, in part directly, in part indirectly, placed, cannot fail, like other men, to have a greater regard for what is advantageous to themselves, than what is advantageous to other men. They pursue, therefore, their own advantage, in preference to that of the rest of the community. That is enough. Where there is nothing to check that propensity, all the evils of misgovernment, that is, in one word, the very worst evils by which human nature is afflicted, are the inevitable consequence. (See the article GOVERNMENT.)

There can be no adequate check without the freedom of the press. The evidence of this is irresistible. In all countries, the people either have a power legally and peaceably of removing their governors, or they have not that power. If they have not that power, they can only obtain any considerable ameliorations of their governments by resistance, by applying physical force to their rulers, or, at least, by threats so likely to be followed by performance, as may frighten their rulers into compliance. But resistance, to have this effect, must be general. To be general, it must spring from a general conformity of opinion, and a general knowledge of that conformity. How is this effect to be produced, but by some means, fully enjoyed by the people, of communicating their sentiments to one another? Unless where the people can all meet in general assembly, there is no other means of attaining this object, to be compared with the freedom of the press.

It is, no doubt, true, that in countries where the liberty of the press is unknown, bad governments are frequently overthrown. This is almost always accomplished by the military force, revenging some grievance of their own, or falling in with some heat and animosity of the people. But does it ever enable them to make a new government, in which any greater security is provided for their interests than there was before? In such cases, the people get rid of one set of rulers, whom they hate, only to obtain another set, with equal powers of doing them injury.

There are, however, we believe, some people who say, that though the liberty of the press is a necessary instrument to attain good government, yet, if it is fairly attained, and if legal and peaceable means are in the hands of the people of removing their governors for misconduct; if the people of England, for example, really chose the members of the House of Commons, and renewed their choice so frequently, as to have the power of removal after a short experience of misconduct; the freedom of the press would be unnecessary.

So far is this from being true, that it is doubtful whether a power in the people of choosing their own rulers, without the liberty of the press, would be an advantage.

Freedom of Censure on the Conduct of their Rulers, is necessary for the good of the People.

It is perfectly clear that all chance of advantage to the people, from having the choice of their rulers, depends upon their making a good choice. If they make a bad choice, if they elect people either incapable, or disinclined, to use well the power intrusted to them, they incur the same evils to which they are doomed when they are deprived of the due control over those by whom their affairs are administered.

We may then ask, if there are any possible means by which the people can make a good choice, besides the *liberty of the press?* The very foundation of a good choice is knowledge. The fuller and more perfect the knowledge, the better the chance, where all sinister interest is absent, of a good choice. How can the people receive the most perfect knowledge relative to the characters of those who present themselves to their choice, but by information conveyed freely, and without reserve, from one to another?

There is another use of the freedom of the press, no less deserving the most profound attention, that of making known the conduct of the individuals who have been chosen. This latter service is of so much importance, that upon it the whole value of the former depends.

This is capable of being rigidly demonstrated. No benefit is obtained by making choice of a man who is well qualified to serve the people, and also well inclined to serve them, if you place him in a situation in which he will have preponderant motives to serve himself at their expense.

If any set of men are chosen to wield the powers of government, while the people have not the means of knowing in what manner they discharge their duties, they will have the means of serving themselves at the expense of the people; and all the miseries of evil government are the certain consequence.

Suppose the people to choose the members of the legislative assembly, with power of rechoosing or dismissing them at short intervals; to what desirable end could these powers be exercised, without the liberty of the press? Suppose that any one of those whom they have chosen has misconducted himself, or promoted, as far as depended upon him, the ends of misgovernment, how are the people to know that the powers with which they had intrusted him had been treacherously employed?

If they do not know, they will rechoose him, and that as cordially as the man who has served them with the greatest fidelity. This they are under a deplorable necessity of doing, even to be just; for, as they know no difference between him and the best, it would be on their part iniquity to make any. The consequences would be fatal. If one man saw that he might promote misrule for his own advantage, so would another; so of course would they all. In these circumstances we see laid the foundation on which, in every country, bad government is reared. On this foundation it is impossible that it should not be reared. When the causes are the same, who can expect that the effects will be different? It is unnecessary to dwell upon these fundamental truths, because they have already been developed in the article Government.

Without the knowledge, then, of what is done by their representatives, in the use of the powers intrusted to them, the people cannot profit by the power of choosing them, and the advantages of good government are unattainable. It will not surely cost many words to satisfy all classes of readers, that, without the free and unrestrained use of the press, the requisite knowledge cannot be obtained.

That an accurate report of what is done by each of the representatives, a transcript of his speeches, and a statement of his propositions and votes, is necessary to be laid before the people, to enable them to judge of his conduct, nobody, we presume, will deny. This requires the use of the cheapest means of communication, and, we add, the free use of those means. Unless every man has the liberty of publishing the proceedings of the legislative assembly, the people can have no security that they are fairly published. If it is in the power of their rulers to permit one person, and forbid another, the people may be sure that a false report, that is, a report calculated to make them believe that they are well governed when they are ill governed, will be often presented to them.

Liberty of the Press.

One thing more is necessary, and so necessary, that if it is wanting, the other might as well be wanting also. The publication of the proceedings tells what is done. This, however, is useless, unless a correct judgment is passed upon what is done.

We have brought this inquiry, then, to an important point. In the article Government, we have seen that, unless the people hold in their own hands an effectual power of control on the acts of their government, the government will be inevitably vicious. We have now seen that they cannot exercise this control to any beneficial purpose, without the means of forming a correct judgment upon the conduct of their representatives. We have likewise seen, that one of the means necessary to enable them to judge correctly of the conduct of their representatives, is the liberty to every body of publishing reports of what they do. It remains to inquire by what other acts the press can be made to contribute to the same desirable end.

What is wanted is, that all the people, or as many of them as possible, should estimate correctly the consequences of the acts proposed or done by their representatives, and also that they should know what acts might have been proposed, if the best were not proposed, from which better consequences would have followed. This end would be accomplished most effectually, if those who are sufficiently enlightened would point out to those who are in danger of mistakes, the true conclusions; and, showing the weight of evidence to be in their favour, should obtain for them the universal assent.

How is this to be accomplished? In what manner are those wise men to be chosen? And who are to be the choosers? Directly the object cannot be attained. There are no distinct and indubitable marks by which wisdom, and less by which integrity, is to be known. And who is to be trusted with the privilege of pointing them out? They whose judgment requires to be directed are not well qualified to determine who shall direct them. And if the rulers are to choose, they will employ none but those who will act in conformity to their views, and enable them to benefit themselves by the pillage and oppression of the people.

As there is no possible organ of choice, no choice whatever ought to be made. If no choice is to be made, every man that pleases ought to be allowed. All this is indubitable. The consequences of denying any part of it are so obvious, that hardly any man, we suppose, will risk the imputations to which such a denial would justly expose him.

They who say that no choice ought to be made, say, in effect, that no limit whatsoever ought to be imposed upon the liberty of the press. The one of these propositions is involved in the other. To impose any restraint upon the liberty of the press, is undoubtedly to make a choice. If the restraint is imposed by the government, it is the government that chooses the directors of the public mind. If any government chooses the directors of the public mind, that government is despotic.

Suppose that, by the restraint imposed upon the liberty of the press, all censure of the government is forbidden; here is undoubtedly a choice. The government, in this case, virtually says, the people who might attempt the task of directing the public mind are of two sorts; one, those who would censure; another, those who would not censure; I choose the latter.

Suppose that not every censure, but only such and such kinds of censure, are forbidden; here, again, is still a choice, while confessedly there is no party to whom the power of choosing for the rest can with safety be given.

If not every censure, but only some censures, are to be forbidden, what are those to which the prohibition should extend? The answer to this question will elucidate nearly all that yet remains in any degree obscure, of the doctrine of the liberty of the press.

It will not be said that any censure which is just should be forbidden, because that would undoubtedly be to detract from the means of enabling the people to form correct judgments; and we have, we trust, rendered it indisputable that no source of benefit to society is at all to be compared with that of correct judgments, on their government and its functionaries, formed by the people, and determining their actions.

But what censures are just and what are unjust; in other words, what are the conclusions which ought to be formed respecting the properties and the acts of the government, is exactly the point to be determined. If you say that no man is to pass an unjust censure upon the government, who is to judge? It is surely unnecessary to repeat the proof of the proposition, that there is nobody who can safely be permitted to judge. The path of practical wisdom is as clear as day: all censures must be permitted equally, just and unjust.

Where various conclusions are formed among a number of men, upon a subject on which it would be unsafe, and therefore improper, to give any minor portion of them a power of determining for the rest, only one expedient remains. Fortunately, that is an expedient, the operation of which is powerful, and its effects beneficial in the highest degree. All the conclusions which have formed themselves in the minds of different individuals should be openly adduced, and the power of comparison and choice should be granted to all. Where there is no motive to attach a man to error, it is natural to him to embrace the truth; especially if pains are taken to adapt the explanation to his capacity. Every man possessed of reason is accustomed to weigh evidence, and to be guided and determined by its preponderance. When various conclusions are, with their evidence, presented with equal care and with equal skill, there is a moral certainty, though some few may be misguided, that the greater number will judge right, and that the greatest force of evidence, wherever it is, will produce the greatest impression.

As this is a proposition upon which every thing depends, it is happy that the evidence of it should be so very clear and striking. There is, indeed, hardly any law of human nature more generally recognised, wherever there is not a motive to deny its existence. "To the position of Tully, that if Virtue could be seen, she must be loved, may be added," says Dr Johnson, "that if Truth could be heard, she must be obeyed." (*Rambler*, No. 87.) "Je vous plains, mes Pères," says M. Pascal to the Jesuits, "d'avoir recours à de tels remèdes. Vous croyez avoir la force et l'impunité: mais je crois avoir la vérité, et l'innocence. C'est une étrange et longue guerre que celle où la violence essaie d'opprimer la vérité. Tous les efforts de la violence ne peuvent affoiblir la vérité, et ne servent qu'à la relever davantage: toutes les lumières de la vérité ne peuvent rien pour arrêter la violence, et ne font que l'irriter encore plus. Quand la force combat la force, la plus puissante détruit la moindre: quand l'on expose les discours aux discours, ceux qui sont véritables et convainquants confondent et dissipent ceux qui n'ont que la vanité et le mensonge." (*Lettres Provinciales*, 12.)—"Reason," says Burke, "clearly and manfully delivered, has in itself a mighty force; but reason, in the mouth of legal authority, is, I may fairly say, irresistible." (*Letter on a Regicide Peace.*)

It is of importance to show how many of the greatest men, of all ages and countries, have borne testimony to the prevalence of true over false conclusions, when both are fairly offered to the human mind. "Truth," says Mr Locke, "certainly would do well enough, if she were once left to shift for herself. She seldom has received, and I fear never will receive, much assistance from the power of great men, to whom she is but rarely known, and more rarely welcome. She is not taught by laws, nor has she any need of force to procure her entrance into the minds of men." (*Letter on Toleration.*) The following is the emphatical language of Montesquieu: "La raison a un empire naturel; elle a même un empire tyrannique: on lui resiste, mais cette resistance est son triomphe, encore un peu de temps, et l'on sera forcé de revenir à elle." (*Esprit de Loix*, l. xxviii. ch. 38.) "It is noted out of Cicero, by Machiavel, that the people, though they are not so prone to find out truth of themselves, as to follow custom, or run into error, yet if they be shown truth, they not only acknowledge and embrace it very suddenly, but are the most constant and faithful guardians and conservators of it." (*Harrington.*) "The labour of a confutation," says Chillingworth, "I have not in any place found such labour or difficulty, but that it was undertakeable by a man of very mean abilities; and the reason is, because it is *Truth* I plead for; which is so strong an argument for itself, that it needs only light to discover it." (*Religion of Protestants.*) "About things on which the public thinks long," says Dr Johnson, "it commonly attains to think right." (*Life of Addison.*) "The adversary," says Dr Campbell, "is both subtile and powerful. With such an adversary, I should on very unequal terms enter the lists, had I not the advantage of being on the side of truth. And an eminent advantage this doubtless is. It requires but moderate abilities to speak in defence of a good cause. A good cause demands but a distinct exposition, and a fair hearing; and we may say, with great propriety, it will speak for itself." (Campbell *on Miracles*, Introd.)

We have, then, arrived at the following important conclusions, viz. that there is no safety to the people in allowing any body to choose opinions for them; that there are no marks by which it can be decided beforehand, what opinions are true and what are false; that there must, therefore, be equal freedom of declaring all opinions, both true and false; and that, when all opinions, true and false, are equally declared, the assent of the greater number, when their interests are not opposed to them, may always be expected to be given to the true. These principles, the foundation of which appears to be impregnable, suffice for the speedy determination of every practical question.

All censure thrown upon the government, all censure thrown either upon the institutions of the government, or upon the conduct of any of the functionaries of government, supreme or subordinate, has a tendency to produce resistance to the government.

Of the censures thrown upon government, some may have a tendency to produce resistance to the operations of government in detail; others that general resistance which has in view some great alteration in the government.

Of the first sort would be any such accusation of the conduct and disposition of a judge, as might excite the people, whose sympathies were roused in favour of the individual against whom his sentence was to operate, to rescue him from the officers of justice. We have already shown that such a rescue ought to be punished, and any direct exhortation to it ought to be punished. It will now be evident, we trust, that no censure on the judge, though capable of being treated as an indirect exhortation, ought to be punished.

The reason is conclusive. The people ought to know, if possible, the real qualities of the actions of those who are intrusted with any share in the management of their affairs. This they have no chance of knowing, without the of unlimited power of censure upon those actions, both in gross and detail. To see the full force of these propositions, it is only necessary to apply the principles which have been already established.

If the people have not the means of knowing the actions of all public functionaries, they have no security for the good conduct even of their representatives. Suppose it is the duty of their representatives to watch the conduct of the judges, and secure the perfection of judicature, the people cannot know whether their representatives perform this duty, unless they know what the conduct of the judges is. Ignorance of this would of itself suffice to vitiate the government. A door would be left open, through which the rulers might benefit themselves at the expense of the people. All the profit to be made by an abuse of the power of justice, would thus become the profit of the representatives, by whom it would be allowed and encouraged, as far as the knowledge which they could not withhold from the people would permit.

That the people ought, therefore, to know the conduct of their judges, and when we say judges we mean every other functionary, and the more perfectly the better, may be laid down as indubitable. They are deprived of all trust-worthy means of knowing, if any limit whatsoever is placed to the power of censure.

All censure consists in the delivery of an unfavourable opinion, with or without the grounds of it. This is the essence of censure. But if the conduct of the judge deserves that an unfavourable opinion should be entertained of it, the more perfectly that is known to the people the better.

The conduct of the judge, on this occasion, says a defender, does not deserve an unfavourable opinion. A public expression of such an opinion ought, therefore, to be prohibited. But there are occasions on which the conduct of judges deserves an unfavourable opinion. When it is deserved, there is no security for good government, unless it is allowed to be made known. How can you allow an unfavourable opinion to be delivered in the one case, and not delivered in the other? To have the benefit of it in the one case, you must submit to the evil of it in the other.

In matters of Government, undeserved Praise is as mischievous as undeserved Blame.

As the real point of importance is, to establish correct opinions in the minds of the people, it is as mischievous to inculcate a favourable opinion when an unfavourable is deserved, as an unfavourable when a favourable is deserved; and, in the eye of reason, it is incontrovertible, that, if the one deserves to be prevented by punishment, so does the other.

But if an unfavourable opinion is pronounced of any public functionary—of a judge, for example—would you have it left uncontradicted? Would you not grant the liberty of calling in question the truth of the allegations, and of supporting a different opinion? If not, the character of no public functionary would be safe, and any man, however deserving, might be made to appear the proper object of the most unfavourable sentiments. Why should not the two cases be treated equally? Why should not the favourable, as well as the unfavourable opinion, be open to contradiction.

It is perfectly certain, that it is not in the power of law to mark out, by antecedent definition, any sort of men, of whom it can say, all opinions favourable to such men shall be punished. It can never be affirmed of any men beforehand, that they will certainly perform such and such injurious actions. If they do not perform them, all declarations conformable with the matter of fact are good. But the question is, whether they have performed them? One man affirms that they have. Is that to be taken for granted? And is no man to be allowed to affirm the contrary, and to sift the grounds upon which the allegations of the other man are supported? It is by weighing well the evidence on both sides that a well-founded opinion is capable of being formed. And it is certain, that the best security for having the evidence on both sides fully adduced, and the strength and weakness of it perfectly disclosed, is by permitting all those who are attached to different opinions to do what they can for the support of them.

If it is evident that it ought not to be permitted to speak evil of public functionaries without limit, while any limit is put to the power of speaking well of them; it is equally evident that, for the purpose of forming a correct opinion of their conduct, it ought not to be permitted to speak well of them, and oppose any limit whatsoever to the power of speaking ill of them.

It ought not to be permitted to speak evil of them without an equal liberty of speaking well; because, in that case, the evidence against them might be made to appear much stronger than it was. It ought not to be permitted to speak well of them without an equal liberty of speaking ill; because, in that case, the evidence in favour of them might be made to appear much greater than it really was. In either case, the people would be misguided, and defrauded of that moral knowledge of the conduct of their rulers, the paramount importance of which has so fully appeared.

It may be said (as by the short-sighted, if we did not anticipate them, it would be said), that if, by limiting the power of censure, the people are made to judge more favourably of their rulers than they deserve, the evil is small; but if they are permitted to form a very unfavourable opinion, the consequences are alarming.

We believe it may be rigidly demonstrated, that no evils are greater than those which result from a more favourable opinion of their rulers, on the part of the people, than their rulers deserve; because just as far as that undue favour extends, bad government is secured. By an opinion of their rulers more favourable than they deserve, is implied an ignorance on the part of the people of certain acts of their rulers by which the people suffer. All acts by which the rulers have any motive to make the people suffer, are acts by which the rulers profit. When the ignorance of the people extends to material points, all the evils of bad government are secured. These are the greatest of all possible evils. To this it will not be said that the ignorance of the people ought to extend. On all material points, it is admitted, then, that the freedom of censure ought to be complete. But if it is to be allowed on great points, on those where it is calculated to excite the greatest disapprobation; what can be thought of their consistency, who would restrain it on those where it is only calculated to excite a small? If it is proper to protect the people from great injuries at the hands of their rulers, by exciting a strong, it is good to protect them against small injuries, by exciting a weak disapprobation.

To public functionaries may be imputed either acts which they have not performed, or a want of certain qualifications, moral or intellectual, which they ought to possess.

With respect to acts, and even dispositions, which do not, either directly or indirectly, concern their public function, the same protection may be safely extended to them as to private men.

Acts, in their public capacity, which they have not performed, may be imputed to them either by mere forgery, and without any appearance of ground, or they may be imputed with some appearance of ground. From permitting the former, no good can be derived. They ought, therefore, to be prevented, in the same way as false imputations, injurious to individuals in their private capacity. That there should be no restraint in imputing actions to any public functionary which he may appear to have done, flows immediately from the principles already established, and requires not that any thing should here be added to its proof. Any appearance sufficient to lay the foundation of the slightest suspicion, renders it useful to call the attention of the public to the suspected part, which can only be done by making the suspicion known. A man may, indeed, publish, as a matter of fact, what is supported by appearances which would only justify the slightest suspicion. In that case, he is sure of incurring the disgrace of temerity, if not of malignity; and this is all the penalty which needs or can safely be inflicted upon him.

In imputing inaptitude to a public functionary, on the score either of intellectual or moral qualities, scarcely any limitation would be safe. Every man ought to have liberty to declare upon this subject any opinion which he pleases, and support it by any evidence which he may think adapted to the end. If, in supporting his opinion of the inaptitude of any public functionary, he imputes to him actions which there is not even an appearance of his having performed, that limited prohibition, the propriety of which we have just recognised, will strictly apply. With this exception, freedom should be unimpaired.

We have now, therefore, explained, we hope sufficiently, in what manner the principles which we have established require that the use of the press should be regulated in speaking of the actions of public functionaries, and of their fitness for the duties which they are appointed to discharge, whether those functionaries are the immediate representatives of the people, or others whom it is the business of those representatives to control.

Freedom of Censure on the Institutions of Government is necessary for the good of the People.

We have next to inquire in what manner those principles require that the use of the press should be regulated in speaking of the *institutions* of government. The illustrations already adduced will supersede the use of many words upon this part of the subject.

Institutions of government are good in proportion as they save the people from evil. Institutions of government are bad in proportion as they are the cause of evil to the people, either by what they create, or what they fail in preventing.

According to this statement, which it is impossible to controvert, institutions of government may, in strict propriety of speech, be said to be the cause of all the evil which they do not save the people from, and from which the people would be saved by any other institutions.

It is therefore of the highest importance that the people should know what are the institutions which save from the greatest quantity of evil, and how much their own institutions want of being those best institutions.

Institutions of government are bad, either because those in whose hands the powers of government are placed, do not know that they are bad, and, though willing, cannot improve them; or they are bad, because those who have in their hands the powers of government do not wish that they should be improved.

When the rulers are willing, but do not know how to improve the institutions of government, every thing which leads to a knowledge of their defects is desirable to both rulers and people. That which most certainly leads to such knowledge is, that every man who thinks he understands any thing of the subject, should produce his opinions, with the evidence on which they are supported, and that every man who disapproves of these opinions should state his objections. All the knowledge which all the individuals in the society possess upon the subject is thus brought, as it were, to a common stock or treasury; while every thing which has the appearance of being knowledge, but is only a counterfeit of knowledge, is assayed and rejected. Every subject has the best chance of becoming thoroughly understood, when, by the delivery of all opinions, it is presented in all points of view; when all the evidence upon both sides is brought forward, and all those who are most interested in showing the weakness of what is weak in it, and the strength of what is strong, are, by the freedom of the press, permitted, and by the warmth of discussion excited, to devote to it the keenest application of their faculties. False opinions will then be delivered. True; but when are we most secure against the influence of false opinions? Most assuredly when the grounds of those opinions are the most thoroughly searched. When are the grounds of opinions most thoroughly searched? When discussion upon the subject is the most general and the most intense; when the greatest number of qualified persons engage in the discussion, and are excited by all the warmth of competition, and all the interest of important consequences, to study the subject with the deepest attention. To give a body of rulers, or any other body of men, a power of choosing, for the rest, opinions upon government, without discussion, we have already seen, upon good evidence, is the way to secure the prevalence of the most destructive errors.

When institutions are bad, and the rulers would gladly change them if they knew they were bad, discussion, it will not be disputed, would be good for both parties, rulers and ruled. There is, however, another case, and that by far the most common, where the rulers are attached to the bad institutions, and are disposed to do all in their power to prevent any alteration. This is the case with all institutions which leave it in the power of the men who are intrusted with the powers of government, to make use of them for their own advantage, to the detriment of the people; in other words, which enable them to do injury to the people, or prevent the people from good. This is the case with by far the greater number of those institutions by which the people suffer. They are institutions contrived for benefiting the few at the cost of the many.

With respect, therefore, to the greater number of defective institutions, it is the interest of the rulers that true opinions should not prevail. But with respect to those institutions, it is of still greater importance to the people that discussion should be free. Such institutions as the rulers would improve, if they knew that they were defective, will be improved as the rulers themselves become sensible of their defects. Such defective institutions as the rulers would not wish to see improved, will never be improved, unless the knowledge of those defects is diffused among the people, and excites among them a disapprobation which the rulers do not think it prudent to disregard.

That the prevalence of true opinions among the people, relative to those defects in their political institutions, by which the rulers profit at their expense, is of the utmost importance to the people, is therefore a proposition which no improbity will dare openly to controvert. That freedom of discussion is the only security which the people can have for the prevalence of true opinions, has already been proved. It is therefore proved, that freedom of discussion, in its utmost perfection, they ought to enjoy.

What is included in the term, *freedom of discussion*, is evident from what has already been said.

Freedom of discussion means the power of presenting all opinions equally, relative to the subject of discussion; and of recommending them by any medium of persuasion which the author may think proper to employ. If any obstruction is given to the delivering of one sort of opinions, not given to the delivering of another; if any advantage is attached to the delivering of one sort of opinions, not attached to the delivery of another; so far equality of treatment is destroyed, and so far the freedom of discussion is infringed; so far truth is not left to the support of her own evidence; and so far, if the advantages are attached to the side of error, truth is deprived of her chance of prevailing.

To attach advantage to the delivering of one set of opinions, disadvantage to the delivering of another, is to make a choice. But we have already seen, that it is not safe for the people to let any body choose opinions for them. If it be said, that the people themselves might be the authors of this preference, what is this but to say, that the people can choose better before discussion than after; before they have obtained information than after it? No; if the people choose before discussion, before information, they cannot choose for themselves. They must follow blindly the impulse of certain individuals, who, therefore, choose for them. This is, therefore, a pretence, for the purpose of disguising the truth, and cheating the people of that choice, upon which all their security for good government depends.

If these deductions are as clear and incontrovertible as to us they appear to be, the inquiry respecting the principles which ought to regulate the use of the press is drawn pretty nearly to its close. We have shown that, as far as regards the violation of the rights of individuals, in respect to both persons and things, no definition on account of the press is required. We have shown in what manner the rights of individuals, in regard to reputation, should be defined by the civil code, and the violation of them prevented by the penal. We next proceeded to what may be considered as the main branch of the inquiry, namely, the use of the press in speaking of the institutions and functionaries of government. We have found that, in this respect, the freedom of the press is of such importance, that there is no ecurity for good government without it. We have also found, that the use of it, in respect to those subjects, admits of but two useful restrictions, that of a direct exhortaion to obstruct any of the operations of government in deail, and that of imputing to a functionary of government criminal act, which there was no ground, nor even an appearance of ground, to impute to him. These restrictions, f course, it would be very easy to define in the criminal ode, and to find appropriate motives to sanction. In all ther respects, we have seen that the press ought to be ree; that if there is any limit to the power of delivering nfavourable opinions respecting either the functionaries r the institutions of government, and of recommending hose opinions by any media, with the single exception of alse facts, under the circumstances mentioned above, the enefits which may be derived from the freedom of the ress are so greatly infringed, that hardly any security for ood government can remain.

V.—LIMITATIONS TO FREEDOM OF DISCUSSION, WHICH INVOLVE ITS DESTRUCTION.

In the administration of English law, or rather of what called law, upon this subject, without being any thing etter than the arbitrary will of the judges, it is said, that ough discussion should be free, it should be "decent;" nd that all "indecency" in discussion should be punished a libel. It is not our object in this discourse to give an xposition of the manifold deformities of the English law libel. If we have been successful in developing the true inciples which ought to regulate the freedom of the ess, every reader may, by an application of those princiles, determine what he ought to think of the several parculars which there may attract his attention. We shall confine ourselves to a short notice of those *dicta*, or doctrines, which seem most likely to be pleaded, in opposition to the principles which we have endeavoured to establish.

The question is, whether *indecent* discussion should be prohibited? To answer this question, we must, of course, inquire, what is meant by indecent.

In English libel law, where this term holds so distinguished a place, is it not defined?

English legislators have not hitherto been good at defining; and English lawyers have always vehemently condemned, and grossly abused it. The word "indecent," therefore, has always been a term under which it was not difficult, on each occasion, for the judge to include whatever he did not like. "Decent," and "what the judge likes," have been pretty nearly synonymous.

Indecency of discussion cannot mean the delivery either of true or of false opinions, because discussion implies both. In all discussion there is supposed at least two parties, one who affirms, and one who denies. One of them must be in the wrong.

The delivery, though not of all true opinions, yet of some, may be said to be indecent. All opinions are either favourable or unfavourable. True opinions that are favourable to government and its functionaries will not be said to be indecent; nor will all opinions that are true and unfavourable be marked out for prohibition under that name. Opinions unfavourable may either be greatly unfavourable or slightly unfavourable. If any unfavourable opinions are exempted from the charge of indecency, it must be those which are slightly so. But observe what would be the consequence of prohibiting, as indecent, those which are greatly unfavourable. A true opinion, greatly unfavourable to a functionary, or institution, of government, is an opinion that the functionary, or institution, is greatly hurtful to the people. You would permit the slight evil to be spoken of, and hence removed; you would not permit the great evil to be spoken of.

If no *true* opinion can be regarded as indecent, meaning by indecent, requiring *punishment*, we must inquire if any *false* opinion on matters of government ought to be treated as such. If all false opinions are indecent, all discussion is indecent. All false opinions, therefore, are not indecent. The English libel law does not treat any favourable opinions, how much soever false, as indecent. If all opinions that are false and unfavourable are said to be indecent, who is to judge if they are false? It has been already proved, that the people can confide the power of determining what opinions are true, what are false, to none but themselves. Nothing can resist the following argument. Either the people do know, or they do not know, that an opinion is false: if they do not know, they can permit nobody to judge for them, and must leave discussion its free course: if they do know, all infliction of evil for the delivery of an opinion which then can do no harm, would be purely mischievous and utterly absurd.

If all opinions, true and false, must be allowed to be delivered, so must all the media of proof. We need not examine minutely the truth of this inference, because it will probably be allowed. It will be said, however, that though all opinions may be delivered, and the grounds of them stated, it must be done in calm and gentle language. Vehement expressions, all words and phrases calculated to inflame, may justly be regarded as indecent, because they have a tendency rather to pervert than rectify the judgment.

To examine this proposition, it must be taken out of that state of vagueness in which so many things are left by the English law, and made, if possible, to speak a language, the meaning of which may be ascertained.

We have just decided, and, as it appeared, on very substantial grounds, that the statement of no opinion, favourable or unfavourable, true or false, with its media of proof, ought to be forbidden. No language necessary for that purpose can be indecent, meaning here, as before, nothing by that term, as nothing can be meant, but simply *punishable*, or proper for punishment.

But the only difference between delivering an opinion one way and another way is, that in the one case it is simply delivered, in the other it is delivered with indications of passion. The meaning of the phrase in question then must be, that an opinion must not be delivered with indications of passion.

What! not even a favourable one?

"Oh, yes; a favourable one. Merited *praise* ought to be delivered with warmth."

Here, then, is inequality, and therefore mischief, at once. An opinion, meaning here a true opinion, if it is favourable, you allow, if unfavourable, you do not allow, to be delivered in a certain way. Why? Because in that way, you say, it is calculated to make an undue impression. Opinions favourable, then, you wish to make an undue impression, and by that confess the wickedness of your intention. You desire that the people should think better of the institutions and functionaries of their government than they deserve; in other words, you wish the government to be bad.

If opinions, to what degree soever unfavourable, may be freely and fully delivered, there are two conclusive reasons why the terms in which they are delivered should not be liable to punishment. In the first place, the difference between one mode of delivery and another is of little consequence. In the second place, you cannot forbid the delivery in one set of terms, without giving a power of preventing it in almost all.

First, the difference is of little consequence. If I say barely that such a functionary of government, or such an institution of government, is the cause of great injury and suffering to the people, all that I can do more by any language is, to give intimation, that the conduct of such functionary, or the existence of such institution, excites in me great contempt, or great anger, or great hatred, and ought to excite them in others. But if I put this in the way of a direct proposition, I may do so, because then it will be a naked statement with regard to a matter of fact, and cannot be forbidden, without overthrowing the whole of the doctrine which we have already established.

If, then, I give indication of certain sentiments of mine, and of my opinion of what ought to be the sentiments of others *explicitly*, I ought, you say, to be held innocent; if *implicitly*, guilty. Implicitly, or explicitly, that is the difference, and the whole of the difference. If I say, that such a judge, on such an occasion, took a bribe, and pronounced an unjust decision, which ruined a meritorious man and his family, this is a simple declaration of opinion, and ought not, according to the doctrine already established, to meet with the smallest obstruction. If I also state the matter of fact with regard to myself, that this action has excited in me great compassion for the injured family, and great anger and hatred against the author of their wrongs, this must be fully allowed. I must further be allowed to express freely my opinion, that this action ought to excite similar sentiments in other members of the community, and that the judge ought to receive an appropriate punishment. Much of all this, however, I may say in another manner. I may say it much more shortly by implication. Here, I may cry, is an act for the indignation of mankind. Here is a villain, who, invested with the most sacred of trusts, has prostituted it to the vilest of purposes. Why is he not an object of public execration? Why are not the vials of wrath already poured forth upon his odious head? All this means nothing, but that he has committed the act; that I hate him for it, and commiserate the sufferers; that I think he ought to be punished; and that other people ought to feel as I do. It cannot be pretended, that between these two modes of expression, the difference, in point of real and ultimate effect, can be considerable. For a momentary warmth, the passionate language may have considerable power. The permanent opinion formed of the character of the man, as well as the punishment, which, under a tolerable administration of law, he can sustain, must depend wholly upon the real state of the facts; any peculiarity in the language in which the facts may have been originally announced soon loses its effect. If that language has expressed no more indignation than what was really due, it has done nothing more than what the knowledge of the facts themselves would have done. If it has expressed more indignation than what was due, the knowledge of the facts operates immediately to extinguish it, and, what is more, to excite an unfavourable opinion of him who had thus displayed his intemperance. No evil then is produced, or none but what is very slight and momentary. If there should be a short-lived excess of unfavourable feeling, we have next to consider what is the proper remedy. Punishment should never be applied where the end can be obtained by more desirable means. To desire any excess of unfavourable feeling, all that is necessary is to show the precise state of the facts, and the real amount of the evil which they import. All excess of feeling arises from imputing to the facts a greater efficacy in the way of evil than belongs to them. Correct this opinion, and the remedy is complete.

Secondly, you cannot forbid the use of passionate language, without giving a power of obstructing the use of censorial language altogether. The reason exists in the very nature of language. You cannot speak of moral acts in language which does not imply approbation and disapprobation. All such language may be termed passionate language. How can you point out a line where passionate language begins, dispassionate ends? The effect of words upon the mind depends upon the associations which we have with them. But no two men have the same associations with the same words. A word which may excite strains of emotion in one breast, will excite none in another. A word may appear to one man a passionate word, which does not appear so to another. Suppose the legislature were to say, that all censure, conveyed in passionate language, shall be punished, hardly could the vices of either the functionaries or the institutions of government be spoken of in any language which the judges might not condemn as passionate language, and which they would not have an interest, in league with other functionaries, to prohibit by their condemnation. The evil, therefore, which must of necessity be incurred by a power to punish language to which the name of *passionate* could be applied, would be immense. The evil which is incurred by leaving it exempt from punishment is too insignificant to allow that almost any thing should be risked for preventing it.

Religion, in some of its shapes, has, in most countries, been placed on the footing of an institution of the state. Ought the freedom of the press to be as complete, in regard to this, as we have seen that it ought to be, in regard to all other institutions of the state? If any one says that it ought not, it is incumbent upon him to show wherein the principles, which are applicable to the other institutions, fail in their application to this.

We have seen, that, in regard to all other institutions, it is unsafe for the people to permit any but themselves to choose opinions for them. Nothing can be more certain, than that it is unsafe for them to permit any but themselves to choose for them in religion.

If they part with the power of choosing their own religious opinions, they part with every power. It is well known with what ease religious opinions can be made to embrace every thing upon which the unlimited power of rulers, and the utmost degradation of the people, depend. The doctrine of *passive obedience* and non-resistance was a *religious doctrine*. Permit any man, or any set of men, to say what shall, and what shall not, be religious opinions, you make them despotic immediately. This is so obvious, that it requires neither illustration nor proof.

But if the people here, too, must choose opinions for themselves, discussion must have its course; the same propositions which we have proved to be true in regard to other institutions, are true in regard to this; and no opinion ought to be impeded more than another, by any thing but the adduction of evidence on the opposite side. (A. A. A.)

Liberty, in *Mythology*, was a goddess worshipped both amongst the Greeks and the Romans. Amongst the former she was invoked under the title *Eleutheria;* by the latter she was called *Libertas*, and held in singular veneration. Temples, altars, and statues were erected in honour of this deity; and there was consecrated to her on the Aventine hill by Tiberius Gracchus, a magnificent temple, before which was a spacious court called *atrium libertatis*. The Romans also erected a temple in honour of Liberty, when Julius Cæsar established his supremacy over them, as if their liberty had been secured by an event which proved fatal to its existence. In a medal of Brutus, Liberty is exhibited under the figure of a woman, holding in one hand a cap, the symbol of liberty, and in the other two poniards, with the inscription *idibvs Martiis*.

LIBITINA, in the Roman mythology, the goddess who presided over funerals. This goddess was the same with the *Venus Infera* or *Epithymbia* of the Greeks. She had a temple at Rome, where a certain piece of money was lodged for every person who died, and whose name was recorded in a register called *Libitinæ Ratio*. This practice was established by Servius Tullius, to obtain an account of the annual number of deaths in the city of Rome, and consequently the rate of increase or decrease of its inhabitants.

LIBITINARII, were undertakers whose office it was to take care of funerals, prepare all things necessary upon this solemn occasion, and furnish every article required. They obtained their livelihood by this gloomy business, and kept a number of servants to perform the working part of the profession, such as the *pollinctores*, *vespillones*, and others. The name *Libitinarii* is derived from *Libitina*, the goddess of funerals, in whose temple were sold all things relating to funerals. See Funeral.

LIBNA, in *Ancient Geography*, a sacerdotal city in the tribe of Judah, a place of strength, as appears from Sennacherib's laying siege to it (2 Kings, xix.; Isaiah, xxxvii.). In Jerome's time, it was a village, called *Lobna*, in the territory of Eleutheropolis.

LIBOURNE, an arrondissement of the department of the Gironde, in France, 544 square miles in extent. It comprehends nine cantons, which are divided into 143 communes, and contain 105,400 inhabitants. The capital is the city of the same name, situated on the right bank of the Dordogne, where the water of the river Isle falls into it. It is surrounded with walls and pleasing promenades, and contains 900 houses and 8400 inhabitants, whose chief occupations consist in making woollen goods, porcelain, glass and leather, and collecting salt and wine. Long. 0. 21. W. Lat. 44. 55. N.

LIBRA, or Balance, one of the mechanical powers. See Balance.

Libra, in *Astronomy*, one of the twelve signs of the zodiac, exactly opposite to Aries, and so called because when the sun is in this sign at the autumnal equinox, the days and nights are equal, as if weighed in a balance. The stars in this constellation are, according to Ptolemy 17, to Tycho 10, to Hevelius 20, and to Flamsteed 51.

Libra also denotes the ancient Roman pound, borrowed from the Sicilians, who called it *litra*.

The libra was divided into 12 *unciæ* or ounces, and the ounce into 24 scruples. The divisions of the libra were, the *uncia*, one twelfth; the *sextans*, one sixth; the *quadrans*, one fourth; the *triens*, one third; the *quincunx*, five ounces; the *semis*, six; the *septunx*, seven; the *bes*, eight; the *dodrans*, nine; the *dextrans*, ten; and the *deunx*, eleven; whilst the *as* weighed twelve ounces or one libra.

The Roman libra was used in France for the proportions of their coin till the time of Charlemagne, or perhaps till that of Philip I. in 1093, their sols being so proportioned that 20 of them were equal to the libra. By degrees it became a term of account; and every thing of the value of twenty sols was called a *livre*.

Libra Pensa, in our law books, denotes a pound of money in weight. It was usual in former days not only to tell the money, but to weigh it, because many cities, lords, and bishops, having their mints, coined money, and often very bad money too; for which reason, though the pound consisted of twenty shillings, they always weighed it.

LIBRARII, amongst the ancients, were a sort of copyists who transcribed in beautiful or at least legible characters, what had been written by the *notarii* in notes and abbreviations.

LIBRARIES.

Library, in common language, means either an apartment or edifice destined to contain books placed regularly upon shelves, or the books themselves which are therein disposed and arranged. It is in the latter sense only that the term is employed in the present article. The necessity of preserving, in distinct forms, writings relating to particular subjects, first led to the formation of books; and the convenience of being able to compare different writings on the same subject, or to consult various writings on different subjects, naturally suggested the assemblage of books, any considerable collection of which constitutes a library. Hence in almost all parts of the world where civilization has made any considerable progress, traces may be discovered of the existence of libraries. At the period of the Spanish invasion of South America, for instance, emblems or pictural representations were employed instead of writing, letters being wholly unknown; in Yucatan and Honduras there were books composed of the leaves of trees; and in the kingdom of Mexico the natives had a *library*, histories, and calendars, in which they painted such things as had proper figures by their natural representations, and such as had none, by means of various other characters, so that they expressed in this way whatever they pleased.[1] This may be considered as a library in its earliest stage; for all those which are described as having belonged to the ancients were composed of rolls, which, though different in form from our books, supplied the place of them, and, when collected, constituted a library, even in the modern acceptation of that term.

Origin of libraries.

The origin of libraries is involved in obscurity. According to some, the distinction of having first made collections of writings belongs to the Hebrews; but others ascribe this honour to the Egyptians. Those who support the former opinion contend that the care which the Hebrews bestowed in preserving their sacred books, in which the history and fortunes of their ancestors, as well as their laws, were recorded, became an example to other nations; whilst those who hold the latter opinion maintain that, as the civilization and learning of Egypt were of much higher antiquity than in almost any other country with the history of which we are acquainted, and as the art of writing was known and practised therein from the earliest times, indeed long before knowledge had dawned amongst any other people, so it may be presumed that collections of books first began to be made in that region where the art of writing seems to have been originally invented. This question, however, is not one which it is of importance to discuss. It is sufficient to observe, that, in ancient Egypt, the priests appear, from the earliest times, to have kept records or archives, in a character expressly appropriated for the purpose, and hence called hieratic or sacerdotal; that consequently every sacred college contained a library, composed in part at least of such archives; and that, besides, they had written books, in which were inscribed all the knowledge, whether of science or of art, which had either descended to them from their predecessors, or had been the fruit of their own labour and research.

I.—ANCIENT LIBRARIES.

As the earliest form of the graphic art appears to have consisted in inscribing or engraving characters on stone, metal, wood, or other durable substance, so the first public libraries were composed exclusively of archives deposited in the temples, that the acts relating to history and public law might there be preserved. This will be found to hold true almost universally. Men invariably begin with what is absolutely necessary to their well-being; and it is only after the lapse of a long interval that time and the progress of improvement add the useful to the necessary, and the ornamental to the useful.

Libraries of the Egyptians.

Osymandyas, one of the ancient kings of Egypt,[2] is said to have been the first who founded a library, and established it in a division or compartment of the edifice which has sometimes been called his palace and sometimes his tomb. On the entrance was inscribed the words, Ψυχης Ιατρειον, *Medicine of the Soul;* whilst the sculptures upon the walls represented a judge, with the image of truth suspended from his neck, and many books or rolls lying before him. Such is the account given by Diodorus,[3] who had himself visited Egypt, but who merely mentions the fact, without giving us any information as to its contents. It probably contained works of very remote antiquity, and also the books accounted sacred by the Egyptians, all of which perished amidst the destructive ravages which accompanied and followed the Persian invasion under Cambyses. There was also, according to Eustathius and other ancient writers, a fine library at Memphis, deposited in the temple of Phtha, from which Homer has been accused of having stolen both the Iliad and the Odyssey, and afterwards published them as his own. (See the article HOMER.) From this charge, however, the bard has been vindicated by various writers, and by different arguments.

But the most superb library of Egypt, perhaps of the ancient world, was the one founded by Ptolemy Soter, at Alexandria, and enriched by successive sovereigns of that country. About the year 290 B. C. Ptolemy Soter, a learned prince, founded an academy at Alexandria, called the Museum, where there assembled a society of learned men, who were devoted to the study of philosophy and the sciences; and for their use he formed a collection of books, the number of which has been variously computed, by Epiphanius at 54,000, and by Josephus at 200,000.[4] His son Ptolemy Philadelphus, an equally liberal and enlightened prince, collected great numbers of books in the temple of Serapis, in addition to those accumulated by his father, and at his death left in it about 100,000 volumes. He had agents in every part of Asia and of Greece, commissioned to search out and purchase the rarest and most valuable writings; and amongst those he procured were the works of Aristotle, purchased of Neleus,[5] and the Greek version of the Jewish Scriptures, designated the Septuagint, which was undertaken at the suggestion of Demetrius Phalereus, who first executed the office of librarian to this monarch. The measures adopted by Ptolemy Philadelphus, for augmenting the Alexandrian Library, were pursued by his successor Ptolemy Euergetes, with unscrupulous vigour. He caused all books imported into Egypt by Greeks or other foreigners to be seized and sent to the academy or museum, where they were transcribed by persons employed for the purpose; upon which the copies were delivered to the proprietors, and the originals deposited in the library. He borrowed of the Athenians the works of Sophocles, Euripides, and Æschylus; caused them to be transcribed in the most elegant manner possible; retained the originals for his own library; and returned to the Athenians the copies which had been made of them, with fifteen talents[6] for the exchange. As the museum, where the library was originally founded, stood near the royal palace, in the quarter of the city called Bruchion, the books were at first deposited there; but when this building had been completely occupied with books to the number of 400,000 volumes, a supplemental library was erected within the Serapeion, or temple of Serapis; and the books there placed gradually increased to the amount of 300,000 volumes; thus making, in both libraries, a grand total of 700,000 volumes.

The Alexandrian Library continued in all its splendour until the first Alexandrian war, when, during the plunder of the city, the Bruchion portion of the collection was accidentally destroyed by fire, owing to the recklessness of the auxiliary troops. But the library in the Serapeion still remained, and was augmented by subsequent donations, particularly by that of the Pergamean Library, amounting to 200,000 volumes, presented by Mark Antony to Cleopatra; so that it soon surpassed the former both in the number and in the value of its contents. At length, after various revolutions under the Roman emperors, during which the collection was sometimes plundered and sometimes re-established, it was utterly destroyed by the Saracens, under the orders of the Caliph Omar, when they acquired possession of Alexandria, A. D. 642. Amrou, the victorious general, was himself inclined to spare this inestimable treasury of ancient science and learning; but the ignorant and fanatical caliph, to whom he applied for instructions, ordered it to be destroyed. "If," said he, "these writings of the Greeks agree with the Koran, or book Allah, they are useless, and need not be preserved; if they disagree, they are pernicious, and ought to be destroyed." The sentence of destruction was executed with blind obedience. The volumes of parchment or papyrus were distributed to the four thousand baths of the city; and such was their incredible number, that six months were scarcely sufficient for their combustion.[1]

The ancient Greeks, whose poetry has been to us the primary source of all our profane literature, had as yet no other theology than the system which resulted from observations made on the theory of the different parts of nature, when the Hebrews, in the books of Moses, cited by one of those ancient historians who copied the chronicles,[2] read the account of the creation, and, along with it, a summary of the traditions of fifteen centuries of continuous history. These books composed the first collection of the Hebrews; but subsequently this people, like most others, had their archives. Those which Herod caused to be burned, with the intention of destroying the monuments of the ancient families, appear to have reached as far back as the very origin of the nation.[3] But though he consigned the public records to the flames, those of individuals were beyond his power, and afterwards served to re-establish the history of this subjugated people. There also existed libraries, properly so called, in Judæa. One in particular is supposed to have been attached to, if not kept in, the temple of Jerusalem, and the Hebrew authors speak of "the multitude of books;" an expression which seems to imply that the collection was not confined to the sacred books alone, but included others, relating probably to the laws and institutions of Moses, and the history of the Jewish nation. The books, particularly those of history, had indeed become so numerous, that Judas Maccabeus caused extracts to be made and circulated from those contained in the library of Nehemiah,[4] mentioned in the second book of Esdras, in which also were preserved the writings of the prophets, the compositions of David, the letters of the Hebrew kings, and the records of offerings. As the Jews dwelt alone, and were not reckoned amongst the nations, we know nothing of their early literature, beyond the books which are contained in the Old Testament. It has been supposed, however, that they had some cities celebrated on account of the sciences which were there cultivated. Amongst these may be mentioned the town called by Joshua *Kiriath-sepher*, or the *City of Letters*, which was situated near the confines of the tribe of Juda. In later times, the university or school of Tiberias was not less celebrated. It is probable that this and other academies of the same description were furnished with libraries.[5]

Libraries of the Persians.

Scripture also mentions a library of the kings of Persia, which some suppose to have consisted of the historians of that nation, and of memoirs on the affairs of state, but which appears rather to have been a depository of the laws, charters, and ordinances of the Persian kings. In the Hebrew text it is stated that a search was made "in the house of the *rolls*, where the *treasures* were laid up in Babylon," for a decree issued by Cyrus ordaining a temple to be built at Jerusalem; the ordinance sought for, however, was found, not in Babylon, but at Acmetha, in Media.[6] It appears that "the house of the rolls" was not a library belonging to the Persians, but a collection of the records or archives of the kingdom. There was formerly a considerable library at Susa, the residence of the Persian sovereigns, where Metasthenes consulted the annals of the Persian monarchy, in search of materials for his history. This library is mentioned by Diodorus Siculus; but, like that referred to by Ezra, it seems rather to have been a collection of laws and records, than an assemblage of books on science or learning.

Libraries of the Greeks.

Amongst the Greeks, as amongst other nations, the first libraries consisted merely of archives, deposited, for the sake of preservation, in the temples of the gods. The sacred books, of which mention is made by Dionysius of Halicarnassus, under the denomination of Deltoids, were of this description. Amongst the most ancient people of Greece these archives comprehended also the genealogies of the royal families; the successions of the priesthood, which served to fix historical epochs; and the titles of public property, engraved, according to their importance, on marble and on brass. Tacitus attests the existence of one of these titles, which was dated twelve hundred years before his time, and the authenticity of which was recognised by the senate in the time of Tiberius.[7] Amongst the archives were likewise preserved the ancient chronicles, of which the historians of an epoch anterior to the Peloponnesian war had confined themselves to transcribing the contents, with a rigorous fidelity, without either adding or retrenching any thing, not even the circumstances invented in the fictions of mythology, which criticism soon learned to discriminate and to separate from the actual facts.[8] Of Grecian literature or history we have no authentic information prior to the wars of Thebes and of Troy; and it would therefore be fruitless to seek for any traces of books in that nation before those events. The Lacedæmonians had no books; amongst them writing was considered as a superfluous accomplishment. At Athens, on the contrary, the sciences and literature were diligently cultivated.

Pisistratus the tyrant was the first who established a public library in that city, though Strabo ascribes to Aristotle the honour of having rendered this important ser-

---

[1] Hartwell Horne, *Introd. to the Study of Bibliography*, vol. i. p. vi. et seq. Gibbon (*Decl. and Fall of the Roman Empire*, vol. ix. p. 40) has endeavoured to disprove the positive account given by Abulfaragius, by means of negative arguments. It should be con- idered, however, that the direct and positive statement of an historian of such unquestionable credit as Abulfaragius, cannot be set side by arguments of a negative and hypothetical character. Besides, Gibbon's references to Aulus Gellius, Ammianus Marcelli- ius, and Orosius, are foreign to the purpose; inasmuch as the destruction referred to by these writers is that which took place in he time of Julius Cæsar, after which the library was restored, and continued to flourish, until it was annihilated by the Saracens, in onsequence of the decree of Omar.

Ancient Libraries.

vice to his countrymen. In this library he deposited the works of Homer, which he had collected with great difficulty, and at a very considerable expense; and the Athenians themselves were at great pains to increase the collection. The fortunes of this library were various and singular. It was transported to Persia by Xerxes; brought back by Seleucus Nicator; plundered by Sylla; and at last restored by the Emperor Hadrian. On the invasion of the Roman empire by the Goths (A. D. 260), Greece was ravaged; and in the sack of Athens they had collected all the libraries, and were upon the point of setting fire to this funeral pile of ancient learning, when one of their chiefs interposing, dissuaded them from the design, observing at the same time, that as long as the Greeks were addicted to the study of books, they would never apply themselves to that of arms.

Library of Pergamus.

Next to the Alexandrian Library, that of Pergamus was the most conspicuous, and, according to Plutarch, contained 200,000 volumes. It was founded and successively enriched by the kings of Pergamus called Eumenes, all of whom were zealous promoters of the arts, and to one of whom we are indebted for the invention of parchment (*charta Pergamena*). Attalus surpassed all his predecessors in magnificence, and after their example devoted part of his treasures to the purchase of the principal works or writings of his age. As already noticed, the Pergamean library was presented by Antony to Cleopatra, in order to form the foundation of a new library at Alexandria. Vitruvius makes honourable mention of both these libraries.[1] There were other collections of less magnitude, amongst which has been mentioned that of Tyrannion, a grammarian contemporary with Pompey, which is said to have contained about 30,000 volumes.

Places where manuscripts may be supposed still to exist.

These particulars, scanty as they may no doubt seem, are nevertheless sufficient to show that the libraries of Greece, in ancient times, were both numerous and extensive. But a question of much more immediate interest here presents itself, viz. as to whether any of the treasures with which they were enriched still remain undiscovered, and where these may be supposed most likely to be found. On this subject various conjectures have been formed, particularly in regard to the remains of the ancient Greek historians. It is well known that many manuscripts had been collected at a vast expense in Greece for the library of Buda, which was destroyed by the Turks in the year 1526. In this library Alexander Brassicanus had seen the whole of the *Hyperides* with *scholia*, the works of many of the Greek fathers, and also those of the classical writers. From it issued parts of Polybius and of Diodorus Siculus. A manuscript of Heliodorus, from which was afterwards printed the first edition of the *Æthiopica*, likewise belonged to it, having been found by a soldier, who carried it to Vincentius Obsopæus. Neander, speaking of this collection, says, "Ex media Græcia inæstimandis sumptibus emerat Matthias Corvinus rex."[2]

Constantinople and Athos have contributed the greater number of the manuscripts which are still extant in different parts of Europe. Until a comparatively recent period there were monasteries full of learned men at Byzantium, and every monastery had its library. The Turks, on their conquest of Constantinople, did not indulge in that indiscriminate destruction which has sometimes been imputed to them. Mahommed II. secured the library of the Greek emperors, which his successors preserved until it was destroyed by Amurath IV. At Byzantium, Constantine Lascaris transcribed many of the works which were afterwards conveyed to the Royal Library at Madrid; and in this city were procured those manuscripts which, having been presented to Hurtado de Mendoza by Solyman II., were left by the former to the library of the Escorial. Possevin has given partial catalogues of some of the libraries at Constantinople; and an early traveller, who visited that city in the year 1597, mentions a valuable collection which he had seen there, though without specifying its contents. With respect to Athos, it appears that there were deposited in one library alone, two hundred manuscripts originally obtained from the monasteries upon the mountain; and a great part of those formerly at Moscow had been collected by the monk Arsenius, in Athos, at the suggestion of the patriarch Nicon. Thessaly, Chios, Corfu, Crete, Cyprus, Chalce,[3] Rhodes, and Epidauria, may also be mentioned as places which, at different times, have supplied manuscripts.[4]

Mr Walpole is of opinion, that notwithstanding the acquisitions which have already been made, researches in the Levant should not be intermitted. By these many manuscripts may still, according to him, be rescued from destruction. No care whatever appears to have been taken to preserve them. Dr Covell mentions having seen, in the monasteries of Mount Athos and elsewhere, vast heaps of manuscripts of the Fathers, and other learned authors, all covered over with dust and dirt, many of them rotten and spoiled, and never in any instance placed upon shelves or arranged in good order. Mr Walpole also thinks that an inquiry should be made into the truth of what was stated to Hemsterhusius by some Greeks, viz. that part of the comedies of Menander was still extant. "Application," says he, "might be made to the Greek nobles of the Phanar, many of whom are versed in ancient Greek, and probably the possessors of some valuable manuscripts. Parts of the first book of the *Demonstratio Evangelica* of Eusebius were printed by Fabricius, from a manuscript belonging to Prince Mavrocordato; and a copy of the Greek Orators, now in England, was once the property of a Greek noble." This, however, is, we fear, much too sanguine. It is probable that many Greek manuscripts have experienced the treatment which works of the same sort have met with in other countries. Poggius, whilst at the council of Constance, found a manuscript of Quintilian upon the table of a pickling shop. Masson met with one of Agobardus in the hands of a bookbinder, who was preparing to use it for the back of a book; and one of Asconius was about to be employed for the same purpose. In the roof of a Benedictin monastery, Musculus discovered some of the works of Cicero, and the whole of Ovid. Numbers of manuscripts in Greece are irrecoverably lost, either by design or accident, by the casualties of war or the havoc of revolution; and of those which may hereafter be met with, it can scarcely be supposed that almost any will prove to be of much value, or of any great antiquity.

[3] The island in the Propontis or Sea of Marmora.

[4] If the life of Professor Biornstahl had been prolonged, we should probably have received much valuable information concerning the libraries in the monasteries of Thessaly. He had visited all of them, and had resided many days at Triccala for the express purpose of copying a Greek manuscript belonging to a monastery. But having been attacked by fever at the foot of Mount Olympus, he remained ten days without medical assistance, after which he was taken to Salonica, where he died in July 1779. Since his death, no one appears to have resumed the search which he had so diligently pursued.

Ancient Libraries.

A list of the theological manuscripts in the library of Patmos has been given by Possevin; and another, copied by the Marquis of Sligo, has been published by Mr Walpole. The actual catalogue contains the titles of ninety-two manuscripts, and about 400 printed volumes; but the Greek compiler has not stated any circumstance relating to the manuscripts by which an estimate of their value may be formed. He gives no information concerning the form of the letters or that of the spirits, or upon any of those subjects by which a knowledge of their respective dates might be obtained. But there is one manuscript mentioned in the catalogue, in regard to which it is impossible not to feel more than ordinary curiosity. We allude to a manuscript of Diodorus Siculus, an accurate inspection of which would probably determine whether the hopes which were oftener than once entertained, of recovering the lost books of that historian, were in this instance also to be disappointed.[1] But, without dwelling longer upon particulars, we may observe, that notwithstanding the sanguine expectations entertained by the admirers of ancient learning, very few valuable manuscripts have latterly been discovered; and, with the exception of the fragments of ancient authors, deciphered from palimpsest or rescribed manuscripts, it must be admitted, that those accidentally rescued from destruction have, in general, been either of comparatively modern date or of but little consequence. Neither the inquiries which have been extended to the African states, nor the excavations and researches made at Herculanum and Pompeii, have recovered the lost historians, or indeed brought to light any works of importance.[2] (See the article HERCULANEUM.)

can
ies.

Rome was still in its infancy when the archives of the Etruscans contained a continuous collection of public acts, and particularly an uninterrupted series of births and deaths, that enabled that people to fix the unequal duration of the eight centuries of their previous history, which they reckoned up to about the middle of the sixth century before Christ. The details given by Censorinus in Varro, prove that the Etruscans kept regular registers of births and deaths, from the epoch of their first establishment in Italy, which Larcher refers to the year 1344 before Christ; that, the eighth century thereafter, to which the Etruscan histories were written, must have been the sixth before the Christian era, in which other histories appeared that are no longer extant; and that, during these eight hundred years, the most extended term of human life was nearly the same as at the present day. In the works of Dionysius of Halicarnassus, of Plutarch, and other ancient authors, we also discover scattered glimpses of the history of Italy in the most remote times, and learn that the tribes or races by whom the Etruscans were surrounded had also their historical archives. It may even be supposed that the Romans, in causing their Capitoline marbles to be engraved, followed, amongst others, the example of Præneste; a city much more ancient than Rome, and which had long continued the practice of classifying as well as engraving its municipal records. Such were the sources consulted by several historians who treated of the antiquities of different Italian nations, particularly Zenodotus of Trœzene, who composed a history of the Ombrians.

Roman libraries.

If the ancient Greeks had but few books, the ancient Romans possessed still fewer. Incessantly occupied in military expeditions, defensive wars, and the aggrandisement of their empire, that warlike people had no leisure, and, probably, as little inclination, to cultivate letters. It was not until they had subdued Magna Græcia that they began to emerge out of barbarism, nor until they had accomplished the conquest of Greece itself, that a taste for the arts, sciences, and books was diffused amongst them. They became civilized by frequent contact and familiarity with civilization. The immediate consequence of the conquest of Greece was a more frequent intercourse with the Greeks, at once their subjects and their masters; and in proportion as they became acquainted with the literature and arts of that refined people, the asperity of character and manners which had distinguished this nation of conquerors began to disappear.

Libraries in Rome.

The first library established at Rome was that founded by Paulus Æmilius, B. C. 167. Having subdued Perses, king of Macedonia, he enriched the city of Rome with the library of this conquered monarch, which was subsequently augmented by Sylla.[3] On his return from Asia, where he had successfully terminated the first war against Mithridates, Sylla visited Athens, whence he took with him the library of Apellicon the Teian, in which were the works of Aristotle and Theophrastus. Lucullus, another conqueror of Mithridates, was not less distinguished by his taste for books. The number of volumes in his library was immense; and they were written in the most distinct and elegant manner possible. But the use which he made of his collection was still more honourable to that princely Roman than the acquisition or possession of it. His library was open to all; and the Greeks, who visited Rome, resorted to the galleries and porticos of Lucullus as to the retreat of the Muses, where they spent whole days in conversation on literary subjects. But although both Sylla and Lucullus liberally gave public access to their literary treasures, still their libraries can, in strictness, be considered as only *private* collections. Amongst the various projects which Julius Cæsar had formed for the embellishment of Rome was that of a *public* library, which should contain the largest possible collection of Greek and Latin works; and he had assigned to Varro the duty of selecting and arranging them; but this design was frustrated by the assassination of the dictator, and the establishment of public libraries did not take place until the reign of Augustus.

---

[1] See Mr Walpole's observations on this subject, published in Dr Clarke's *Travels*.

[2] *Mémoires de l'Académie des Inscriptions*, tom. vii.; *Nouveau Traité de Diplomatique par deux Benedictins*; Villoison, *Anecdota Græca*, tom. ii.; Fabricius, *Bibliotheca Græca*, tom. xiv.—A letter written at Patmos on the 28th of February 1832, by Professor Thiersch of Munich, gives some interesting information respecting the library of that celebrated island. "We left Geronta on the 23d February," says he, "and reached this island, after experiencing the fury of a violent storm. The town is situated upon the summit of a mountain in the rear of the harbour, and, rising above it like a citadel, stands the monastery of John the Baptist." After the travellers had dried themselves in a storehouse at the harbour, they proceeded to pay their respects to the Hegumenos of the monastery, and the patriarch of Alexandria, who was upon a visit to his birth-place, Patmos; and Thiersch and his companions met a hearty welcome under the prelate's roof, and were received in the far-famed library of the fraternity of monks, which was their principal inducement to visit the island; but, as far as manuscripts connected with ancient literature were concerned, they found none of striking importance. A codex of Diodorus Siculus, extending from the eleventh to the eighteenth book, contained nothing but what has appeared in print; and the readings, so far as Thiersch had an opportunity of investigating them, were not of much interest. He attached greater value to a manuscript of Paulus Ægineta, which is of the ninth or tenth century, and upon a careful examination of which he expresses a confident opinion, that valuable emendations may in consequence be made on the text of Ægineta's work. The library contains enough in grammatical treatises, glossaries, lexicons, and scholia, to afford employment to a young philologist for six months at least; and it is particularly rich in ancient manuscripts of the Bible, amongst which are a Greek manuscript of the book of Job, another of two of the Gospels with commentaries, a third exhibiting the musical characters of the Greek church, and others containing the works of some of its fathers. As these are considered in the light of sacred relics, none of them have been injured, and they are in a respectable state of preservation. But the heathen manuscripts, on the contrary, lie scattered about and cut to pieces; whilst those on cotton paper, having been severely treated by the moths, were, in the course of the last century, thrown by the monks into the oven which they used for baking their bread; an act of literary sacrilege for which these monastic destroyers deserved to have been themselves baked in their own oven. Three or four, which chance saved from destruction, were purchased by Dr Clarke, and are now safely deposited in the Bodleian Library at Oxford. (*Journal of Education*, vol. pp. 176, 177.)

[3] Such is the statement of Isidorus (*Origines*, l. vi. c. 4), though Plutarch (*in Vit. Æmil.* tom. ii. p. 180, ed. Bryan) expressly says that he reserved for his sons, who were literary men, the books taken from the library of King Perses.

The honour of suggesting these valuable institutions is ascribed by the elder Pliny[1] to Assinus Pollio, who erected a public library in the Court of Liberty on the Aventine Hill. Augustus, amongst other embellishments which he bestowed upon Rome, erected two public libraries, viz. the Octavian and the Palatine.[*] The Octavian Library, which was thus denominated in honour of the emperor's sister, stood in the portico of Octavia; and the charge of it was committed to Melissus, who had been manumitted by Augustus. The Palatine Library was added by Augustus to the temple of Apollo, which he had erected on the site of that part of the Palatine House which had been struck by lightning. There were deposited the corrected books of the Sybils; and, from two ancient inscriptions quoted by Lipsius and Pitiscus, it would seem that it consisted of two distinct collections, one Greek and the other Latin. This library having survived the various revolutions of the Roman empire, existed until the time of Gregory the Great, whose mistaken zeal led him to order all the writings of the ancients to be destroyed.[2] The successors of Augustus, though they did not equally encourage learning, were not altogether neglectful of its interests. Suetonius informs us that Tiberius founded a library in the new temple of Apollo; and we learn from some incidental notices, that he instituted another in his own house, called the Tiberian Library. Vespasian, following the example of his predecessors, established a library in the Temple of Peace, which he erected after the burning of the city by order of Nero; and even Domitian, in the commencement of his reign, restored at great expense the libraries which had been destroyed by the conflagration, collecting copies of books from every quarter, and sending persons to Alexandria to transcribe volumes in that celebrated collection, or to correct copies which had been made elsewhere. Various writers have asserted that there was a library attached to the Temple of the Capitol; but they have not informed us by whom it was founded. Lipsius ascribes it to Domitian, whilst Donatus refers it to the Emperor Hadrian, by whom it was at least enlarged, if not founded, and who probably erected the Tiburtine Library, at Tibur, in the vicinity of Rome.[3] But the most magnificent of all the libraries founded by the sovereigns of imperial Rome was that of the Emperor Ulpius Trajanus, from whom it was denominated the Ulpian Library. It was erected in Trajan's Forum, but afterwards removed to the Viminal Hill, to ornament the baths of Diocletian. In this library were deposited the elephantine books, written upon tablets of ivory, wherein were recorded the transactions of the emperors, the proceedings of the senate and Roman magistrates, and the affairs of the provinces. It has been conjectured that the Ulpian Library consisted of both Greek and Latin works; and some authors affirm that Trajan commanded all the books which could be found in the cities he had conquered to be immediately conveyed to Rome, in order to increase his collection. The library of Domitian having been consumed by lightning, in the reign of Commodus, was not restored until the time of Gordian, who rebuilt the edifice, and founded a new library, adding thereto the collection of books bequeathed to him by Quintus Serenus Samonicus, the physician, amounting, it is said, to no less than 72,000 volumes. Donatus conjectures that this library was deposited in the palace of Pompey.[4]

In addition to the imperial libraries, there were others to which the public had access in the principal cities and colonies of the empire. Pliny mentions a public library which he had founded for the use of his countrymen; and Vopiscus informs us that the Emperor Tacitus caused the historical writings of his illustrious namesake to be deposited in the libraries. The number of calcined volumes, which have been excavated from the ruins of Herculanum and Pompeii would also seem to indicate that collections of books were common in those cities. (See the article HERCULANEUM). But the irruptions of the barbarians who overran and desolated the western empire proved more destructive to the interests of literature than either volcanoes or earthquakes, and soon caused the disappearance of those libraries which, during several centuries, had been multiplied in Italy. The libraries of the East, however, escaped this devastating torrent; and both Alexandria and Constantinople preserved their literary treasures, until the capture of those cities by the Saracens and the Turks, who finally subverted the Roman empire in the East.[5]

When Constantine the Great (A. D. 336) made Byzantium the seat of his empire, he decorated that city with splendid edifices, and called it after his own name. Desirous to make reparation to the Christians for the injuries they had suffered during the reign of his predecessor, he commanded the most diligent search to be made after those books which Diocletian had doomed to destruction; he caused transcripts to be made of such as had escaped the fury of the Pagan persecutor; and, having collected others from various quarters, he formed the whole into a library at Constantinople. On the death of Constantine, however, the number of books in the imperial library was only 6900; but it was successively enlarged by the Emperors Julian and Theodosius the younger, who augmented it to 120,000 volumes. Of these, more than half were burned, in the seventh century, by the command of the Emperor Leo III. who thus sought to destroy all the monuments that might be quoted in proof respecting his opposition to the worship of images. In this library was deposited the only authentic copy of the Council of Nice; and it is also said to have contained the poems of Homer, written in gold letters, together with a magnificent copy of the Four Gospels, bound in plates of gold, enriched with precious stones; all of which were consumed in the conflagration. The convulsions which distracted the lower empire were by no means favourable to the interests of literature. In the eleventh century learning flourished for a short time during the reign of Constantine Porphyrogennetus; and this emperor is said to have employed many learned Greeks in collecting books, and forming a library, the arrangement of which he himself superintended. But the final subversion of the eastern empire, and the capture of Constantinople in 1453, dispersed the literati of Greece over western Europe, and placed the literary remains of that capital at the mercy of the conqueror. The imperial library, however, was preserved by the express command of Mohammed, and continued, it is said, to be kept in some apartments of the Seraglio; but whether it was sacrificed in a fit of devotion by Amurath IV. as is commonly supposed, or whether it was suffered to fall into decay from ignorance and neglect, it is now certain that the library of the Sultan contains only Turkish and Arabic writings, and not one Greek or Latin manuscript of any importance.

[5] Hartwell Horne, *Introduction to the Study of Bibliography*, vol. i. p. xv. et seq.

Upon the whole, it appears that books were abundant, both at Rome and at Constantinople, and that learned men in those cities had at their command greater resources than might at first be supposed. Some idea of the quantity of books accessible to persons of study and research may be formed from the great number of references and citations to be found in the works of some authors, particularly in those of Strabo, Pliny, and some others.

II.—LIBRARIES OF THE MIDDLE AGES.

General epithets and figurative expressions frequently convey a meaning which is calculated to mislead. Hearing constantly of "the dark ages," "the period of intellectual night," and "the season of winter in the history of man," we are apt to imagine that, during the time thus designated, the human mind was utterly palsied, and all learning extinct. But in fact, throughout that period, reason, though misdirected, was not asleep; philosophy was rather bewildered than inert; and learning was immured, but not lost. In no part of that long period which extends from the reign of the Emperor Justinian, when Greek and Roman literature everywhere lay open to the light of day, to the fall of Constantinople and the revival of learning in the fifteenth century, do we entirely lose the traces even of the classic authors, much less of sacred literature; for in each intervening age, and in every quarter of Europe, there were writers whose works, being still extant, afford abundant evidence of their acquaintance with most of the principal authors of more remote times.[1] When the empire of the west sunk under the overwhelming pressure of barbarian invasion, those institutions which had been founded and nurtured in the midst of civilization, were, no doubt, swept away by the torrent which desolated Italy, and spread its ravages over all parts of the empire. But learning, though expelled from her ancient establishments, and forced from her favourite haunts, found a safe asylum in the monasteries, which, amidst all the violence and anarchy that reigned without, remained in undisturbed tranquillity, respected even by the barbarians who had overthrown an empire.

Libraries of the Middle Ages.

It is doubtless true that little comparatively is recorded of the libraries of those ages which intervened between the fall of the Roman empire and the revival of letters in Europe about the middle of the fifteenth century. But, as we shall immediately have occasion to show, every age produced learned and inquisitive men, by whom books were highly prized, and industriously collected. Cassiodorus, minister of Theodore, king of the Goths, retired to a monastery which he had built, and there founded a library for the use of the monks, about the middle of the sixth century. At a later period, Charlemagne, distinguished as a patron of learning, instituted, near Lyons, a library, which, according to the statements of historians, contained books bound in a magnificent manner. After this the monasteries almost exclusively possessed libraries, which were increased by the accessions of centuries; and had the zeal of religious reformation been as little destructive to learning as the invasions of the northern barbarians, numberless monuments of ancient learning which are now irrecoverably lost might have been in the hands of every scholar.

Monasteries; system of transcription pursued therein.

The monastic institutions seemed as if framed for the special purpose of transmitting the remains of ancient literature, sacred and profane, through a period in which, except for so extraordinary a provision, they must inevitably have perished. Though there were considerable diversities in the rules and practices of the different orders of monks, the elements of the monastic life were in all orders and in every country the same; and, generally speaking, wherever there was a monastery there was also a manufacture of books. The transcription of ancient works, the only mode in which, anterior to the invention of printing, they could be multiplied and preserved, was a favourite employment among the inmates of these peaceful retreats; and an opinion of meritoriousness attached to the labour, served to animate the diligence, and to encourage the perseverance, of the labourer.[2] If in some monasteries the monks employed themselves in transcribing nothing but missals, legends, and romances, others enriched their libraries with splendid copies of the works of the fathers of the church, and of the Holy Scriptures; and not a few laboured to reproduce such of the classical authors as they were acquainted with or could obtain access to. This system of transcription, to which alone we are indebted for all that remains of ancient learning, was carried on to an extent of which those who are unacquainted with the history of the middle ages can form no conception. We have already had occasion to advert to the occupation of the inmates of the monastic establishments on Mount Athos, the lofty promontory which stretches from the Macedonian coast far into the Ægean Sea; and we have also noticed the immense number of manuscripts which have at different times issued from these establishments. Many manuscripts still extant prove that the copying of books was likewise practised to a great extent during the middle ages, in the monasteries of the Morea, and in those of Eubœa (Negropont), and of Crete (Candia). The latter island seems indeed to have been a place of refuge for learned men during the disastrous period which preceded the fall of the eastern empire; in its monasteries they found an asylum and the means of subsistence. In Calabria and the kingdom of Naples, fifty religious establishments have been mentioned, from which proceeded a large number of the books afterwards collected in the libraries of Rome, Florence, Venice, and Milan.[3] In the monasteries of western Europe, also, especially in those of the British islands, the same system of transcription was carried on. Books were multiplied, and, by their multiplication, preserved, whilst the knowledge of their contents was extended. In a word, it is mainly to the labours of these establishments, that we are indebted for the remains of the classic authors, and the preservation of the sacred books, which they so carefully transcribed.

---

[1] Taylor, *History of the Transmission of Ancient Books to Modern Times*, pp. 86, 87.

[2] "This book, copied by M. N. for the benefit of his soul, was finished in the year 948; may the Lord think upon him!" Such is the subscription of many of the manuscripts of the middle ages; and to us, we confess, there is something almost affecting in its pious simplicity.

[3] Taylor, *History of the Transmission of Ancient Books*, p. 83.

Libraries of the Middle Ages.

State of knowledge.

Under the impression produced by certain loose modes of speaking in relation to the deep and universal ignorance which is said to have prevailed in Europe during seven centuries, the existence of a large number of manuscripts of the classical authors, executed during those very ages, presents a great apparent difficulty. From what motive, it may be asked, or for whose use, were these works transcribed so frequently as to be found in all parts of Europe on the revival of learning? Was this an employment which ignorance would have selected, or which ignorance could have encouraged and promoted? A rapid survey of those ages of darkness, as they are called, will to some extent furnish a solution of the difficulty, by proving that, during these times of general intellectual lethargy, there were not a few individuals who cultivated letters with ardour, and to whom the preservation of books was a matter of the most lively interest. The names which we are about to mention bear but a small proportion to the total number which might be produced, it being sufficient for our purpose to refer to one or two writers in each century; but brief as our exposition must necessarily be, it will nevertheless serve to show that learning was not then completely abandoned to neglect and oblivion.

Sixth and seventh centuries.

The sixth century abounds with writers in all departments of literature, many of whose works, having descended to modern times, afford evidence of the undiminished diffusion of general learning. Amongst these may be mentioned Procopius, the historian; Agathias, his continuator; Boethius, author of the *Consolation of Philosophy;* Hesychius, the lexicographer; Proclus, a Platonic philosopher; Fulgentius and Cassiodorus, ecclesiastical writers; Priscian, the grammarian; Gildas, an Anglo-Saxon historian; Evagrius Scholasticus, an ecclesiastical historian; Simplicius, the commentator of Aristotle and Epictetus; Ammianus Marcellinus, a critic and historian whose works contain very copious references to ancient literature; and Stephen of Byzantium, a grammarian and geographer. The seventh century produced fewer writers than perhaps any other period of equal extent within the compass of history. The only names deserving to be mentioned are those of Theophylact of Simocatta, who wrote a history of the Emperor Mauritius; and Isidore, an ecclesiastical writer.

Eighth century.

In the latter part of the seventh and beginning of the eighth century flourished the Venerable Bede, whose writings afford a proof of the general diffusion of books of all classes in that age. Bede displays extensive if not profound learning, the whole of which he had acquired from the sources ordinarily accessible to monastic students. He was a poet, a rhetorician, an arithmetician, a chronologist, a geographer, a philosopher, and an historian;[1] he was versed in the profane authors, says Bale, beyond any man of that age, and derived his physics and general learning, not from turbid streams, but from pure fountains, that is, from the principal Greek and Latin authors. Even during his life, and whilst he still continued to write, his works were, by the ordinance of the British bishops, appointed to be read in the churches.[2] Alcuin, a disciple of Bede, contributed much, by his learning, and his influence at the court of Charlemagne,[3] to assist that enlightened prince in his endeavours to effect the restoration of literature. He was skilled in the Latin, Greek, and Hebrew languages; he gave lectures in all the sciences; he founded many public schools; and his works, historical and theological, which are still in part extant, justify the reputation he enjoyed.[4]

Ninth tury.

Raban Maurus, a disciple of Alcuin, taught theology, philosophy, poetry, and rhetoric, at Paris, in the school established there by the Anglo-Saxon monks. According to Trithemius, he was well versed in the Holy Scriptures, and thoroughly learned in profane literature. He enriched the monastery of Fulda, on the Rhine, with a large collection of books; founded a school there; and trained in every branch of learning two hundred and seventy monks belonging to the establishment. He was created archbishop of Mayence in 847, and died in 856. One of the first professors in the university of Oxford was John Scot, a man of considerable acquirements. He afterwards went to France, where he translated some Greek authors into Latin, but so literally that his versions were almost unintelligible. His writings display various learning; but they were condemned as heretical by the church, on account of his opinions relative to the eucharist. Being forced to leave France, he took refuge in an English monastery, which, however, afforded him no asylum. At the instigation of the monks, he was, like Cassianus, killed by his scholars, with their iron styles. Contemporary with Scot was Photius, with whom no author of that, or of several succeeding ages, can be compared. Educated for secular employments, and for some time engaged in the service of Michael III., he was by that emperor forcibly invested with the dignity of patriarch of Constantinople (856), in the room of Ignatius; and, that he might pass regularly to this office, he was made monk, reader, sub-deacon, deacon, priest, and patriarch, all in the course of six days. From the office thus violently thrust upon him he was expelled by Basilius, the successor of Michael; but, at the head of a band of soldiers, he repossessed himself of the patriarchate, of which, however, he was at length finally deprived, by similar means, and upon this retired to a monastery, where he ended his days. Before his elevation he had composed the *Myriobiblion,* which, in the form of criticisms, analyses, and extracts, contains accounts of more than two hundred and seventy works, exhibits numerous valuable fragments from authors whose works have perished, and affords important aid in ascertaining the genuineness of many remains of ancient literature.

Tenth tury.

Though of the existing manuscripts so large a number were executed in the tenth century, as to prove that, in the reproduction of books, great activity prevailed in that age, yet it presents the names of but few authors whose works have descended to modern times. Eutychius, patriarch of Alexandria, wrote an universal history which is still extant, and, though crowded with fabulous narratives, displays considerable learning.

Eleven centur

The eleventh century is much richer in distinguished names. Avicenna, an Arabian physician, reduced the science of medicine to a systematic form, including almost every thing that had been written on the subject by his predecessors, and was, besides, well versed in Greek literature. Michael Psellus, a Greek physician, wrote upon subjects of all kinds, and was celebrated for the extent of his acquirements both in sacred and in profane

---

[1] Sixtus Sennensis, a learned Italian of the sixteenth century, quoted by Blount, in his *Censura Celebriorum Authorum.*

[2] When it is remembered that Bede passed his life in a remote monastery (St Peter and St Paul, on the Tyne, in the diocese of Durham), his various learning is at least a proof that the means of acquiring it were within his reach.

[3] Charlemagne laboured zealously to restore learning both in the church and out of it. He invited learned men to his court, employed them in making Latin translations of the Greek classics and the Fathers; founded public schools; and introduced regulations for making a certain degree of education indispensable to all who held office in the church. Muratori, speaking of the exertions of this prince, is also loud in praise of Great Britain and Ireland, "which, in the study of the liberal arts," says he, "surpassed all other nations of the West in those times." "Nor," he adds, "must we omit to record the diligence of the monks of those countries, who raised and maintained the glory of letters which everywhere else was languishing or fallen."

[4] Alcuin, in his letters, quotes familiarly Virgil, Ovid, and Horace.

Libraries of the Middle Ages.

learning. Lanfranco, an Italian, created archbishop of Canterbury by William the Norman, promoted learning amongst the clergy, and was esteemed accomplished in the literature of his age. Anselm, the disciple and successor of Lanfranco, was also in repute for general learning. The works of Suidas, like those of Photius, contain a treasure of various learning upon points of criticism and literary history; whilst his lexicon, besides the definitions of words, includes accounts of ancient authors, and quotations from works which have since perished. Sigibert, a monk of Brabant, has left a chronicle of events from the year 381 to his own time, and a work containing lives of illustrious men; he was, besides, profoundly versed in the Scriptures, and inferior to none of his countrymen in general learning.

The name of Anna Comnena distinguishes the early portion of the twelfth century. She wrote a history of the reign of her father, the Emperor Alexius Comnenus; a work which displays a masculine understanding, and an extensive acquaintance with literature and the sciences. During this century England produced several eminent writers, particularly William of Malmesbury, Geoffrey of Monmouth, Joseph of Exeter,[1] and, somewhat later, Langton, archbishop of Canterbury, esteemed the most learned man of western Europe in those times. Eustathius, archbishop of Thessalonica, flourished towards the close of the twelfth century. His commentaries on Homer, besides serving to elucidate the Greek language by important criticisms, contain innumerable references to the Greek classics, and thus furnish the means of ascertaining the integrity and genuineness of the text of those authors, as it has descended to our times. John and Isaac Tzetzes, critics and grammarians of Constantinople, are still consulted as commentators upon some of the Greek authors.

Robert Grostest, or Greathead, bishop of Lincoln, was celebrated for his skill in the Latin, Greek, and Hebrew languages, as well as for the bold resistance he offered to the exactions of the supreme pontiff.[2] Matthew Paris, the English historian, displays in his works an acquaintance with ancient learning, and a familiar knowledge of the antiquities of his native country. He vigorously opposed the papal usurpations in England; and his reputation for learning and virtue enabled him to effect a considerable reformation in many of the English monasteries. He died in the year 1259. The works of Albert, surnamed the Great, a Dominican friar, and afterwards (in 1260) bishop of Ratisbon, fill twenty-one volumes, forming a sort of encyclopædia of the learning and science of the age. Like Roger Bacon, Albert of Ratisbon incurred amongst his contemporaries the suspicion of dealing in magic. Learning, in the more restricted sense of the term, that is, the knowledge of books, was too common to excite wonder or envy; but science, or a knowledge of nature, acquired by experimental investigation, was so rare, that it seldom failed to engender both, and to occasion perilous accusations of a correspondence with infernal agents.

The revival of learning is usually reckoned to have commenced in the fifteenth century; but even in the fourteenth a decided advancement in almost every department of literature is discernible. Gross and degrading ignorance was wearing away from the bulk of the community in several parts of Europe; the educated classes were acquiring a better taste and more expanded views; and a general awakening of the energies of the human mind was perceptible. This needs no other evidence than is afforded by the works of Dante, Petrarch, Boccacio, Chaucer, and Gower, which were not merely produced in that period, but extensively read and admired. During no part of that long tract of time which extends from the decline of learning in the sixth century till its revival in the fifteenth, had there been a total extinction of the knowledge of ancient literature; and those inestimable treasures which the religious houses had saved from the ravages of revolution, anarchy, and barbarism, now began to be drawn forth and studied. The continuance of the eastern empire till the middle of the fifteenth century, afforded an uninterrupted protection to Greek learning during those periods when western Europe was laid waste by the Gothic nations; and hence, on the revival of letters, the study of the Greek authors first engaged the attention of those individuals whom an awakening impulse now directed to the cultivation of learning. But that of the kindred authors of Rome soon followed; and the monuments of ancient wisdom and genius which had been preserved in the monasteries, furnished ample materials for laying the foundations of a new and more extensive, if not more perfect, edifice of civilization.

Revival of learning.

More than half a century before the taking of Constantinople by the Turks, the learned men of the imperial city, apprehending the approaching ruin of the empire, began to emigrate into Italy, where they opened schools, and became the preceptors of princes, as well as the guides of the public taste, which they directed towards the study of the classical writers of Greece and Rome. The fall of Constantinople, in 1453, filled the Italian cities with these learned strangers. At this period the Italians required only to receive some kind of direction, and to be provided with the means of study. They had for some time been placed in those peculiar circumstances which have almost always proved favourable to the advancement of the human mind. A number of independent states were crowded upon a narrow space, throughout which the same language, diversified by dialects, prevailed, exhibiting, in a sort of reflected or secondary form, that of ancient Italy. The energy, rivalry, and munificence which accompany commerce, kept the whole mass of society in movement; whilst the influence of a religion, which seeks to recommend itself by every embellishment that the genius of man can devise or execute, overruled the debasing tendency of successful trade, and directed the ambition of princely merchants towards objects more refined and intellectual than those which wealth usually selects as the means of distinction.

Formation of libraries.

The formation of libraries, suggested or favoured by the importation of manuscripts from Constantinople, proved the means not only of making more widely known the works of the Greek authors (which had never fallen into oblivion), but of prompting those researches which issued in the recovery of the Latin writers, many of whom had long been forgotten. The appetite for books being thus revived and quickened, neither labour nor expense was spared in accumulating them; learned men were despatched in all directions throughout Europe, Western Asia, and Africa, to collect manuscripts; and, in the course of a few years, most of the authors now known were brought together in the libraries of Rome, Naples, Venice, Florence, Vienna, and Paris. Aided by the munificence of princes and popes, the scholars of the fifteenth century applied themselves to the discovery, restoration, and publication of the remains of Greek and Roman literature; and, in the course of sixty or eighty years, most of the works now known were committed to the press. Since that time additional discoveries have been made; but the principal improvements of a subsequent date have consisted in the emendation of the text of ancient authors, partly by a more extensive collation of manuscripts than the first editors possessed the means of instituting, and partly also by the lights and aids of a cautious and judicious criticism.[1]

---

[1] Author of two Latin poems, one on the Trojan war, and another on the war of Antioch, or the Crusade.

[2] Camden says of Greathead, " he was versed in the languages, and in general literature, in a degree scarcely credible, when the age in which he lived is considered; a terrible reprover of the pope, the adviser of his king [Henry III.], and a lover of truth."

Invention of printing.

The invention of printing, by virtually exempting books from the operation of the law which subjects all human things to decay, has also greatly promoted the process of their renovation. By giving to the issue of an edition of a standard work a degree of importance several hundred times greater than that which belonged to the transcription of a single copy, it has called for a proportionally larger amount of learning, diligence, and caution, in the work of revision; and, by enabling each successive editor to avail himself of the labours of his predecessors, all the advantages resulting from the concentration of many minds upon the same subject have further been secured. Since the fifteenth century, therefore, the lapse of time, instead of gradually impairing and corrupting the literary remains of antiquity, has incessantly contributed to their renovation; what was then unknown or doubtful, imperfect or corrupted, has been ascertained, restored, and completed; and the learning and industry of the four centuries which have since elapsed, being constantly directed towards the same object, have left but few questions of literary antiquity open to controversy. Books are no longer liable to the hazard of extinction from political changes or the decline of learning in this or that country. Unless an universal devastation should overtake every region of the civilized world, the body of learning and science now extant can neither perish nor suffer corruption. And thus it is that the written records of distant ages, as well as the products of modern genius, industry, and research, are secured from extinction by a mode of conservation less liable to extensive hazard than any other that can be imagined.[2]

III.—MODERN LIBRARIES.

Louis Jacob, a Carmelite who wrote on the subject of libraries about the middle of the seventeenth century, enumerates above eleven hundred collections of books, ancient and modern.[3] Many of these were no doubt contained in monasteries, which have since been suppressed, and others did not perhaps possess sufficient consequence to merit specification; but still the numerical amount of them must satisfy the reader as to the impracticability of attempting to comprise, in an article like the present, a complete list, much less a detailed description, of such collections. All that we propose, therefore, under this head, is to extract from the materials before us such particulars as, when thrown together in a condensed form, may serve to convey an accurate idea of the general character, contents, and classification of the principal modern libraries of Europe; and, with this view, as well as for convenient reference, we shall arrange them under their respective heads of *British Libraries*, and *Foreign Libraries*.

British Libraries.

The principal libraries in Great Britain are those of the British Museum and other institutions in London, Lambeth, Oxford, Cambridge, and Althorp, in England; the Advocates', Writers', and College Libraries, Edinburgh, and those of the universities of St Andrews, Glasgow, and Aberdeen, in Scotland; and, lastly, that of Trinity College, in the capital of Ireland.

Library the Britis Museum.

The library of the British Museum, which is now considered as the great national depository of science, literature, art, and antiquities, has been composed of various collections successively obtained, and is chiefly remarkable for its numerous and valuable manuscript acquisitions.

The *department of printed books* consisted originally of the libraries of Sir Hans Sloane and Major Edwards, which were acquired about the middle of last century. In 1757, George II., by an instrument under the great seal, added the library of the kings of England, the printed books of which had been collected from the time of Henry VII., and the manuscripts from a much earlier date. This collection was very rich in the prevailing literature of different periods; and it included, amongst others, the libraries of Archbishop Cranmer, of Henry prince of Wales, and of Isaac Casaubon. His majesty annexed to his gift the privilege which the royal library had acquired in the reign of Queen Anne, of being supplied with a copy of every publication entered at Stationers' Hall. The same department was further enriched, in 1763, by a donation from George III. of a collection of pamphlets and periodical papers published in England between 1640 and 1660, and chiefly illustrative of the civil wars in the time of Charles I., by whom the collection was commenced.

It would be vain to attempt a detailed enumeration of all the additions which have since been made, whether by gift or by purchase. Amongst the smaller acquisitions may be mentioned Dr Thomas Birch's library; two collections of books on musical science from Sir John Hawkins, and one from Dr Charles Burney; Garrick's collection of old English plays; numerous classics from the library of Mr Thomas Tyrwhitt, with his manuscript notes; Sir William Musgrave's collection of biography; a collection of classics, enriched with Dr Bentley's manuscript notes; a library of ceremonials, processions, and heraldry, from Mrs Sophia Sarah Banks; and a collection of Italian history and topography, from Sir Richard Colt Hoare. Amongst the larger and more important are, the general library collected by the Rev. Clayton Mordaunt Cracherode; the law library of Mr Francis Hargrave; the library of science which belonged to the Baron de Moll of Munich; the libraries of M. Guinguené, author of the *Histoire Littéraire d'Italie*, and of the Rev. Dr Charles Burney; and Sir Joseph Banks's library of natural history. Four separate collections of tracts, illustrative of the revolutionary history of France, have been purchased at different times by the trustees, in the exercise of the powers with which they are invested. One of these was the collection formed by the last president of the parliament of Bretagne, at the commencement of the revolution; two others extended generally throughout the whole revolutionary period; and the fourth consisted of a collection of tracts published during the reign of the hundred days in 1815; forming altogether a body of materials for the history of the revolution as complete in regard to France as the collection of pamphlets and tracts already mentioned is with respect to that of the civil wars of England in the time of Charles I. Another feature of the Museum Library is its progressive collection of newspapers from the appearance of the first of these publications in 1588. Sir Hans Sloane had formed a great collection for his day. But to this was added, in 1818, the Burney collection, purchased at the estimated value of L.1000; and since that period the commissioners of stamps have continued periodically to forward to the Museum, copies of all newspapers deposited by the publishers in their office.

---

[1] Taylor, *Hist. of the Transm. of Ancient Books*, p. 106. "This restoration," continues Mr Taylor, "of the remains of ancient works to their pristine integrity, has not been effected like that of a dilapidated building or mutilated statue, by the addition of new materials in an imagined conformity with the plan and taste of the original work, but by the industrious collection and replacement of the very particles of which it first consisted."

[2] Taylor, *History of the Transm. of Ancient Books*, p. 108.

[3] See *Traité des plus belles Bibliothèques*, passim.

In 1823, the Royal Library collected by George III. was presented to the British nation by his successor, George IV., and ordered by parliament to be added to the library of the British Museum, but to be kept for ever separate from the other books in that institution. The general plan of its formation appears to have been determined on by George III. soon after his accession to the throne; and the first extensive purchase made for it was that of the library of Mr Joseph Smith, British consul at Venice, in 1762, for which his majesty paid about L.10,000. In 1768, Mr (afterwards Sir Frederick) Barnard, the librarian, was despatched to the Continent by his majesty; and, as the Jesuits' houses were then being suppressed, and their libraries sold, throughout Europe, he was enabled to purchase, upon the most advantageous terms, a great number of valuable books, including some very remarkable rarities,[1] in France, in Italy, and in Germany. Under the judicious directions of Mr Barnard, the entire collection was formed and arranged; it was fed, during a period of sixty years, by an annual expenditure of about L.2000; and it is in itself perhaps one of the most complete libraries of its extent that was ever formed. It contains selections of the rarest kind, particularly of scarce books which appeared in the first ages of the art of printing; it is rich in early editions of the classics, in books from the press of Caxton, in English history, and in Italian, French, and Spanish literature; and there is likewise a very extensive collection of geography and topography, and of the transactions of learned academies. The number of books in this library is 65,250,[2] exclusively of a very numerous assortment of pamphlets; and it appears to have cost, in direct outlay, about L.130,000, but is estimated as worth at least L.200,000.[3] When the King's Library was added to that which previously belonged to the Museum, the number of duplicate volumes in the two collections was found to be about 21,000 volumes, of which the committee of the House of Commons recommended that not more than 12,000 should be disposed of; and hence, by the gift of George IV., a clear addition was made to the national library of between 40,000 and 50,000 volumes.

The aggregate of the collections here enumerated, augmented annually by gifts, by claims under the copyright acts, and by grants of money from parliament, have now placed the department of printed books in the British Museum upon a respectable footing; though, in point of extent at least, it is still far inferior to the principal libraries of the Continent, particularly those of Berlin, Göttingen, Dresden, Naples, Vienna, Copenhagen, St Petersburg, Munich, and Paris.[4] The number of printed volumes in the library, officially returned to parliament, is 220,000, not 240,000, as stated by Sir Henry Ellis, in his evidence;[5] and nearly L.2000 is expended annually in the purchase of old and of foreign publications. In the department of recent continental literature, numerous deficiencies have been pointed out by Mr Edwards, especially in German literature, in French history, in philosophy and legislation, and in the belles-lettres;[6] deficiencies which, it is to be hoped, will ere long be supplied. According to Sir Henry Ellis, however, "the Museum Library is not decidedly poor in any class."

The nucleus of the *department of manuscripts*, at the establishment of the British Museum, was formed by the Harleian, the Sloane, and the Cottonian collections. The next addition made to this department was that of the manuscripts of the ancient royal library of England, conferred by George II. in 1757. In this last collection, which contains the acquisitions of our kings from the time of Richard II. to the date of the grant by George II., there are a number of valuable manuscripts. Of these, one of the most remarkable is the *Codex Alexandrinus*, a present from Cyril, patriarch of Constantinople, to King Charles I. It is in four quarto volumes, written upon fine vellum, probably between the fourth and sixth centuries, and is believed to be the most ancient manuscript of the Greek Bible now extant, in uncial characters. Many of the other manuscripts came into the royal collection at the time when the monastic institutions of Britain were destroyed; and some of them still retain upon their spare leaves the honest and hearty anathemas which the donors denounced against those who should alienate or remove the respective volumes from the places in which they had been originally deposited. This collection abounds in old scholastic divinity, and possesses many volumes, embellished by the most expert illuminators of different countries, in a succession of periods down to the sixteenth century. In it are also preserved an assemblage of the domestic music-books of Henry VIII., and the Basilicon Doron of James I. in his own handwriting. The *Cottonian* collection, which was purchased for the use of the public in 1701, and annexed by statute to the British Museum in 1753, is especially rich in historical documents

---

[1] Amongst these may be mentioned the Florence Homer of 1488, which formerly brought L.120, but was purchased by Sir Frederick Barnard for 10s.

[2] Sir Henry Ellis, in his evidence before the Select Committee on the British Museum (*Minutes*, 500), states the number loosely at 75,000 volumes; but, in this estimate, every tract in the library is probably considered as a separate volume.

[3] Report of the Select Committee of the House of Commons on the Royal Library, 18th April 1823.

[4] So far from it being true, as stated by Sir Henry Ellis, that "there are few libraries abroad which equal the Museum Library in extent," Mr Edwards has shown (*Letter to Benjamin Hawes, Esq. M.P.* p. 34, et seq.) that there are at least nine which exceed it, some of them greatly; and several others of nearly equal extent, as those of Wolfenbuttel (190,000), Stuttgard (197,000), Madrid (200,000), &c. The extent respectively of the nine libraries which exceed that of the British Museum is thus stated by Mr Edwards:—

	Vols. of Printed Books.	Vols. of MSS.	Population.
Berlin	250,000	5,000	248,816
Göttingen	300,000	5,000	9,594
Dresden	300,000	2,700	69,000
Naples	300,000	6,000	354,000
Vienna	350,000	16,000	320,000
Copenhagen	400,000	20,000	109,000
St Petersburg	400,000	16,000	320,000
Munich	500,000	16,000	95,718
Paris	700,000	80,000	1,528,301
London, British Museum	220,000	22,500	

Nor is the extent of some of these great libraries their only recommendation; what they possess being well selected, and admirably arranged. (See Russell's *Tour in Germany*, vol. i. p. 252, Edinb. 1828.)

[5] Report, *Minutes of Evidence*, 2419.

[6] See his *Letter to Benjamin Hawes, Esq. M.P.*, containing "Strictures on the *Minutes of Evidence* taken before the Select Committee on the British Museum," pp. 19, 20, 21, 22, 23.

from the time of the Saxons to that of James I. It likewise contains the numerous registers of English monasteries; the charters of Edgar and of Henry I. to Hyde Abbey, near Winchester, written in gold letters; and the manuscript called the *Durham Book*, being a copy of the Latin Gospels, with an interlinear Saxon gloss, written about the year 800, illuminated in the most elaborate style of the Anglo-Saxons, and believed to have once belonged to the Venerable Bede. This collection is also rich in royal and other original letters, and comprises the correspondence of most of the great personages, not only of this country, but throughout Europe, from the earliest periods at which letters were written until the commencement of the seventeenth century. The *Harleian* collection is still more miscellaneous, though historical literature in all its branches forms one of its principal features. It is particularly rich in heraldic and genealogical manuscripts, in the visitations of counties, and in English topographical collections; in parliamentary and legal proceedings; in originals, copies, and calendars of ancient records; in abbey registers; in manuscripts of the classics, amongst which is one of the earliest known of the Odyssey of Homer; in missals, antiphonars, and other service-books of the Catholic church; and in ancient English poetry. It possesses two very early copies of the Latin Gospels, written in gold letters; and also contains a large number of splendidly illuminated manuscripts, besides an extensive mass of correspondence. It further includes about three hundred manuscript bibles or biblical books, in Hebrew, Chaldaic, Greek, Arabic, and Latin; nearly two hundred volumes of writings of the fathers of the church; and works on the arts and sciences, amongst which is a tract on the steam-engine, with plans, diagrams, and calculations by Sir Samuel Morland. The *Sloane* collection consists principally of manuscripts on natural history, voyages and travels, on the arts, and especially on medicine. It comprises the chief of Kæmpfer's manuscripts, with the voluminous medical collections of Mayerne, including the annals of his practice at the court of England from 1611 to 1649; and it also contains a collection of medical and other scientific correspondence, with numerous manuscripts on history, poetry, and miscellaneous subjects. Some of the drawings of animals in this collection are exceedingly rich and accurate; two volumes upon vellum are from the pencil of Madame Merian; and one relates entirely to the insects of Surinam.

In 1807, the collection of manuscripts formed by the first Marquis of Lansdowne was added to these libraries, having been purchased by parliament for L.4925. It consists in part of the Burghley and Cæsar papers, supplementary to the Cottonian collection, but principally of a large assemblage of Bishop Kennett's manuscripts, and numerous collections of an historical kind.[1] Another large collection of manuscripts, almost exclusively belonging to the faculty of the law, was purchased in 1813, of the representatives of Mr Francis Hargrave. Amongst these, besides numerous copies of early reports, is an abridgment of equity in forty-three volumes, by Sir Thomas Sewell, master of the rolls. A collection of manuscripts, chiefly of the Greek and Latin classics, which had been formed at a vast expense by the Rev. Dr Charles Burney, was purchased in 1818. Amongst these is the Townley Homer, a manuscript of the Iliad, similar to that of the Odyssey in the Harleian collection;[2] two early manuscripts of the Greek rhetoricians; a volume of the mathematical tracts of Pappus; and a Greek manuscript of Ptolemy's Geography, adorned with maps of the fifteenth century. Two oriental collections have also been added. One of these, made by Mr C. J. Rich whilst British consul at Bagdad, and purchased by parliament in 1825, contains, amongst other rare manuscripts, several copies of the Syriac version of the Scriptures, which are believed to be of great antiquity. The other, a collection made in different countries of the East, and consisting chiefly of Arabic and Persian manuscripts, was bequeathed to the Museum in the year 1827, by the collector, Mr J. F. Hull. In 1829, a small but valuable collection of manuscripts, partly relating to French history, and partly of a literary character, was bequeathed to the Museum by the Earl of Bridgewater, accompanied by a small real estate, and a sum of L.7000 to be invested, and the interests, as they became available, applied in the purchase of manuscripts. The last distinct collection is that of the Howard-Arundel manuscripts, acquired from the Royal Society in 1831, partly by exchange, and partly by purchase at an estimated value of L.3560. It consists of more than five hundred volumes, contains many manuscripts of interest in almost every branch of learning, and is rich in materials for the history of our own country and language. The ancient rolls and charters of the Museum, many thousands in number, form another division of the department of manuscripts, with a distinct catalogue. These records and deeds partly belong to the Cottonian, Harleian, and Sloane collections, and partly are accumulated additions, being chiefly illustrative of English history, and of monastic and other property.

These are the larger and separate collections. The Donation Manuscripts, as they are called, consist of smaller collections, which have either been acquired by purchase or are the gifts or bequests of individuals. Amongst these may be specified, Madox's collections for the history of the Exchequer; Rymer's materials for his *Fœdera*, used and unused; Dr Birch's historical and biographical manuscripts; the decisions of the judges upon claims made in the city of London after the great fire of 1666; Sir William Musgrave's obituary; Cole's collections for a history of Cambridge and Cambridgeshire, with materials for an *Athenæ Cantabrigienses;* various Coptic and other ancient manuscripts taken from the French in Egypt; Ducarel's abstracts of the archiepiscopal registers at Lambeth; a long series of calendars of the Originalia Rolls from 1 Henry VIII. to 2 James I.; Sir Andrew Mitchell's diplomatic correspondence with every part of Europe, during his residence at the court of Frederick the Great of Prussia; Sir William Burrell's and Mr William Hayley's joint collections for the history of Sussex; Mrs Banks's manuscripts on heraldry, processions, and archery; Abbot's drawings and descriptions of American insects, in seventeen vols. quarto; Wollay's collections for Derbyshire; Sir Joseph Banks's foreign correspondence; Essex's and Kerrich's collections on Gothic architecture and costumes; the Stepney papers; the papers of the Count de Puisaye, chiefly relating to the Chouan war and the Royalists of La Vendée, from 1793 to 1825, in a hundred and seventeen vols.; the Jermyn collections for a history of Suffolk, in forty-one vols. folio; the materials collected by Archdeacon Coxe, whilst employed in the compilation of his various historical and other works, in two hundred and six vols.; numerous manuscripts, illustrative of Italian history, selected from the collection of the Earl of Guilford; three hundred and ten rolls commonly known as the Chancellor's Rolls, being duplicates of the great rolls of the Pipe, between 9 Henry II. and 17 James I.; the topographical collections of Samuel, and Daniel Lysons, being chiefly materials for the *Magna Britannia* and "Environs of London;" Egyptian Papyri, partly purchased from Mr Salt and others, and partly presented by Mr J. G. Wilkinson; an extensive collection of ancient Irish manuscripts, including one or two copies of the Brehon Laws; and a selection, made at an expense of more than L.2000, from the manuscripts possessed by Mr Richard Heber. The total number of manuscripts in the Museum is about 25,000.[1]

---

[1] Amongst the single volumes is a manuscript of Hardyng's Chronicle, a French version of the sacred Scriptures upon vellum, five volumes of Saxon homilies, and a fac-simile of the Vatican Virgil, executed by Bartoli in 1642. To these may be added, a Chinese map, and nearly two hundred drawings, in the first style of eastern art, representing the dresses, customs, and natural history of the interior of China.

[2] This manuscript was purchased by Dr Burney, at the price of six hundred guineas.

The catalogues of the *printed books* are chiefly in two series; first, the printed catalogue of 1812, with manuscript enlargements, now far exceeding in bulk the original, in twenty-two volumes folio; and, secondly, the catalogue of the library of George III. in five volumes imperial folio, with an addendum. There is likewise a catalogue of the geographical and topographical collection attached to the library of George III. printed in one volume folio to match the general catalogue of this library, and also in two volumes 8vo, 1834. All the catalogues are alphabetical; and there is yet no general classed catalogue,[2] although a sum considerably exceeding L.5000 has been paid by parliamentary grants as "expenditure on account of a classed catalogue," and an admirable example of such a work has been furnished in the catalogue of the library belonging to the London Institution.[3] The want of such a catalogue is undeniably a great inconvenience. As are the catalogues of a library, so will be its utility.[4] "What good is the use of a library of more than 200,000 volumes," says Heeren, "if one knows not what it contains, or knows not where that which it does contain is to be found."[5] The catalogues of the *manuscripts* are, 1. That of the manuscripts of the old royal library, by David Casley, 1734, in 4to; 2. That of manuscripts heretofore undescribed, by S. Ayscough, 1782, in two vols. 4to; 3. That of the Cottonian manuscripts, by Joseph Planta, 1802, in folio; 4. That of the Harleian manuscripts, by H. Wanley and R. Nares, 1808, n four vols. folio; 5. That of the Hargrave manuscripts, by H. Ellis, 1818, in 4to; 6. That of the Lansdowne manuscripts, by F. Douce and H. Ellis, 1819, in folio; and, 7. That of the Arundel manuscripts, by J. Forshall, 1834, in folio. Manuscript catalogues of the additions in the departments of printed books and manuscripts to the latest time are kept in the Museum reading-room. There is also a separate manuscript catalogue of the collection of tracts relating to the civil wars in the reign of Charles I.; and a separate catalogue of the Cole manuscripts; besides copies f the catalogue of the Royal Library, printed privately by George IV.

The library of the *Royal Society* is a repository consisting chiefly of books of science and general literature, which may be consulted by all the fellows, and from which books may also be borrowed by them under the egulations prescribed by the statutes; nor have the Society, at any time that is remembered, ever refused to lend ooks or manuscripts to learned men not belonging to their corporation, who had occasion to consult them. The titles of the books presented to the Society have been inserted at the end of the later volumes of their Transactions; they possess no further catalogue. The library of the *Royal Institution* was founded by a few gentlemen, for the immediate use of the subscribers to that establishment; but any person may, upon the recommendation of a patron, always have access to it. This collection contains the best and most useful edition of almost every Greek and Roman classic, with the best translations in English, and some in other modern languages; the class of mathematical science in all its branches is very full, including the best scientific journals, and transactions of learned societies; and the historical department, founded on the collection of Mr Astle, which was purchased by the managers at the formation of the library, is, in its various divisions and subdivisions, exceedingly interesting. A catalogue, methodically arranged, with an alphabetical index of authors, by William Harris, was printed in 1809, in 8vo. The library of the *London Institution* was commenced under the direction of Professor Porson, and has been admirably selected. Next to that of topography, the departments of classical literature, mathematics, and history, are the most amply stocked. It is also rich in bibliography, there being few works absolutely necessary to be consulted by the bibliographical student, which may not be found in this valuable collection. In the "introductory preface" to the methodical catalogue of the library, recently published, there are some judicious remarks as to the importance of classed catalogues. The library of the *Surrey Institution*, though less numerous than either of the two preceding ones, presents a choice collection of the most useful books in the different departments of literature, together with some rare and curious works. The catalogue is systematically arranged, with an alphabetical index of authors.[6]

Modern Libraries.

Lambeth library.

The library of printed books founded by Archbishop Bancroft in the reign of King James I. occupies the four galleries over the cloisters of Lambeth Palace. The number of volumes contained in this library is estimated at upwards of 25,000, many of which are of extreme rarity. In ecclesiastical history and in biblical literature, few collections contain so large a number of scarce and curious editions. The class of English topography is also extensive and valuable. The first catalogue of printed books was drawn up by Bishop Gibson; it was afterwards transcribed in a fair hand by Dr Wilkins, and has been continued by his successors to the present time. The manuscripts, many of which are extremely valuable, are arranged in seven sets or divisions, distinguished as *Codices Lambethiani, Whartoniani, Carewani, Tenisoniani, Gibsoniani, Miscellanei*, and *Suttoniani*. This department, besides being rich in copies of the sacred writings, contains Expositions of the Fathers of the Church; Missals, and Hours of the Holy Virgin; a number of papal bulls; various treatises of Wickliffe; manuscripts relating to the history of France, and other European nations, particularly Spain, Italy, Poland, Germany, and Holland; seventeen volumes in folio of the Shrewsbury correspondence, besides several letters to and from Charles II.; and certain manuscripts on heraldry and genealogy, written or corrected by Lord Burghley. But perhaps the two greatest curiosities in this collection are the ancient French version and exposition of the Apocalypse, ornamented with miniature paintings; and the Latin copy of the Apocalypse, also beautifully illuminated, which is supposed to have been written in the thirteenth century. A catalogue of these manuscript treasures, compiled by the Rev. H. J. Todd, the keeper, was printed in 1812, in one volume folio, at the expense of the Archbishop of Canterbury.[1]

---

[1] Through some want of attention and management, the Museum has lost some collections which it might otherwise have obained, particularly that of Mr Richard Gough, who left his books and manuscripts to the Bodleian Library (*Minutes of Evidence*, 467–1474. Appendix to Report, 413.) In regard to the contents of the Museum Library, see the article under that head in the *Penny Cyclopædia*.

[2] Of the library of George III. there is a classed catalogue in manuscript, made by Sir Frederick Barnard, at Buckingham House; but this," says Mr Edwards, "is not in the reading-room."

[3] This catalogue comprehends, first, a synoptical table of the classes; secondly, a plan of the arrangement, in classes, of the books hemselves; thirdly, a general classed catalogue of all the books; fourthly, an index of authors' names and works; and, fifthly, an ndex of anonymous works, and of many different subjects of which some account is to be found in the library." As to foreign classl catalogues, it is only necessary to mention two examples; first, that of the library of Göttingen, prepared by the celebrated Heyne; and, secondly, that of St Petersburg, an account of which is given in the appendix to the Report on the British Mueum, p. 464, et seq. But that of the London Institution is allowed to be in several respects superior to either.

Oxford libraries.

The different colleges of Oxford and Cambridge have all libraries of various extent attached to them; but in each university there is at least one great or principal library, as the Bodleian Library at Oxford, and that of Trinity College, besides the Public or University Library, at Cambridge.

Bodleian library.

The Bodleian Library, so called from the name of its illustrious founder, was instituted towards the close of the reign of Elizabeth, by Sir Thomas Bodley, who, having become disgusted with some court intrigues, resigned all his employments about the year 1597, and immediately afterwards undertook the generous task of restoring the public library at Oxford, which had been despoiled of its contents in the reign of Edward VI. With this view, he despatched from London a letter to the vice-chancellor, offering not only to restore the building, but to provide a fund for the purchase of books, and the maintenance of proper officers. This offer being thankfully accepted, he commenced his undertaking by presenting to the library a large collection of books purchased on the Continent, and valued at L.10,000. He also collected 1294 rare manuscripts, which were afterwards increased to 6818, independently of 1898 in the Ashmolean Museum. Other collections and contributions were also, by his example and persuasion, presented to the new library. The most important of these, perhaps, was a considerable portion of the very valuable library which had belonged to Jerom Ossorius, the Cicero of Portugal, successively bishop of Sylvas and of Algarve, in which last see he died in 1580. This library having fallen to the share of the Earl of Essex, amongst the booty which had been taken in the expedition against Cadiz in 1598, part of it was by him presented to Bodley, in order to enrich the collection he was then forming. The additions thus made soon swelled to such an amount that the old building was no longer sufficient to contain them. The edifice was accordingly enlarged; and when Bodley had succeeded in enriching his collection beyond his most sanguine expectation, he drew up for its government a body of statutes, which have since been incorporated with those of the university. The Bodleian Library was first opened to the public on the 8th of November 1602; and, since 1780, a fund of more than L.400 a year, arising from a small addition to the matriculation fees, and a moderate annual contribution by such members of the university as are admitted to the use of the library, have been established for the purchase of books. It would require a volume to contain an enumeration of the many important additions which have been made to this library by its numerous benefactors, or to admit even a sketch of its ample contents in almost every branch of literature and science.[2] It is supposed to contain upwards of 160,000 volumes of printed books, and about 30,000 volumes of manuscripts. The oriental manuscripts are the rarest and most beautiful to be found in any European collection; and the first editions of the classics, procured from the Pinelli and Crevenna libraries, rival those at Vienna. In a word, it is exceedingly rich in many departments in which most other libraries are deficient, and it forms altogether one of the noblest collections of which any university can boast; but a complete catalogue of the valuable stores of literature contained in it is still, we regret to say, a desideratum;[3] and, for want of a classed catalogue, the general utility of the collection is materially abridged. The first catalogue of the printed books was published by Dr Hyde in 1674, and another of the manuscripts was printed in 1697. A fuller catalogue of the books, compiled by Bowles, Fisher, and Langford, was printed in 1738, in two volumes folio; but, from the immense increase of the collection since that period, this, as well as the others, has become of little use. A catalogue of the manuscripts relating to oriental history, drawn up by Professor Urie, was printed in 1787, in one volume folio. In 1795, there was also printed a *Notitia* of first, early, or Aldine editions of certain Hebrew, Greek, and Latin works contained in the library, the articles indicated being all of the greatest rarity; and, in 1812, appeared the first part of a catalogue by Professor Gaisford, of the manuscript collection purchased by Dr Edward Daniel Clarke, in his travels through various parts of Europe and Asia. But no complete or general catalogue, either of the printed books or the manuscripts, has yet been published; and for this reason it is impossible to give any specific or satisfactory account of this magnificent collection.

The riches of the Bodleian Library are very imperfectly known to the world, and its stores are increasing faster than they can be catalogued; yet the library is not generally accessible, even to the students of the university; and the arrangements are such, that the very persons engaged in teaching have but a limited use of it. The average number of daily readers is stated to be about half a dozen; whilst, in the British Museum, it is at least one hundred and fifty. The books of the Bodleian Library are not allowed to go out, and, by this restriction, its utility is greatly abridged. The use, to a reasonable extent, of a collection which is certainly one of the best in the world, would of itself form a strong inducement to study at Oxford; and it is inconceivable how this advantage should have been withheld, considering that the terms in which Sir Thomas Bodley made his donation to the university present no obstacle whatever to the lending out of books.[4]

The libraries of the different colleges are many of them considerable, some of them extensive, and not a few of them enriched with much that is both curious and rare. Bishop Rede contributed the first part of the collection of books in Merton College, which has since been augmented, both in manuscripts and in printed books, by the liberality of succeeding benefactors. University College Library possesses a considerable collection of printed books and manuscripts, together with some works of art. Baliol College Library suffered by the depredations of the visitors appointed by Edward VI.; but the damage was afterwards repaired by a supply of books from Durham College, and by successive donations. The library of Queen's College contains some curious manuscripts, chiefly heraldic and political, a valuable series of coins, a collection of numismatical works, and a fine orrery. The books of New College occupy two spacious apartments, and there is also a collection of manuscripts. The library of Lincoln College is chiefly remarkable for a collection of Greek and

Modern Libraries.

Latin manuscripts made by Sir George Wheler in his travels. That of All-Souls' College is an excellent collection; it was admirably arranged, under the superintendence of Sir William Blackstone; and the greatest facility is consequently afforded in consulting any class. In the library of Brazen-nose College, the ancient custom of chaining the books to the shelves was strictly observed until the year 1780, when this conservative practice was abandoned. This collection is of considerable extent and value. The library of Corpus Christi College is enriched with a valuable set of Aldine classics, with many manuscripts and printed books, of great rarity and in excellent preservation, and with the manuscripts of Twyne and Fulman, the Oxford antiquarians. The Aldines were collected by the founder, Richard Fox. In 1755, Lord Coleraine gave to this library a large and valuable collection of Italian literature. The library of Christ Church would probably have exceeded that of any contemporary establishment, had Wolsey been able to complete his original design, which was, not only to supply it with such books as had appeared since the invention of printing, but also with copies of the most valuable manuscripts in the Vatican. This collection is principally composed of the extensive and valuable library bequeathed by the Earl of Orrery, amounting to 10,000 volumes; of that left to the college by Wake archbishop of Canterbury, consisting of printed books and manuscripts, with a collection of coins and medals; and of the contributions of a number of benefactors. In 1767, the numismatical series was further enriched by the collection of British and English coins belonging to Dr Barton, and, in 1780, by that of oriental coins collected by Dr R. Brown, canon and regius professor of Hebrew. The library of Trinity College was instituted by the founder, Sir Thomas Pope, who was also the first contributor of books. The collection was afterwards enlarged by various benefactions, and is now one of considerable extent. The library of St John's College contains a valuable collection of printed books and manuscripts given by Archbishop Laud; many specimens of natural and artificial curiosities, and relics of antiquity; with a collection of Greek, Roman, and English coins, bequeathed by Dr Rawlinson, along with his books. In the library of Wadham College are many early printed books, and a good collection of classics and works on theology, together with French, Italian, and Spanish literature. The library of Worcester College is a considerable collection, and particularly rich in architectural books and manuscripts. The Radcliffe Library, so called from the munificent founder, Dr Radcliffe, who left L.40,000 for the erection of a public library in Oxford, with an endowment of L.150 a year to a librarian, and L.100 for the purchase of books, is an extensive and valuable collection, and contains some valuable but neglected manuscripts.[1]

The library of Trinity College, Cambridge, is extensive, and contained in a very magnificent structure built by Sir Christopher Wren, being two hundred feet in length, forty in breadth, and thirty-eight in height. The collection is separated into thirty classes, distributed in cases of oak; and the books are both numerous and valuable. Amongst other literary curiosities, there are some interesting manuscripts in the handwriting of Milton. They are contained in a thin folio volume, which was discovered by Professor Mason amongst the papers of Sir Henry Puckering, and consist of the original copy of the Masque of Comus; several plans of Paradise Lost, composed at the period when he intended to have made that subject the groundwork of a tragedy; and the poems of Lycidas, Arcades, and several others. Here are also the Arabic manuscripts left by Dr Gale, and the collection relating to English antiquities by his son Dr Roger Gale; Sir Isaac Newton's copy of his *Principia*, with his manuscript notes, and his letters to Roger Coles; and the voluminous Shakspeare manuscripts and printed books of Edward Capell, a catalogue of which was printed by Mr Steevens.[2]

The University or Public Library of Cambridge is extensive, and contains much that is valuable or curious both in the department of printed books, and in that of manuscripts. The printed books comprise a fine series of *editiones principes* of the classics, and a very considerable proportion of the productions of Caxton's press. The most important acquisition made by this library was that of the collection which had belonged to Dr Moore, bishop of Ely, amounting to 30,000 volumes, which were munificently purchased for six thousand guineas by his majesty King George I., who presented them to the library, and further gave L.2000 towards fitting up the apartments destined for their reception. Bishop Moore's collection, which is singularly rich in the productions of the early English printers, was offered to the Earl of Oxford for L.6000, and on his refusal was purchased and presented as has just been mentioned. A method of arranging the books in the public library of Cambridge was long ago proposed by Dr Middleton, but no catalogue of them has yet been printed. The number of volumes in this library must now considerably exceed 100,000. Amongst the manuscripts contained in it are, 1. the celebrated manuscript of the four Gospels and Acts of the Apostles, known by the name of the *Codex Bezæ*, which was presented to the university by that distinguished reformer; 2. *Magna Charta*, written on vellum; 3. several very valuable manuscripts purchased at the sale of Dr Askew's collection; 4. some curious Syrian manuscripts presented by the Rev. Dr Buchanan;[3] 5. a Coptic manuscript written upon long narrow papyrus, with an ancient stylus; and, 6. a Koran upon cotton paper, superbly executed.

The library of Bene't College contains a number of manuscripts. Those which were collected after the dissolution of the monasteries relate to the writings of the fathers, school divinity, the reformation, civil and ecclesiastical affairs, and the concerns of various religious houses; and many of them are in the old Saxon character. St John's College Library contains one of the most valuable and extensive collections of books in the University, particularly in biblical and classical literature, and is also enriched with some first editions which came originally from the Harleian collection. The Pepysian Library, Magdalen College, is so called from the founder, Samuel Pepys, secretary to the admiralty in the reigns of Charles II. and James II. who bequeathed to this college his valuable library, together with his prints and drawings. It is remarkable for a collection of old English ballads, in five volumes folio, begun by Mr Selden, and continued to the year 1700; and two volumes of Scottish poetry, consisting of pieces by Gawin Douglas, Dunbar, Lindsay, Drummond, James I. and other poets. Dr Percy, in his *Reliques*, has made a judicious selection from the former; and, in 1776, Mr Pinkerton published copious extracts from the latter. Pepys's collection of prints and drawings, illustrative of the history of London, and his rare British portraits, are particularly valuable.[1]

---

[1] The state in which William Augustus Schlegel found a manuscript fragment of the *Ramayana* in the Radcliffe Library, shows that the condition of oriental manuscripts in England is not satisfactory, and that things least used are not always best cared for. The following is his own account of the matter:—"We commenced a diligent search; at last we drew forth from a press which had long been unvisited, the separate and torn portions of manuscripts, covered with dust and dirt, and leaves rolled up together promiscuously. Oh, what destruction did I then see! Nothing was ever scattered more confusedly from the Sybil's cave into every quarter of the heavens, when the leaves on which she used to write her oracles were carried away by a sudden storm. I was not able to examine them all, for I was in haste to return home, it being late in the autumn. I selected, however, from the midst of that disgraceful confusion, a fragment of the *Ramayana*, and I put together almost the entire manuscript of the poem '*de Crishni ἐπιφανεια* (*Srî Bhâragavata-Purâna*)' and I re-arranged as many of the leaves as I could find, in their order. I had already noticed the unusual antiquity of the writing, and I read with no small astonishment these dates at the end of the books, 'Samvat, 1461–1463,' A. D. 1405–1407. The most ancient in the King's Library at Paris is a manuscript of the same poem, which was written sixty-five years after, 'Samvat, 1528, A. D. 1472.' The university of Oxford, therefore, although still ignorant of its wealth, possesses a manuscript which is most rare, and indeed unique in Sanscrit literature." This statement requires no comment. (*Journal of Education*, vol. i. pp. 403, 404.)

Early in the present century, a public infirmary, and an astronomical observatory, now amply supplied with astronomical instruments, were erected from the funds still in the hands of Dr Radcliffe's trustees.

Earl Spencer's library.

The library of Earl Spencer, at Althorp, Nottinghamshire, though a private collection, is eminently deserving of notice here, not so much by reason of its extent, which is very considerable, as on account of the unrivalled treasures which it contains in several departments of literature, sacred as well as profane. This library, amounting to not less than 45,000 volumes, exclusively of the Cassano collection purchased in 1820, was entirely formed by the late Earl Spencer, within a period of time not exceeding twenty-four years; and it is unquestionably the richest private collection in Britain, perhaps in Europe.[2] The foundation of the department of books printed in the fifteenth, and of valuable first editions published in the sixteenth century, was laid by the purchase of the collection of Count Reviczky, a foreign nobleman who had occupied himself in accumulating rare and curious works of a peculiar description. But many scarce and valuable impressions of the classical authors were afterwards obtained; and in the departments of literature and the belles-lettres it was enriched with some magnificent acquisitions. Impressions of Bibles and Testaments, and of portions of the sacred text in almost all languages, are to be found in this extraordinary collection; the departments of classical literature, in the Greek, Latin, and Italian languages, are of equal, if not greater extent and value; whilst the choice, condition, and splendour of the entire collection are such as render it quite unique and unrivalled.[3] But, perhaps, its most remarkable feature is the unexampled assemblage to be found in it of works illustrating the origin and progress of typography. It contains several books, consisting of impressions taken from carved wooden blocks previously to the invention of metallic types, and thus exhibiting the earliest specimens of stereotype printing. In others, engraved figures constitute the principal part, to which is added a small proportion of text, and only one side of the leaf is employed, the other being left blank. Such is the *Ars Memorandi Notabilis per Figuras*, supposed to have been thrown off previous to the year 1430, and consisting of a number of rude cuts of the principal events recorded in the Gospels, with text on the opposite page; and such, also, is the *Ars Moriendi*, the subject of which is a sick man in bed, surrounded by grotesque and hideous figures of angels and demons. The taste of the time inclined to the monstrous or the absurd. In the former work St Luke is represented by a bull standing on his hind legs, whilst St Mark is depicted as a rampant lion. The *Historia Veteris et Novi Testamenti seu Biblia Pauperum*, also in this collection, is supposed to have been executed prior to the year 1450, and is by some considered as the earliest specimen of block-printing. Amongst the early printed and scarce bibles in the Althorp Library, may be mentioned the Mazarin Bible, printed between 1450 and 1455; one supposed to be the work of Albert Pfister, prior to 1460; Fust and Schœffer's Bible, 1462; that by Sweyheym and Pannartz, 1471; a Dutch Bible, 1477; Prince Radzivil's Bible in Polish; besides other early copies in the different languages of Europe. The same collection contains the Latin Psalter of Fust and Schœffer, printed in 1457, being the first printed to which a date is affixed; and another of nearly equal rarity, printed in 1459. Many of the earliest editions of the classics, beautiful copies on vellum, and the works of all the celebrated printers of the fifteenth century, add to the value of this unrivalled collection. The Cassano Library,[4] purchased by Earl Spencer in the year 1820, and soon afterwards united with his general collection, formed a valuable addition to the Althorp Library. Amongst other rarities, it contained the famous edition of Horace, printed at Naples in 1474, by Arnoldus de Bruxella, of which there is no other known copy; that of Terence, printed by Riessinger, without date, but probably not later than 1471; the earlier productions of the Neapolitan press; rare editions of the early Italian classics; specimens of early printing at Rome, including the edition of Juvenal by Ulric Han; together with all the rare editions of Virgil, Horace, Ovid, and other Roman poets.[5]

Advocates' library.

We come now to Scottish libraries, and shall commence with the largest as well as richest of the number; that of the Faculty of Advocates. The plan of forming a library appears to have been adopted by the Faculty as early as the year 1680. The author and active promoter of the scheme was Sir George Mackenzie of Rosehaugh. It was originally intended that it should consist merely of the works of lawyers, and of such other books as were calculated to advance the study of jurisprudence. This may be inferred from the inaugural address delivered by Sir George Mackenzie when the library was first opened, and from several other papers relative to the subject. At its commencement, this library had no certain fund allotted for its maintenance. It depended upon and owed its increase to the donations of benefactors, together with such sums as the Faculty from time to time placed at the disposal of the curators. In the year 1700, the apartment where the library was kept being nearly destroyed by fire, it was removed to the place which it partly still occupies, namely, the ground floor of the Parliament House. During the nine years immediately following, it must have increased considerably,[6] since by the act passed in the eighth year of Queen Anne's reign, the privilege of receiving a copy of every book entered at Stationers' Hall was conferred upon it, alongst with eight other libraries, four of which were Scotch, being those attached to the universities of St Andrews, Glasgow, Aberdeen, and Edinburgh.

The department of printed books comprehends, in a greater or less degree, almost every branch of science, philosophy, jurisprudence, literature, and the arts. As might be expected, the collection of law-books is extensive; but it is much more complete in ancient than in modern works, many important treatises on foreign jurisprudence being still wanting. The historical collection, which is exceedingly valuable, contains almost every work of consequence that has been published in Great Britain, France, Italy, Spain, Portugal, Denmark, and Sweden. This department alone comprehends upwards of 20,000 volumes. The collection of Greek and Roman classics, though it cannot vie with some others, is also choice and extensive, including several first and many early editions. The library is rich in modern poetry and belles-lettres, and, besides the miscellaneous department, contains a very considerable collection of voyages and travels. It is defective in the great branch of mathematical and physical science; in archæology or antiquities; in early as well as modern Italian literature; and, generally, in foreign literature of a recent date. Amongst the separate collections are, the Astorga library, the Thorkelin collection, and that of old Scottish books. A collection of Spanish books, amounting to about 3400 volumes, which had formerly belonged to the library of the Marquis of Astorga, was purchased from a London bookseller in 1824, for the sum of L.3000. It consists principally of works on Spanish history, including the old chronicles, as well as of books on law and theology, with a sprinkling of the old Spanish poems and romances. The Thorkelin collection, so called from Professor Thorkelin, to whom it originally belonged, contains about 1200 volumes, chiefly on northern law, history, and antiquities. Of the Scottish books, those relating to old Scottish poetry are exceedingly rare and curious. They amount to between three and four hundred volumes, and their number is likely to be still further increased by the zeal and research of the present librarian, Dr Irving, who has already made many important additions to this collection, partly by the acquisition of new articles, and partly by detaching curious pieces from other collections, and putting them in a distinct and more accessible form. His labours in this department, with which he is intimately conversant, have been beyond all praise; and he is constantly on the watch to take advantage of every opportunity that offers for augmenting its treasures. There is also a collection of German dissertations, amounting to upwards of 100,000, called Count Diedrich's collection, which was purchased by Sir William Hamilton, on account of the library, for the trifling sum of L.80. This library is not rich in typographical rarities. It contains few Caxtons, and, with the exception of the Mentz Bible, and some specimens of early printing in Scotland,[1] has but little to interest those who delight in the productions of the press during the infancy of the art. The total number of printed volumes contained in the library does not, it is thought, fall much short of 150,000.

[5] See Supplement to the *Bibliotheca Spenceriana*, forming vol. v. of that Descriptive Catalogue of the Books printed in the Fifteenth Century, &c. London, 1823.

[6] In 1707, the library received a large donation of books in natural history, to which many of the most costly and magnificent works on that branch of science have since been added.

The department of manuscripts, though not so extensive as in some other libraries of the same class, is nevertheless of great interest and value with reference to the civil, and particularly the ecclesiastical history of Scotland. Soon after the foundation of the library, the Faculty appear to have turned their attention to the collection of manuscripts; and this important department now consists of nearly 1700 volumes, of which about 250 have been added within the last fifteen years. The most valuable portion of the manuscripts is that which relates to the ecclesiastical state of Scotland immediately preceding the era of the Reformation, and includes, amongst other things, thirteen chartularies or volumes of records of the different religious houses, which escaped the general destruction in which the edifices themselves were then involved. Considerable light is also thrown on the civil and ecclesiastical history of Scotland at a later period, by the documents and other materials contained in the collections of Sir James Balfour, Sir Robert Sibbald, and Wodrow the historian. Balfour's collection, which consists of upwards of sixty volumes, was purchased at a considerable expense in 1698. About the half of it consists of original state papers, and several very curious royal letters written in the times of James VI. and Charles I. From these, selections were made by Lord Hailes, and printed in 1762 and 1765. The Annals of Scotland, compiled by Sir James Balfour, were also printed in 1824, 1825, in four volumes 8vo. But there still remain unprinted some manuscripts on genealogy and heraldry, besides a considerable number of curious documents. Sir Robert Sibbald's collection, consisting of upwards of thirty volumes, was purchased by the Faculty in 1723. It is chiefly of a topographical and literary character; but the substance of the greater part relating to topography has already been published. Wodrow's collection is by far the most voluminous, consisting of upwards of 160 volumes. It was chiefly from this immense mass of materials that that laborious writer compiled his History of the Sufferings of the Church of Scotland; but by far the greater portion of the collection, containing many curious original documents not to be met with elsewhere, is still unprinted. His correspondence with many eminent literary characters, embracing a period of more than thirty years (from 1694 to 1726), and extending to about thirty volumes, is also full of curious information respecting the literature and history of the period to which it refers. A collection of original documents belonging to the reigns of James V., Queen Mary, and James VI., was presented to the library by the Earl of Balcarras in the year 1712; these papers have lately been arranged and bound, and now consist of nine volumes folio. This department also contains Lord Fountainhall's collections, in his own handwriting, including his decisions, historical notices, diary, and other matters. We may likewise notice the curious and interesting papers of Paton, Murray, Anderson, and Hutton, all of which have recently been arranged and bound in several folio and quarto volumes; and also those collected by Mr Scott of Perth, consisting of about twenty volumes folio, and comprising the Blackfriars charters, in three volumes, extracts from the records of the Church of Perth, in four volumes, the records of the Hospital from 1577 to 1732, extracts from the records of the Kirk-session, a chronicle, and a register of baptisms and deaths. Amongst the Scottish historical records are, letters from James V., and the Earl of Arran, governor of the kingdom in the infancy of Queen Mary, to the kings of England, France, Norway, and Portugal, to the Duke of Guise, the Earl of Suffolk, and others, from 1539 to 1542: also original letters by Queen Mary, addressed to her mother the queen-dowager, during the early years of that beautiful but ill-fated princess; by Anne of Denmark, queen of James VI.; by Prince Henry and Prince Charles, his sons; by the Princess Elizabeth, his daughter; and by the Elector Palatine and his son to James VI., entirely of a familiar nature.

---

[1] The first production of the Scottish press preserved in this library should not pass unnoticed. It is a breviary composed by the bishop of Aberdeen for the use of his cathedral, and printed in the year 1509; and it consists of two volumes in small octavo, but of the first volume the title-page and some leaves at the end are wanting. The second volume, printed in 1510, has at the beginning a calendar, and at the end these words: "Opido Edinburgensi impresso jussu et impensis honorabilis viri Walteri Chepman ejusdem opidi Mercatoris quarto die Junii milesimo CCCCC decimo." On the outside of this leaf is a wooden engraving representing a man and woman clothed in skins of beasts, with their shoulders bare, and their heads adorned with wreaths of flowers; whilst between them stands a tree, from which is suspended a shield with W. C. in cipher.

The same department includes a number of manuscripts on heraldry, genealogy, and Scottish law, besides many of a miscellaneous nature. It also contains several early manuscripts of the classics, and a few illuminated missals. Amongst the former may be mentioned a very fine copy of Horace, belonging to the thirteenth century; the plays of Terence, executed in the year 1436; a copy of the Epigrams of Martial, in perfect preservation, which, from the style of the writing, has been ascribed to the ninth century, and is supposed to be one of the most ancient manuscripts of the Epigrams extant;[1] a copy of Valerius Maximus, beautifully written on vellum, dated 1398; Lactantius *De Opificio Dei*, a gem of its kind; the mathematical collections of Pappus of Alexandria, written in beautiful Greek, with admirably-executed diagrams; besides portions of several classics, as Cicero, Ovid, Juvenal, and Persius, all of considerable antiquity. A manuscript copy of St Jerome's translation of the Bible, supposed to have been written about the tenth century, and said to have been found in the Abbey Church of Dunfermline during the reign of David I.; the Auchinleck manuscript, from which Sir Walter Scott printed the Romance of Sir Tristrem; and Bannatyne's manuscript, in two volumes folio, being a collection of ancient poems made by different learned Scotchmen, lovers of antique song, and "written by Geo. Bannatyne in the time of his youth, 1568;"[2] likewise adorn this department of the library. It was from the Bannatyne collection that Allan Ramsay selected the poems which were printed in the Evergreen; and from the same source Lord Hailes extracted a volume, which was printed in the year 1770. In 1825, about a hundred volumes of Icelandic manuscripts, amongst which are several ancient Sagas, were purchased of Professor Magnuson of Copenhagen, and added to the collection; and in the following year, Mr Elphinstone, and Mr Erskine, formerly of Bombay, presented to the library some valuable Persian and Sanscrit manuscripts. Not long ago a beautiful manuscript of the Hebrew Bible was purchased in Germany; it is in two large folio volumes; and the Pentateuch, besides the original, has also the Chaldaic paraphrase. A manuscript of the *Corpus Juris Civilis*, well executed, but of uncertain date and doubtful authority, and, in several respects, exceedingly defective, was likewise purchased several years ago.

The building which contains the bulk of the Advocates' Library is not only confined, but is in several parts exceedingly dark and inconvenient. The historical department, however, has been separated from the rest of the collection, and arranged in a spacious and elegant apartment, with convenient side-rooms, recently provided for its reception, being intended to form the grand entrance to a large building which it is proposed to erect for the reception of the great body of the library, as soon as the necessary funds can be obtained. The library is governed by five curators, one of whom goes out of office annually by rotation, and another is elected in his stead from amongst the body of the Faculty. Under the curators are a principal keeper or librarian, and several assistants. The library is supported partly by the acquisitions which it is continually making in virtue of the right conferred upon it by the copy-right act, and partly by an annual sum paid to the curators for the use of the establishment out of the revenue of the Faculty. No public institution in Great Britain, or perhaps in Europe, is conducted with greater liberality than the Advocates' Library. Strangers arriving in Edinburgh are freely admitted without introduction; and any one who is at all known is never denied the privilege of resorting to, and of reading or writing in, the library. Very eminent men have been keepers of this collection, particularly Thomas Ruddiman, David Hume, and Adam Ferguson. The present librarian, Dr Irving, well known by his Life of Buchanan and other works, is a distinguished scholar, a learned civilian, and eminently skilled in ancient Scottish history, biography, and poetry.

The first volume of the general catalogue was begun in 1735, and printed in 1742, under the superintendence of the learned Ruddiman and Mr Walter Goodall; the second, consisting of later acquisitions, was compiled by Mr Alexander Brown; and this was followed by a third volume, printed in 1807, all in folio; but the manuscript additions which have since been made are at least equal to other two printed volumes of the same size. There are manuscript catalogues of the Astorga and Thorkelin collections; but as yet there exists no separate catalogue of the manuscripts. A catalogue of the law-books was printed in 1831, in one volume 8vo. There is no classed catalogue of the Advocates' Library, nor even a classed index to the general catalogue, which would be a great convenience to those engaged in scientific or literary pursuits.

Library of the Writers to the Signet.

The library of the Writers to his Majesty's Signet is an excellent and valuable miscellaneous collection of books in science, law, history, geography, statistics, antiquities, literature, and the arts; and it has recently been rendered much more accessible by the ample and spacious accommodation provided for it. It is contained in two large and beautiful apartments, both under the same roof, with small rooms adjoining. The accommodation altogether is perhaps superior to that of any library in Britain. The books are arranged in classes or departments, not in conformity to any particular bibliographical system, but with reference simply to the nature and extent of the collection, and the circumstances necessary to be attended to in placing it in the particular apartments which it occupies. The arrangement, however, is such as to afford facilities for reference, and to exhibit, in a general way, the component parts or branches of the collection. The upper apartment, in which about 14,000 volumes have already been placed, contains the following classes, viz. theology and ecclesiastical history; general and particular history, biography, and antiquities; arts and sciences; transactions of learned societies, encyclopædias, and dictionaries; polygraphy, or the collected works of authors who have treated on various subjects; classics, translations, and works illustrative of the classics; and, lastly, belles-lettres and miscellaneous literature in the learned as well as in foreign languages. The lower apartment, and the adjoining small rooms, contain the classes of civil, Scottish, English, and foreign law; British and Irish history, biography, antiquities, topography, and statistics, with all works relating to these heads; geography, voyages and travels; bibliography; belles-lettres, in the English language, and the miscellaneous productions of British literature; besides collections of periodical publications, parliamentary reports, and parliamentary debates, with a collection of maps suspended in spring cases. The class comprising works relating to the history, biography, antiquities, topography, and statistics of the British empire, forms the most extensive department of this collection, and is, in fact, nearly complete in most of its subdivisions. The choice and condition of the books generally, and the rarity, value, and splendour of many, deserve particular notice; and, indeed, this library, though supported exclusively from the funds of the Society to which it belongs, possesses some of the noblest and most expensive works ever published, either abroad or at home. The number of volumes may be estimated at nearly 50,000. There is a classed catalogue, formed on De Bure's system, and very skilfully executed, which was printed in the year 1805; but this applies only to a small portion of the collection, which has been very greatly increased since the catalogue in question was prepared. An alphabetical catalogue of the whole collection has been printed, in progressive parts; and to this there is now (1836) in the Press, a *classed index*, which will, in a great measure, supply all the advantages of a catalogue raisonné. The government of the library is vested in a body of curators, elected by the Society; and under them are a principal librarian and several assistants. Here, as is the case of the Advocates' Library, the utmost liberality is shown to strangers, and to literary men generally.

---

[1] An account of this manuscript was published by Mr Dalyell in 1811, in 8vo, two copies of which were printed on vellum.

[2] Bannatyne's manuscript was presented to the library, in the year 1772, by the Earl of Hyndford.

Like most other college libraries, that of the University of Edinburgh was founded by a donation; and, for a long period, the casual contributions of benefactors constituted its principal means of support as well as of increase. In 1580, Mr Clement Little, commissary in Edinburgh, bequeathed his library, consisting of about 300 volumes, chiefly theological, to Edinburgh and the Kirk of God; and this small collection was, not long afterwards, transferred by the Town Council to the College, which they were then instituting. Little's bequest thus laid the foundation of the University Library. But it was subsequently augmented, partly by the donations of citizens, and still more by the benefactions of persons who had received their education in the College. Amongst the latter may be mentioned, Dr Robert Johnston, the Rev. James Nairne, and, above all, Drummond of Hawthornden, one of the favourite sons of the Scottish muse. Drummond bequeathed to the College his whole library, consisting of about 500 volumes; and the gift is the more valuable, because, independently of the high reputation of the donor, the collection is enriched with many rare specimens of our early literature, and may indeed be considered as altogether unique and unrivalled. In 1763, the library of the incorporation of surgeons was added to that of the College, in consequence of an agreement, which has eventually proved eminently advantageous to the former body, whatever may be the case in as far as regards the interests of the University. This collection consisted of about 500 volumes, almost entirely professional, and now of very little value. The principal bequest which the library has more recently received is that of Dr William Thomson, who, in 1808, left it about 600 volumes, chiefly on medical subjects. In a testamentary bequest by the late General Reid, who was educated at this university, mention is made of the library, as an object to the improvement and extension of which, his munificent legacy is, amongst other things, to be applied. The funds by which the library is maintained, and its progressive enlargement secured, are, matriculation fees, fees on graduation in three faculties, a donation of L.5 from each professor on his induction, an annual payment of L.20 by the College of Surgeons, occasional donations of books, and its acquisitions as one of the privileged libraries; but from the sums thus realized are of course to be deducted the salaries of the persons employed in the establishment. The ordinary management of the library is vested in nine curators appointed annually by the Senatus Academicus, four of whom retire from office every year, and are immediately succeeded by an equal number of professors next in seniority, who are willing to undertake the duty. Four of these curators are from the medical, one from the theological, and four from the general department, including classes neither medical nor theological.[1] This library consists of about 90,000 printed volumes, including some great typographical rarities; and the accommodation now provided for it is of the most magnificent description, the library-hall being by far the most spacious and noble apartment in Scotland. As to the collection generally, it contains much that is valuable, and a good deal that is both curious and rare; but, considered as a repository of varied information in science and literature, it is unequal and defective, being redundant in some branches and deficient in others. Its most ample department is that of medicine, a purely professional one, and more largely replenished than any other with obsolete matter. Those of natural philosophy and natural history are tolerably supplied with the works belonging to them. But the case is different in the departments of metaphysical, ethical, and political science, in all of which the deficiencies are still great, though, happily, in the way of being gradually supplied. In classical literature, too, including under that head all that relates to the exposition and illustration of the ancient authors, there are perhaps few great libraries more defective.[2] It is to be hoped, however, that every exertion will be made, not only to supply obvious and glaring deficiencies, but also to give to the collection that character of generality, founded upon the possession of all that is most useful and interesting in every branch of knowledge, which constitutes the best recommendation of a great public library. This it is which has imparted to the library of Göttingen its great and acknowledged excellence. The only catalogue yet printed is one of the books relating to medicine, arranged alphabetically according to the names of the authors.[3] In addition to the public, there is attached to the university a theological library, founded towards the close of the seventeenth century, and now containing about 5000 volumes.

Glasgow University library.

The history of the library of Glasgow College, though curious and interesting, is chiefly a register of the numerous successive donations by which it was gradually formed. Amongst the names of its early benefactors we find that of George Buchanan, who, it appears, presented to the college twenty volumes, consisting entirely of Greek works, chiefly classics,[4] and made other benefactions, the extent of which cannot now be ascertained. This library is said to contain upwards of 30,000 volumes; and the funds for its support are derived from the interest of certain small sums bequeathed by individuals, from graduation fees, and from the contributions of students, including the interest accruing from the deposit money. It also enjoys the privilege of receiving books from Stationers' Hall.[5] Amongst the manuscripts in this library are several volumes by Wodrow, principally on biography. A catalogue of the printed books, by Professor Arthur,[6] appeared in 1791, and, we presume, is the one still chiefly consulted, though considerable additions must have been made since it was printed.

St Andrews University library.

There was very early a library in each of the colleges at St Andrews; but no mention is made of an university library until about the commencement of the seventeenth century. At that period, there occurs a notice of such a collection; and a catalogue of its contents, made at the time, is still extant, the books being chiefly presents from James VI. and the members of his family. With this public university library, those of St Salvator's and St Mary's Colleges came, in process of time, to be incorporated; and, rather more than half a century ago, that of St Leonard's College, the best of the collections, was conjoined with the rest. As now constituted, the library is supported by the interest of money made up out of the excess of the receipts above the expenditure of its funds, the surplus rent of some teinds and lands held in lease from the exchequer, certain fees on graduations, and an annual payment by every student of the university, exclusively of its right to receive books from Stationers' Hall.[1] It contains about 35,000 printed volumes, and is, upon the whole, an excellent collection. There is a printed catalogue to the year 1826, and a progressive manuscript one since that time.

Libraries of Aberdeen Colleges.

There is reason to believe, that from the first institution of the university of Aberdeen there was a collection of books at King's College, but no particular record of the library or its management, prior to the year 1634, is now to be found. The collection is considerable, containing from 15,000 to 20,000 printed volumes, and a number of manuscripts. Amongst the latter are, a splendid copy of the Koran, said to have belonged to Tippoo Sahib; a work on Hindu theology, written upon fine vellum, and rolled on a piece of ivory like the *volumina* of the ancients; and a Shaster in Sanscrit, written on the leaves of trees. This library is entitled to a copy of every book entered at Stationers' Hall. Its funds, however, are altogether inadequate, not only for the purchase of new, and particularly foreign publications, but even for binding the books obtained from Stationers' Hall, in the way proper for a public library. The library of Marischal College had its origin in a collection of books made at the time of the Reformation by the magistrates of Aberdeen, and partly procured from the suppressed monasteries of that city.[2] The number of volumes in it is about 11,000. The funds for supporting this library arise from fees of graduation, and the interest of a sum of money amounting to rather more than L.900. The principal and professors of Marischal College have a right to the use of the books transmitted from Stationers' Hall, and deposited in the library of King's College.[3]

Library of Trinity College, Dublin.

The library of Trinity College, Dublin, owed its establishment to a very curious incident. In the year 1603, the Spaniards were defeated by the English at the battle of Kinsale. Determined to commemorate their victory by some permanent monument, the soldiers collected amongst themselves the sum of L.1800, which they agreed to apply in the purchase of books for a public library, to be founded in the then infant institution of Trinity College. This sum was placed in the hands of the celebrated Usher, who immediately proceeded to London, and there purchased the books necessary for the purpose. It is a curious coincidence, that Usher, whilst occupied in purchasing these books, met in London Sir Thomas Bodley, engaged in similar business, with a view to the establishment of his famous library at Oxford. From this commencement, the library of Trinity College was at different periods increased by many valuable donations, including that of Usher's own collection, consisting of 10,000 volumes, until at length its growing magnitude requiring a corresponding increase of accommodation, the present library-hall, a magnificent apartment of stately dimensions, was erected in the year 1732. In 1787 the entire collection consisted of 36,047 volumes of printed books, and 1111 volumes of manuscripts and prints. But since that time great additions have been made to the library. When the French invaded Holland in 1794, the collection of Pensionary Fagel, amounting to upwards of 20,000 volumes, was removed to England, where, in 1802, it was purchased by the College for the sum of L.8000, granted for the purpose by the trustees of Erasmus Smith.[4] Another important addition was made to the original collection by the acquisition of the valuable classical and Italian books which had belonged to Mr Quin; and, altogether, the library of Trinity College now forms one of the first order, at least in this country. In the department of printed books, the total number of volumes is now supposed to fall little short of 100,000. The Usher manuscripts amount to 693, the Stearne to 135, the Stearne and Alexander to 77, and those presented by other persons to upwards of 200 volumes. Usher's manuscripts may be classed into Bibles, and parts of Bibles, with commentaries; breviaries, missals, Roman rituals, the works of the fathers, and oriental writers; systematic, scholastic, and polemic writers; catalogues, philosophical, medical, and historical; and, lastly, Irish histories and genealogies, civil and ecclesiastical. The subjects of the Stearne manuscripts are somewhat similar to these, with the exception that some of them treat of forensic subjects.[5] In this department of the collection, there is preserved the Gospel of St Matthew, along with other fragments of Scripture, written in Greek capitals, and ascribed by Dr Barrett to the sixth century.

Foreign Libraries.

Having described the principal libraries of Great Britain and Ireland, we shall now proceed to those of foreign countries, and, in particular, endeavour to give some account of the principal collections in France, Spain, Italy, Germany, Poland, Russia, Denmark, and Sweden. This account, however, must necessarily be brief and imperfect; for, owing to the magnitude of the subject, the space we can devote to the whole would scarcely be sufficient for an adequate description of the treasures contained in the Vatican or the Royal Library at Paris.

The libraries of France may be divided into those of the capital, and those of the departments. The principal lib-

---

[1] App. to Report, p. 413.

[2] These books were retained in one of the churches, under the care of the magistrates, and were called the Town's Library, and *Bibliotheca Ecclesiastica.* On the 19th of May 1624, Mr Thomas Reid, Latin secretary to James VI., bequeathed his books to the college, and left 6000 merks to the town, the interest of which was to be applied as a salary to a librarian. Reid's collection was afterwards united to the *Bibliotheca Ecclesiastica*, and to the books bequeathed by Dr Liddel, and other benefactors; and the whole, forming one collection, was deposited in the college, of which it now constitutes the public library. (See Appendix to the *Report of Commission on the Universities and Colleges of Scotland*, p. 361.)

[3] App. to Report, p. 361.

[4] The Fagel collection being at first intended for sale by public auction, a classed catalogue by Mr Samuel Paterson was printed in the beginning of 1802. Speaking generally of this collection, in the preface Mr Paterson says, "It is one genuine library, which has been accumulating in the family of Fagel, a name of the first respectability, and which has borne in succession the highest civil offices in the united states of the Netherlands upwards of one hundred and twenty years. It abounds in many of the choicest books in theology and ecclesiastical history, in classical and philological learning, and in most branches of polite literature, arts, and sciences; it includes almost all the great *corpora* of history, antiquities, and diplomatic science; the books of prints, archaiological, numismatical, and topographical (which are very numerous), are commonly of the best impressions: as an historical, geographical, genealogical, and statistical library, it may justly rank among the most distinguished."

Modern Libraries. raries of the capital are, the Royal Library, the Mazarin Library, the library of the Arsenal, the library of St Geneviève, the City Library, and the libraries of the Chamber of Peers, the Chamber of Deputies, the Institute, and the University. The libraries of the departments are two hundred and fifty in number, exclusively of those which are specially annexed to learned bodies, to establishments of public utility, to colleges, and other institutions.

Royal library. The Royal Library of Paris is justly considered as the finest in Europe. It was commenced under the reign of King John, who possessed only *ten* volumes, to which 900 were added by Charles V., many of them superbly illuminated by John of Bruges, the best artist in miniatures of that time. Under Francis I. it had increased to 1890 volumes, and under Louis XIII. to 16,746. In 1684 it possessed 50,542 volumes; in 1775 it amounted to 150,000; and by 1790 it had increased to about 200,000. At present it contains about 700,000 printed volumes, and 80,000 manuscripts. In 1667, Louis XIV. having ordered all the medals and curiosities contained in the royal residences to be collected together, caused them to be deposited in the library. Learned antiquarians, sent into foreign countries, augmented this collection; rare and precious objects were successively acquired; and the library at present possesses the richest and most varied collection that exists in Europe. The cabinet of engravings, also founded by Louis XIV., is composed of paintings on vellum, designs, and an immense collection of prints and maps, from the discovery of engraving to the present time. It contains 1,400,000 prints or engravings, and 50,000 maps and charts.

The Royal Library is at present divided into the following departments: viz. 1*st*, printed books; 2*d*, manuscripts, charters, and diplomas; 3*d*, coins, medals, engraved stones, and other antique monuments; 4*th*, engravings, including geographical charts and plans. These four departments form four distinct establishments, which, by their importance and the richness of their treasures, exceed every thing of the kind that is to be found in other countries. It is indispensable that the library should every year make the acquisition either of foreign books or of French works in which it is deficient; and it is equally obliged to purchase manuscripts, prints, charts, and medals. A decree of 1556, which fell into desuetude during the troubles of the Fronde, but was renewed in 1689, imposed on publishers the obligation of furnishing to the Library of the King copies of all works printed by privilege; and each copy required to be bound. At present the law prescribes the deposit of copies of all books printed; but the other condition is dispensed with. In consequence of this privilege, the Royal Library receives annually about 9000 volumes stitched; and the number of foreign books sent to it, or acquired by purchase, may be estimated at from 2000 to 3000 volumes. Now, as the price of the binding of each volume is, on an average, three francs, it follows that a sum amounting to about 36,000 francs, or L.1450, would be necessary, every year, to defray the expense of binding alone. But as the funds have for many years been insufficient to meet the whole of this expense, the library has at present more than 120,000 volumes stitched or in boards, and of these there are about 80,000 which urgently require binding. There are likewise 15,000 manuscripts which either require to be bound, or of which the binding should be renewed.[1]

The additions from the Vatican Library, selected by the French commissioners in 1797, were particularly valuable, amounting to 501 manuscripts. Of these, twenty were Hebrew; forty Syriac; nineteen Coptic; eleven Chinese; 133 Greek, amongst which were the celebrated *Codex Vaticanus* of the Septuagint; 176 Latin, including the famous Virgil of the seventh century, Terence of the tenth, Horace of the eleventh, Cæsar of the twelfth, Plautus of the eleventh, Pliny of the tenth, and Ovid of the twelfth centuries; besides many other manuscripts illustrative of the history of the ninth and tenth centuries. Numerous manuscripts in modern languages were also seized in virtue of the compulsory treaty of Tolentino, particularly the Commedia of Dante, transcribed by Boccacio, the Arcadia of Sannazaro, Michel Angelo's letters, and also those of Henry VIII. and Anne Boleyn; besides 136 early printed books, thirteen Etruscan vases, and 737 ancient coins. To these must further be added the manuscripts collected by the French in other parts of Europe, to which their victorious eagles had penetrated. But the events of 1814 and 1815 were followed by as complete a restitution of the literary treasures as of the works of art acquired by right, or rather by abuse, of conquest. Of the contents of this magnificent, nay matchless collection, it would far exceed our limits to give any details, or even to enumerate the choicest articles. It is rich in every branch and department, unique in some, scarcely surpassed in any, unrivalled in all taken together. Of books printed on vellum, it contains at once the finest and most extensive collection in the world.[2] Excepting on Sundays and holidays, the Royal Library is open daily, from ten until two o'clock; every book is brought that is required; and literary men of known respectability are permitted to take books to their own residences. The annual expense of the establishment is 274,000 francs, or nearly L.11,000 sterling, which is provided for in the budget. The principal librarian is the celebrated Hellenist, M. Letronne, with the title of director-president; the conservators, or keepers, are MM. Van-Praët, Magnin, Champollion-Figeac, Hase, Silvestre de Sacy, Raoul-Rochette, Thevenin, and Jomard, all men of distinguished eminence. The actual administration of the library is conducted in conformity with the principles and rules prescribed in an *Ordonnance du Roi*, dated 26th March 1833.[3]

There is no complete catalogue of this vast collection. That of Labbe, printed in 1653, in 4to, treats of some manuscripts, which are divided into historical and chronological, biblical and theological, epistolary and diplomatic, technical and philological. Anicetti Mellot's catalogue of the manuscripts in the Royal Library was printed at Paris, 1739–1744, in four vols. folio. The first volume contains the oriental manuscripts; the second, the Greek manuscripts; the third and fourth comprise those in the Latin language. The catalogue of the printed books, arranged by Sallier Boudot, in six vols. folio, comes down only to the year 1753. Besides these, there are notices and extracts of the manuscripts in the Royal and National Libraries, Paris, 1787–1804, in seven vols. 4to, and a catalogue of the Sanscrit manuscripts in the former collection, by Hamilton and Langlès, Paris, 1807, 8vo. There is no classed catalogue.[4]

The Mazarin library. This library was founded by Cardinal Mazarin.

---

[1] See *Reponses aux Questions adressées au Gouvernement François sur les Bibliothèques*, Appendix to Report on the British Museum, pp. 525, 526.

[2] The number of books printed on vellum, contained in the Royal Library at Paris, amounts to 1467, exclusively of those restored in 1814 and 1815. The total number of books of this sort extant does not exceed 2700. Lord Spencer's collection, which is the richest in this country, contains only 108. (Van-Praët, *Catalogue des Livres imprimés sur Velin de la Bibliothèque du Roi*. Paris, 1822, in six vols. 8vo.)

[3] *Ordonnance du Roi, et Règlement concernant la Bibliothèque Royale, 26 Mars* 1833. Appendix to Report on the British Museum, No. 13, p. 405, et seq.

[4] Le Prince, *Essai Historique sur la Bibliothèque du Roi*, Paris, 1782; Horne, *Introd. to Study of Bibliography*, vol. ii. p. 567, et seq.

formation of it was intrusted to the learned Gabriel Naudé, who, having first selected all that suited his purpose in the booksellers' shops in Paris, travelled into Holland, Italy, Germany, and England, where the letters of recommendation of which he was the bearer enabled him to collect many very rare and curious works. In 1648, this collection consisted of 40,000 volumes, and was already a public library, though that of the king did not become one until 1737. Cardinal Mazarin by his will bequeathed it to the college which he founded, and which, until the epoch of the Revolution, bore the name of the founder. At present it contains 90,000 printed volumes, and 3437 manuscripts. It is remarkable for a great number of collections containing detached pieces, and small treatises, which date as far back as the fifteenth century, and exist nowhere else; nor has any other library so complete a body of the ancient books of law, theology, medicine, and the physical and mathematical sciences. It also possesses a most precious collection of the Lutheran or Protestant authors. In one of the halls are placed models in relief of the Pelasgic monuments of Italy and of Greece; in another is a terrestrial globe, eighteen feet in diameter, formed of plates of copper, and executed by order of Louis XVI. This monument, which is unique in Europe, is unfortunately not finished; a sum of 25,000 francs (L.1000) would be necessary to provide it with the requisite circles. The Mazarin Library is habitually frequented by more than an hundred readers. It is supported by an annual grant of about L.1400, provided for in the budget.[1] M. Petit-Radel is the principal librarian.

Library of the Arsenal

This library, founded by the Marquis de Paulmy, formerly ambassador of France in Poland, was, in 1781, acquired by the Count d'Artois, who conjoined with it nearly the whole of the library of the Duke de Valière. It consists of more than 175,000 volumes, of which about 6000 are manuscripts. It possesses the most complete collection extant of romances, since their origin in modern literature; of theatrical pieces, or dramas, from the epoch of the moralities and mysteries; and of French poetry since the commencement of the sixteenth century. It is less rich in other branches, but it has all works of importance, and, in particular, contains historical collections which are not to be found elsewhere. The library of the Arsenal has always attracted the attention of the learned from all parts of Europe. It is constantly frequented by more than sixty readers, who there apply themselves to scientific and literary researches. The annual grant for its support is 36,000 francs, or L.1440. M. Charles Nodier is principal librarian.[2]

Library of St Geneviève.

The foundation of this library dates as early as the year 1624, when Cardinal de Rochefoucauld, having reformed the Sainte-Geneviève, made it a present of 600 volumes. In 1687, the abbey had already 20,000 printed volumes, and 400 volumes of manuscripts. In 1710, Letellier, archbishop of Paris, bequeathed to it all his books. At the epoch of the Revolution it possessed 90,000 printed volumes and 3000 manuscripts; at present it contains 160,000 volumes and 3500 manuscripts. In it may be found all the academical collections, and a complete set of Aldines; it is particularly rich in historical works; and its most remarkable manuscripts are Greek and oriental. Its typographical collections of the fifteenth century are not more valuable for their number than the high state of preservation in which they are found. This fine library is daily frequented by upwards of two hundred persons, of whom more than a half are students in the different faculties. It is supported by an annual grant from the public treasury of 40,500 francs, or upwards of L.1600. The principal librarian is M. de Lancy.[3]

The City Library contains 50,000 volumes, and is supported by a grant of 7500 francs from the funds of the municipal council. The library of the Chamber of Peers contains 16,000 volumes, and has allotted to it a sum of 10,000 francs for the purchase of books and to defray the expense of binding. The library of the Chamber of Deputies contains 50,000 volumes, and receives annually a sum of 12,000 francs for the same objects. The University Library, which is placed in the buildings of the Sorbonne, consists of 40,000 volumes, and is very useful to the students of the different faculties, who frequent it in the intervals between the lectures or prelections. It expends annually a sum of about 1800 francs.[4]

The foundation of the library of the Institute was the old City Library (*Bibliothèque de la Ville*), which consisted of scarcely 20,000 volumes. At present this excellent and useful collection amounts to nearly 80,000 volumes. It is not yet complete in any department; but it nevertheless exhibits the best possible selection of the principal works in all the important branches of human knowledge; and it may be truly said that it is kept up to the actual state of science and learning. In the acquisitions which are made, the object is not to search for rare editions, but to obtain such as possess some peculiar merit. Academical collections of all kinds and of all countries, magazines and journals of science and literature in all languages, are to be found in it in greater number than any where else. The library increases daily. Numerous works are presented to the Institute, which, on its part, is constantly making new acquisitions; and the premises allotted for its accommodation have become insufficient to contain its accumulations. This collection is reserved for the members of the five academies of which the Institute is composed; but all strangers presented by them are admitted, and it is *de facto* public. As it is open every day during seven hours, the service therein is more severe than in the other libraries, which are only open four hours, and enjoy vacations. The number of books has been quadrupled since the institution of the library, and yet the number of the conservators and assistants remains the same. The annual expense of the establishment, though arranged with the strictest economy, amounts to 46,500 francs, or about L.1860.[5]

The provincial libraries of France, as they are supported at the expense of the different cities, are naturally placed under the immediate direction of the mayors and municipal councils; but they are not the less on that account under the superintendence of the superior authority of the minister of public instruction. Their number, as already stated, exceeds 250, exclusively of those attached to societies, colleges, and other institutions. Amongst the most considerable are those of Bordeaux (115,000), Lyons (100,000), Aix (75,000), Besançon (56,000), Amiens (48,000), Versailles (40,000), Marseilles (35,000), Toulouse (30,000), &c. The catalogue of the manuscripts in the library of Lyons, 1518 in number, is one of the most interesting which has issued from the French press (Paris et Lyon, 1812, in three vols. 8vo). The preliminary disquisition contains notices of the ancient libraries of Lyons; the historical essay on manuscripts contains a neat account of the materials anciently used in writing; the biography of writers who have treated of the subject, though brief, is worthy of attention; and the manuscripts are classed and described with equal judgment and learning.[6]

The number of public libraries in Spain is much greater than has commonly been supposed; nor have the science and literature of that country sunk to such a state of depression as some have been pleased to represent. Few nations, it is true, have ever been doomed to pass through so long and dreary a course of misgovernment; in none have bad laws corruptly administered, and a system of civil polity at variance with every sound principle, done more to cramp the energies and debase the general character of the people. But in spite of the evils which have thus been entailed upon her, Spain is by no means the degraded and benighted country which many have been led to suppose. Her scientific and literary institutions are respectable; several of her establishments are admirable; and some of her collections are unique. The very extravagance and absurdity of her fiscal regulations and expurgatory prohibitions have served to defeat their own operation; and the contrabandistas have ministered to those wants which, under a better and more healthy system, would have been supplied by the regular dealer.[1] This applies to books as well as to other articles; for where there is a demand, no law can prevent the supply, though it may change the direction in which it flows. Hence the quantity of books of every kind in general circulation has at all times been much greater than persons unacquainted with the real state and condition of that country could have imagined. But our business here is with the public and permanent collections of Spain, which are, the Royal Library at Madrid, the library of the Escurial, and the libraries of the provinces.

There are in Madrid four public libraries, which are constantly open from nine in the morning until two in the afternoon, holidays excepted. Of these, the principal is the *Biblioteca Real*, which was, several years ago, removed to a building erected for the purpose in the square beside the palace. This noble collection is open to all, as far at least as the printed books are concerned. The reading-tables are placed in three spacious apartments, corresponding to as many sides of the edifice, which is built round a court, with a fine stair-case in the centre; in the middle of these rooms are rows of tables provided with writing materials and chairs; and against the walls are the book-shelves, numbered and tastefully ornamented. The catalogues are kept in a small room apart, where there are two or three persons in attendance to answer the inquiries of the stranger, and to furnish him with the number and shelf where any particular work may be found. The service of the library is excellent. The principal attendants, ten in number, are respectable literary men, who find here a maintenance, and leisure to follow their different pursuits. The Royal Library contains 200,000 printed volumes, and from 4000 to 5000 manuscripts, amongst which are many valuable Greek, Latin, and Arabic manuscripts, and unedited works, chiefly Spanish. The establishment of the library consists of one principal librarian, D. Joaquin Patiño, six keepers, and the ten attendants already mentioned. The *Monetario*, or cabinet of medals, is arranged in an elegant and beautiful apartment, and contains an unrivalled collection of Celtic, Phœnician, Carthaginian, Greek, Roman, Gothic, Arabic, and modern coins and medals, in excellent preservation. "Le cabinet des médailles de Madrid," says M. Faure, "est sans doute le plus remarquable de l'Europe. Tandis que Paris, qui l'emporte si incontestablement sur la capitale des Espagnes par les monumens des arts et de l'antiquité, n'a que cent mille médailles dans sa collection, il y en a cent quatre-vingt-trois mille dans celle de Madrid: cent cinquante mille sont classées dans l'ordre le plus parfait; trente-trois mille seulement restent à classer. Ces preuves matérielles du passage des Celtes, des Tyriens ou Phéniciens, des Carthaginois, des Romains, des Vandales, des Suèves, des Alains, des Goths, des Maures sur cette malheureuse terre qu'ils se sont arrachée les uns aux autres, réconcile avec les Espagnols, dont on a d'ailleurs tant d'occasions d'accuser l'indifférence. On trouve dans cette collection précieuse de quoi applaudir au zèle de ceux qui l'ont formée et de ceux qui l'entretiennent avec tant de soin."[2] A still more recent traveller, speaking of the *Biblioteca Real*, says, "It is one of *many* institutions which awaken the admiration of the stranger in Spain, as being at variance with the pervading decay."[3] The only catalogue that has been printed is one of the Greek manuscripts, by D. Juan Yriarte (Madrid, 1769, folio); a work rarely to be met with, the king of Spain having reserved the whole impression for presents.

Library of the Escorial.

The convent of the Escorial, situated upon the southern declivity of the Guadarrama chain, about half way up the mountain, owes its existence to a vow made by Philip II. during the crisis of the battle of Saint-Quintin. It derives its name from San Lorenzo del Escorial,[4] to whom it was dedicated, and has been often described. At present we have only to do with the literary treasures contained in this magnificent edifice. In the library of the Escorial there are about 130,000 printed volumes, and between 4000 and 5000 manuscripts, of which 567 are Greek, 67 Hebrew, and 1800 Arabic. The Arabic manuscripts were originally much more numerous;[5] but a large proportion of them was consumed by the fire which, in 1671, destroyed a great part of the library, and all that remains is the number just stated. Besides these, which are extremely curious, there are detached manuscripts of great rarity and value, particularly one of the Four Gospels, written on 160 leaves in gold letters, and supposed to be of the tenth century; a treatise by St Augustin, *De Baptismo Parvulorum*, said to be in his own handwriting; the original works of St Teresa; and a parchment roll containing an original Greek manuscript by St Basil. The books are placed, whimsically enough, with their backs to the wall, so that the edges of the leaves are turned outwards, and the titles of the works written thereon. This was the practice of Arias Montanus, whose library formed the basis of that of the Escorial; and the same absurd method has continued to be followed for the sake of what is called uniformity. The library of the Escorial was founded by Charles V.[6] There is no printed catalogue of the books; and that of the learned Casiri includes only the Arabic manuscripts rescued from the conflagration of 1671, with a few others subsequently acquired. This catalogue, however, is particularly valuable, inasmuch as each manuscript is not only enumerated, but its age and the author's name, when known, are also given, together with occasional extracts both in the original Arabic and in the Latin language.[1]

[3] *A Year in Spain*, vol. i. p. 243, et seq. London, 1831, in 8vo.

[4] *Escorial* is formed from the Spanish word *escoria*, signifying *dross*. It is commonly applied to all places where there are old or exhausted mines.

[5] In a fortress belonging to the emperor of Morocco, there were found 4000 Arabic manuscripts, which were carried to Paris for sale; but not being prized in that capital, they were transported to Madrid, where about 3000, including the most valuable, were selected for the library of the Escorial by order of Philip II.

[6] It is not a little singular, that in the return of the "Public Libraries and Archives of Spain," made to Lord Palmerston by Mr

Provincial libraries.

The number of provincial libraries in Spain is considerable. The more extensive and important are those of Toledo (30,000), Salamanca (24,000, with 1500 MSS.), Santiago University at Coruña (17,307, with forty-one MSS.), and Valladolid (13,000). But at Malaga, Peruel, Seville, Murcia, Lugo, Cervera, Oviedo, Palma, and some other places, not to mention the library of the Asturian Institute, and that of the Junta of Commerce at Coruña,[2] are collections of books varying from 3000 or 4000 to between 9000 and 10,000 volumes each.

Italian libraries.

Italy is rich in literary institutions of all kinds, particularly in noble collections of books and manuscripts. Indeed there is scarcely a city in the whole peninsula without its library; and many of those which are considered as small collections in that country would be differently estimated in most others. It is to be regretted, however, that of some of the larger collections, as for instance the Ambrosian Library at Milan, no adequate account can be given, owing to the inaccessibility of the necessary materials.

Library of the Vatican.

Amongst the libraries of Italy, that of the Vatican, at Rome, stands pre-eminent, not more for its grandeur and magnificence, than for the inestimable treasures with which it is enriched. The origin of this library is attributed by some to Pope Hilarius, who, in the fifth century, founded one in the Lateran Palace. But although it is probable, that, even prior to that period, the Roman church must have possessed a considerable stock of books for the use of its clergy, yet it may be supposed that the pontiffs were too much occupied with the dangers and difficulties of the times, to have either the leisure or the means necessary for the formation of libraries. That a good many volumes, however, had been collected at an early period, seems pretty certain; nor is it less so, that Pope Zacharias considerably augmented their number about the middle of the eighth century. Still Nicholas V., learned himself, and a distinguished patron of letters, is justly considered as the founder of the Vatican Library; for of the collections of his predecessors little remained when he ascended the papal throne, the books having been either lost or destroyed by the frequent removals from Rome to Avignon, and from Avignon to Rome. This pontiff added above 5000 manuscripts to the original collection, placing all in the Vatican; and Calixtus III. is said to have enriched it with many volumes saved from the libraries of Constantinople, when that city fell into the hands of the Ottomans. From this period, it continued to increase in a regular progression, receiving almost every year vast additions, sometimes even of whole libraries, owing not only to the favour of the pontiffs and various princes, but also to the well-directed zeal of its librarians, many of whom have been men of eminent talents as well as of high rank and extensive influence.[3] Under the reign of Pope Urban VIII. a most valuable addition was made by the purchase of the library at Heidelberg, belonging to the Elector Palatine; and those of the Dukes of Urbino, and Christina queen of Sweden, were likewise annexed to the collection in the Vatican. The same pontiff despatched Leo Allatius into Germany for the purpose of selecting the most valuable books to be sent to Rome;[4] and by these acquisitions, conjoined with the liberality of subsequent popes, the Vatican Library became the richest perhaps in the world, at least in manuscripts, before the most valuable of these were conveyed to Paris in the year 1797.

This magnificent library consists of three divisions or compartments, besides the vestibule; the ante-room, the double gallery, and the great saloon or hall. The vestibule contains Chinese works relating to geography and chronology, together with two columns bearing ancient inscriptions. The ante-room is appropriated to the two keepers of the library, and the secretaries, or rather interpreters, seven in number, who can speak the principal languages of Europe, and who attend for the convenience of learned foreigners. In this apartment are also accommodated those engaged in translating from the Hebrew, Arabic, Syriac, Greek, and Latin languages; and it is open daily for the use of students, Thursdays and holidays alone excepted. Passing from the ante-room, the visitant enters a double gallery of two hundred and twenty feet in length, which strangers at first conceive to be the whole library; but at its extremity there opens upon the astonished visitant, in almost interminable perspective, another gallery, which, according to some, exceeds a thousand English feet in length,[5] and forms the great saloon or hall of the Vatican, with various rooms and cabinets annexed. These galleries and apartments, all vaulted and painted with varied effect by painters of different eras and talents, constitute the receptacle of this noble collection. The books are all kept in close cases; and in the Vatican the stranger seeks in vain for that imposing display of volumes which he may have seen and admired in other libraries. The number of these has never been accurately stated; some confine it to 200,000, others raise it to 400,000, and some swell it to more than 800,000,[6] whilst not a few, carrying exaggeration into the other extreme, reduce it as low as 90,000, and even below 50,000, or the number of the manuscripts. This monstrous discrepancy has been occasioned partly by the want of a catalogue, and partly also by the books being kept in close cases; but when we take into view the successive accumulations of so many centuries, and consider the number of entire libraries which have, at different times, been combined with this vast collection, we shall not probably err in estimating the total number of printed volumes at upwards of 500,000, amongst which is a choice collection of books printed in the fifteenth century.

But the superiority of this library consists not so much in the quantity of printed books it contains, as in the number of its manuscripts, which are said to exceed 50,000.[7] Some of these manuscripts are of the highest antiquity, such as

---

Villiers, and printed in the Appendix to the Report on the British Museum (p. 511, et seq.), no notice whatever is taken of the library of the Escorial; whilst the regulations of a provincial library (that of the Junta of Commerce at Coruna) are inserted at full length.

[1] *Bibliotheca Arabico-Hispana Escurialensis*, Madrid, 1760–1770, in two vols. folio.

[2] See Appendix to the Report on the British Museum, pp. 514, 515, et seq.

[3] Eustace, *Classical Tour through Italy*, vol. ii. pp. 57, 58, London, 1817, in 8vo.

[4] Allatius wrote in Italian a tract on the conveyance of the Palatine Library to Rome, which tract was translated into Latin by Quade, and published at Gryphiswald, 1708, in 4to.

[5] *Rome in the Nineteenth Century*, vol. ii. p. 383, Edinburgh, 1822, in 8vo. Mr Eustace (*Classical Tour*, vol. ii. p. 56), makes the great hall only 800 feet in length, which seems more likely to be correct.

[6] Eustace, *Classical Tour*, vol. ii. p. 57.

[7] The number of manuscripts, like that of printed books, has been variously stated. In Starke's Guide (art. *Biblioteca Vaticana*, c. vii.) it is set down as "forty thousand." The authoress of *Rome in the Nineteenth Century* (vol. ii. p. 380) informs us that the col-

that of Virgil of the fifth century, written in capital letters, and illuminated with miniatures, representing the Latins and Trojans in the respective dresses of their own times; a Terence equally ancient; another of the ninth century, illuminated with ancient masks; a Greek Bible of the sixth century, written in capital letters, according to the Septuagint version, and from which all the subsequent copies have been taken; and the Gospels of St Luke and St John, written in the tenth century, and bound in ivory. Amongst the rare manuscripts in this splendid collection may also be mentioned, several Hebrew, Syriac, Arabic, and Armenian Bibles; a very large Hebrew Bible presented to the library by the Duke of Urbino, for which the Venetian Jews offered its weight in gold; a Greek manuscript containing the Acts of the Apostles, written in gold letters, and presented to Innocent VIII. by the queen of Cyprus; a Missal written in 1118; another adorned with miniatures by Giulio Clovio, the scholar of Giulio Romano, and the finest miniature-painter of his time; a large Breviary, ornamented with beautiful miniatures, and presented to the library by Matthias Corvinus, king of Hungary; the Annals of Baronius, in twelve volumes, written with his own hand; several volumes of Ecclesiastical History, by the learned Onofrio Panvinio; a Martyrology, curious on account of its antiquity and its miniatures; a manuscript of Pliny, with five miniatures of animals; a beautiful copy of Tasso's *Gierusalemme Liberata;* a Dante adorned with exquisite paintings, begun by the Florentine school, and finished by Giulio Clovio; a treatise on the Seven Sacraments by Henry VIII. of England; several Letters between that royal wife-killer and Anne Boleyn; several papers written by Martin Luther; and manuscripts on Egyptian papyrus. This library possesses a very fine cabinet of medals, which was carried off by the French, but compulsorily restored, after the events of 1814 and 1815. There is also attached to it a chamber filled with a fine collection of prints, to which admission can only be obtained by a particular order; and in another are deposited the secret archives of the Vatican, to which, of course, there is no admission at all. A cardinal is always nominal librarian; but the actual head of the Vatican Library is the celebrated Angelo Maio, so distinguished for the discoveries which he has made by deciphering the palimpsest or rescribed manuscripts.[1] In fine, there is every reason to conclude that the riches of this department have by no means been fully explored, and that an abundant harvest yet awaits future inquirers who to the requisite skill join inflexible perseverance.

Othe b. arie f Rom.

The other libraries at Rome, of sufficient importance to deserve notice, are the Barberini collection, containing about 50,000 printed books, and several thousands of manuscripts; the Colonna Library, distinguished for about four hundred volumes of books and engravings, printed or executed in the fifteenth century; and the collection of the Roman College, in which is contained the library and museum of Athanasius Kircher, the German Jesuit, so famous for his misapplied learning and ingenuity, not to add imaginative vagaries, on the subject of Egyptian hieroglyphics.[2]

Ambrosian library.

The Ambrosian Library, notwithstanding its appellation, has no connection with antiquity, and owes its existence entirely to the munificence of Cardinal Federigo Borromeo, nephew of Charles Borromeo, and his successor in the see of Milan. This prelate began to collect books, when a student at Rome; and enlarging his plan as he advanced in age and dignities, he, when raised to the archbishopric of Milan, erected an edifice, placed in it his collection, and opened it to the public under the title of *Bibliotheca Ambrosiana.* This library contains between 40,000 and 50,000 printed volumes, and upwards of 15,000 manuscripts; and there is annexed to it a gallery of pictures, statues, antiques, and medals, comprising many articles of great rarity and value. In the department of manuscripts is a collection of the various works of Leonardo da Vinci, enriched with his drawings and designs: it was presented by a citizen of the name of Galeas Arconati, who generously refused a vast sum for the precious treasure, and, to secure the possession of it to his country, consigned it to the Ambrosian Library as to an inviolable sanctuary. The sanctuary, however, was violated by the French—"di Parigi le vagabonde belve,"—in 1791, who seized the cherished relic of Leonardo's genius, and sent it off to Paris, tumbled and tossed in the common mass of plunder;[3] but what an abuse of victory enabled them to carry off, the fortune of war at length compelled them to restore. The same department also includes a Virgil with annotations by Petrarch, in his own handwriting; a Pliny, a Plato, and a Cicero of the second century; and a Josephus, on papyrus, written on both sides of each leaf. It is to be regretted, however, that the manuscript treasures of this collection have not been particularly described. Signor Angelo Maio, now librarian of the Vatican, formerly held the same office in the Ambrosian Library at Milan, and there commenced those researches relating to palimpsest or rescribed manuscripts, which have issued in the recovery of some ancient remains believed to have been for ever lost, and entitled this ingenious and indefatigable scholar to the lasting gratitude of the learned.[4] The other libraries of note in the Lombardo-Venetian territory are those belonging to the universities of Pavia and Padua. These libraries contain about 50,000 volumes each, and are open ten months in the year, four hours in winter and six in summer, every day excepting Wednesdays, Sundays, and holidays.[5]

Bologna library.

Bologna, celebrated for its scientific and literary institutions, and its academy for the encouragement and promotion of art, boasts likewise a great public library. This extensive collection, consisting of above 100,000 printed volumes, and from 4000 to 5000 manuscripts, is contained in the Manfredi Palace, and is open to the public six days in the week. In the same palace are, an observatory, furnished with an excellent astronomical apparatus; a large

---

lection amounts to "*upwards* of thirty thousand." And Mr Eustace says that it is supposed to exceed "fifty thousand." The last estimate, we have reason to believe, is the nearest to the truth. As to the authoress of *Rome,* she evidently writes on a subject which she had not examined. Vasi, after describing the rarities of the Vatican, speaks of it as "arrichita collo spoglio di moltissime librerie di Europa, e di altrove ancora; tanto che in oggi non vi è una simile." (*Itinerario di Roma,* p. 503, Rome, 1777.)

[1] The palimpsest or rescribed manuscripts are those in which the ancient writing has been totally or partially obliterated, to make way for later compositions, merely to save parchment. From manuscripts thus barbarously manipulated, Signor Maio has recovered part of Cicero's celebrated treatise *De Republica;* the correspondence between Fronto and Marcus Aurelius, before and after the latter became emperor; a fragment of an oration by Q. Aurelius Symmachus, with the supplements of two other orations; and the supplement to the Ulpian Commentaries.

[2] Vasi, *Itineraire,* p. 552.

[3] Eustace, *Classical Tour,* vol. iv. p. 27, et seq.

[4] No account of this collection, that we are aware of, has appeared in recent times. Oppicelli's *Monumenta Biblioth. Ambros.* was printed at Milan in 1618, 8vo; and Boscha *de Orig. et Stat. Bibl. Ambros.* was published in the ninth vol. of Muratori's *Thesaurus,* part vi. An *Oratio de usu et fructu librorum Biblioth. Ambros.* appeared at Leyden in 1623, 8vo.

[5] *Bolletino Statistico ed Economico di Milano,* 1833.

chemical laboratory; a cabinet of natural history; an experimental cabinet, with all kinds of instruments for physical operation; two halls of architecture, civil and military; a gallery of antiquities, another of statues, and a third of paintings; with halls of anatomy and midwifery.[1] An establishment so complete in itself, and so concentrated for all the purposes of education and study, is nowhere else to be found. The other universities of the Roman states are also possessed of considerable collections of books. That of Perugia, founded as early as 1307, has a library of 30,000 volumes; that of Ferrara, founded at a much later period, has a library containing no less than 80,000 volumes; and the three universities of Macerata, Urbino, and Camerino, have each libraries, though upon a smaller scale.[2]

Florentine libraries.

The public libraries at Florence are the Mediceo-Laurenzana, or Laurentian; the collection bequeathed to the public by Magliabechi, by whose name it is distinguished; the Marucelliana; the Riccardiana, which was purchased not long since of the Riccardi family; and the library of the *Belle Arti*, containing the books which were taken out of the suppressed convents.

Mediceo-Laurentian library.

The Mediceo-Laurentian Library, which is contained in the convent annexed to the church of San Lorenzo, was commenced by Cosmo de' Medicis, the father of a line of princes whose name and age are almost synonymous with the restoration of learning. "His credit," says Gibbon, "was ennobled into fame; his riches were dedicated to the service of mankind: he corresponded at once with Cairo and London; and a cargo of Indian spices and Greek books were often imported by the same vessel."[3] As the natural disposition of this princely merchant led him to take a very active part in collecting the remains of classical antiquity, so his wealth and extensive commercial intercourse enabled him to gratify his taste to the fullest extent. He enjoined his friends and correspondents, as well as the missionaries who travelled into remote countries, to search for and procure ancient manuscripts in every language and upon every subject. He availed himself of the services of the most learned men, his contemporaries; and the situation of the eastern empire, then falling into ruins, afforded him an opportunity of obtaining many valuable works in the Hebrew, Greek, Chaldaic, Arabic, and Indian languages. After the death of Cosmo, his son pursued the same object with steady perseverance, and added considerably to the treasures which had been accumulated by his father. But although the ancestors of Lorenzo de' Medicis had laid the foundation of the Laurentian library, the honour of raising the superstructure belonged to Lorenzo himself, whose assiduity and liberality in enlarging his collection of books, manuscripts, and antiquities, were unbounded. To this object his time and his fortune, exceeding that of princes, were equally devoted. Shortly after the death of Lorenzo, however, this matchless collection was dispersed by the French troops under Charles VIII. in resentment of some imaginary insult; and in the perpetration of this sacrilegious deed, "the Gallic herd" were joined by the Florentines themselves, who openly carried off, or secretly purloined, whatever they could discover that was most rare, curious, and valuable. The library, however, was subsequently restored by the perseverance and liberality of Leo X. who caused it to be removed to Rome; but it was reconveyed to Florence by his successor Clement VII., who, by a bull dated the 15th of December 1532, made provision for its future security.[4] This library, the noblest monument which the Medicis have left of the glory of their line, contains about 100,000 printed volumes, and 9000 manuscripts, many of them of great rarity and value. The latter have been described in a catalogue of eleven folio volumes, undertaken and executed by the learned Bandini, formerly librarian, at the suggestion of the Emperor Francis I. who presented him with a sum of money towards the expense, and made him promises of further assistance, which, however, were rendered unavailing by the death of that sovereign.[5] The Laurentian Library is under the charge of Signor del Faria, who receives annually 396 scudi, or about L.94 sterling.

Magliabechian library.

Magliabechi, from being a servant to a dealer in vegetables, raised himself to the honourable office of librarian to the Grand Duke of Tuscany at Florence, and became one of the most eminent literary characters of his time. The force of natural talent overcame all the disadvantages of the humble condition in which he had been born, and placed him in a situation to make his name known and respected. But he endeavoured to deserve still better of his countrymen, by presenting them, some time before his death in 1714, with his large and valuable collection of books, together with what remained of his fortune, as a fund for its support. This constituted the foundation of the Magliabechian Library, which, by the subsequent donations of several benefactors, and the bounty of some of the grand dukes, was so much increased both in number and value, that it may now vie with some of the most considerable collections in Europe. The books printed in the fifteenth century have been described by the Abbate Follini, the present librarian, who dedicated his catalogue[6] to Ferdinand III.; but there is no general catalogue of the library. It is particularly rich in the early productions of the Italian press, which are described alphabetically, with much accuracy of detail; and to these are added brief notices of the lives of the different authors, derived from the most authentic sources. The Magliabechian Library is supposed to contain 150,000 printed volumes, and 9000 manuscripts; and the public are admitted to it every day of the year, except on Sundays and festivals. The Librarian has an annual stipend of 240 scudi, but not more than 100 scudi are expended annually in the purchase and binding of books.[7] The further extension of this collection is, therefore, effectually precluded, otherwise than by donations.

Other Florentine and Tuscan libraries.

The Marucellian, containing 50,000 volumes, is also under the charge of Signor del Faria of the Laurentian, and it is open every Monday, Wednesday, and Friday. The Riccardi collection is managed by the Canon Bianchi and a sub-librarian; it contains 26,000 volumes. The collection of the *Belle Arti* consists of 11,000 volumes, and is open to the public every Tuesday, Thursday, and Saturday. The disbursements on account of these various libraries are made by their respective librarians, under the control of the minister of the interior; the sums expended, however, are but trifling. The libraries of the universities of Pisa and Sienna are valuable, each of them possessing about 50,000 volumes, to which an annual addition of books to the value of 100 scudi is respectively made. In almost all the provincial towns of Tuscany, there are also to be found public libraries more or less extensive, which are all placed under the control of the communal magistrates.[1]

Neapolitan libraries. There are five public libraries at Naples, viz. the Royal Library, the Brancacciano Library, the library of the University, the library of the Military Staff, and the library of the Monks of St Jerome. The Royal Library contains about 300,000 printed volumes and 6000 manuscripts; the University possesses 50,000 volumes; the Convent of St Jerome has an equal number; the Brancacciano contains 10,000; and the Military Staff has 10,000. The public have free admission to read in these libraries, but no books are allowed to be taken away. They are all open every day, for about six hours, excepting on holidays, when they are closed. The expenses of the Royal Library are included in those of the Museum, of which it forms part. It is entitled to two copies of all books printed in the kingdom of Naples; and 4000 ducats (L.687) are annually appropriated to the purchase of foreign books. The expenses of the library of St Jerome are defrayed out of the funds of the Convent to which it belongs; but, like the Brancacciano, the Military Staff, and the University Libraries, it is entitled to one copy of every book printed in the kingdom of Naples. This collection is singularly rich, chiefly in ancient books. There are no public libraries in any of the provincial towns, excepting Foggia and Lucera; but in every diocese there is a library belonging to the see, to which, upon application, admission may at all times be readily obtained.[2]

Libraries of Venice, Turin, &c. The remaining libraries in Italy are numerous, and some of them considerable, particularly those of Venice and Turin. In the library of St Mark at Venice, there is a copy of the Gospel of the evangelist of that name, which is affirmed to have been written by himself. This library was founded in the fourteenth century, the collection having been begun by Petrarch, who bequeathed his books to the republic. Cardinal Bessarion, by his will, added to the library the curious collection of manuscripts which he had formed in Constantinople, in Egypt, and in Greece; and further additions were subsequently made to it by other cardinals. The library of St Mark is deposited in two apartments, one of which is appropriated to manuscripts, whilst the other contains the printed books. Though small when compared with other libraries of the Continent, this collection includes many rare and valuable articles.[3] The library attached to the university of Turin contains 112,000 printed books, and a rich collection of manuscripts. It is open to the public in general every day except festivals. Connected with the university are several museums, particularly that of Egyptian antiquities, purchased by the king, of Mr Drovetti, which is one of the richest and most valuable in Europe. Attached to the university of Genoa, which now belongs to the king of Sardinia, is a library, consisting of about 45,000 volumes.[4] Several public and private libraries at Padua contain a number of manuscripts; as do also the chapters of Verona, Novara, and Vercelli. From a rescribed manuscript discovered by Niebuhr, the Roman historian, in the collection of the chapter of Verona, was deciphered and published no inconsiderable portion of the Institutions of Gaius, which served as a model to Justinian, or rather to Tribonian, in framing that elementary exposition of principles which is prefixed to the Digest. The library at Mantua is inconsiderable. The library of Messina in Sicily contains a valuable collection of Greek manuscripts, described in a catalogue, printed in the ninth volume of Grævius's *Thesaurus Antiquitatum et Historiæ Siciliæ*.[5]

Libraries of Germany. The libraries of Germany, taking that name in its widest acceptation, are, some of them, of the first order, and many of them extensive and important; but, from the length to which this article has already extended, we must confine our notices exclusively to the principal collections, which we shall describe in the order, not of place or of time, but of their relative magnitude and value.

Imperial library at Vienna. The Imperial Library at Vienna is perhaps inferior only to that of the Vatican and the Royal Library at Paris, for the rarity and value of its contents. It was founded by the Emperor Frederick III. who spared no expense to enrich it with printed books as well as manuscripts in every language. By the munificence of succeeding emperors, numerous important and valuable accessions were made to the collection; amongst which may be mentioned the large and interesting library of Prince Eugene, and a considerable portion of the Buda Library, founded by Matthias Corvinus, king of Hungary. The Imperial Library occupies eight spacious apartments; and a ninth is appropriated to a very valuable collection of medals and other curiosities.[6] It contains 350,000 volumes of printed books, and 16,000 volumes of manuscripts.[7] The books are disposed according to their sizes, and comprise almost a complete series, exhibiting the origin and progress of the typographic art. The number of works printed in the fifteenth century exceeds 12,000, amongst which are four out of the five *incunabula* on vellum, printed by Pannartz at Rome. Here also is a copy of the Soncino Bible, printed in 1488, by far the scarcest, and perhaps the most valuable of all the impressions; a copy of the first edition of Apuleius, printed in 1469, on vellum, and unique; and a copy of the first edition of Aulus Gellius, printed the same year, on vellum, and also unique. These two treasures were once the property of Cardinal Bessarion, and are comparatively but recent acquisitions of the imperial collection. The Florence Dante of 1481, with the commentary of Landino, and the plates of Baldini from designs by Boticelli, is likewise in this library. This is the finest copy extant, excepting that in Earl Spencer's collection, each of which possesses twenty copperplates.[8] The Cimelia, or remarkable rarities, are twenty-four in number. Amongst these are, a tablet of bronze, containing the original *senatus-consultum* or decree of the Roman senate for the suppression of the Bacchanalians, passed in the year 186 before Christ;[9] *Tabula Peutingeriana*, a travelling map of the Roman empire in the fourth century, on parchment; several palimpsests procured from the monastery of Bobbio; and the great roll of Mexican picture writings, published by Lord Kingsborough. A few of the manuscripts deserve to be mentioned, on account of their singular rarity. Amongst these are, a Mexican manuscript, with coloured figures, on human skin; a manuscript of Livy, of the fifth century, of which a few pages are wanting; a manuscript of St Mark's and St Luke's Gospels, written in gold and silver characters; and a manuscript of Dioscorides, with coloured drawings of plants, written in the fifth century, by order of the Princess Julia Anicia, only daughter of the Emperor Olybrius. This precious manuscript was brought from Constantinople in 1550, by the celebrated Busbequius,[1] ambassador from Charles V. to the Porte, by whom about 300 other Greek manuscripts were collected in the Turkish capital, including a manuscript of Pliny's *Historia Naturalis*, of contemporary date. Besides these there are, in this collection, fragments of Genesis in uncial Greek, the letters silver embossed on purple parchment, richly ornamented with miniature paintings; a fragment on papyrus, containing the decrees of the third council of Constantinople, held in the year 680; *codex clathratus*, or fragments of the most ancient German translation of the Gospel of St Matthew, written in the early part of the eighth century;[2] a German Bible in six volumes folio, richly illuminated, written for the Emperor Wenceslas, in the fourteenth century; a French manuscript of the fourteenth century, written in large letters, according to the ancient orthography, profusely illuminated, and containing the history of Tristan, the celebrated knight of the Round Table; together with many other rare, curious, and interesting manuscripts. The Greek manuscripts in the Imperial Library have been described by Lambecius, Nessel, and Kollarius, whose labours were confined to this class; and in the important and accurate work of Denis may be found an ample account of the Latin, with a few notices of oriental manuscripts, the ages of the different manuscripts being stated where these could be ascertained. Besides the cabinet of medals, there is also attached to the library a superb collection of engravings, consisting of 473 large folio volumes, 510 volumes of different sizes, and 215 folio cartoons. The collection of music contains 6000 volumes, theoretical and practical; and that of autographs exceeds 8000 pieces, classed under the heads of monarchs and princes, ministers and statesmen, poets, philosophers, and men of learning or science, generals and renowned warriors, artists, and others. The sum allowed for the purchase of new books is about L.2000 annually. The Imperial Library is open to the public every day except on Sundays, holidays, and the vacations.[3]

[3] Balbi, in the appendix to his *Essai Statistique*, gives some very extraordinary particulars of the *Archivio Generale* at Venice, to which great attention is paid by the Austrian government. This unparalleled collection contains 8,664,709 stitched quires, divided into 1890 departments, and arranged in 298 apartments. But whether its value corresponds with its magnitude, is a point on which we have been left to our own conjectures. See *Athenæum* for the 19th March 1836.

University, and other libraries at Vienna.

In Vienna, the University Library ranks next to the Imperial Library, but the number of books in it is not stated by Balbi. It received the collections which belonged to the convents suppressed by Joseph II.; and since 1806 it has had a right to a copy of every work printed in Lower Austria. Amongst what are called the private libraries, the most important is that of Military Archives, established in 1801, upon a plan devised by the Archduke Charles. It contains 6626 works on military science and art; twenty large folio volumes of bulletins, gazettes, and journals, with an index; seventy-three atlasses, with about 3000 charts, maps, and plans, of various kinds; and a small collection of manuscript military memoirs, amongst which are those of Montecuculi, who commanded the imperialists opposed to Turenne, and of Prince Eugene. The libraries of oriental literature, of natural history, of the Philharmonic Society, and of the Imperial Archives, are also of great value. In the last are preserved the archives of Venice, and Marino Sanudo's original history of that republic, in fifty-six volumes, which was unknown when M. Daru published his celebrated work. Of the libraries belonging to individuals, the most remarkable are those of Prince Metternich, M. Von Hammer, and Mr Castelli. Von Hammer possesses an unrivalled collection of Turkish manuscripts. Mr Castelli's is a dramatic collection, containing upwards of 10,000 German dramas, original and translated; about 500 manuscripts; 700 portraits of actors, actresses, and dramatists; and an unique collection of play-bills from the year 1600. The total number of libraries, public and private, in Vienna, is forty-five; and even the latter are accessible to students furnished with proper introductions.[4]

Royal library at Munich, &c.

The Royal Library at Munich is the most extensive collection in Germany, containing 500,000 volumes of printed books and 16,000 volumes of manuscripts; thus exceeding the Imperial Library at Vienna by 150,000 printed volumes, and equalling it in the number of manuscripts. From a discourse on the origin and increase of the library at Munich, delivered in 1784, by the Canon Steigenberger, the librarian, and translated into Latin by Vitali, it appears that the Hebrew, Arabic, Syriac, Greek, and Latin manuscripts contained in this library then formed a precious treasure; and, since the period to which this discourse refers, numerous and important additions have been made to all the departments of the collection. The ancient manuscripts relative to the art of music amount to a great number, and are exceedingly curious.[5] A catalogue of the Greek manuscripts in this library, compiled by Ignatius Hardt, was printed at Munich in 1806.[6] The Royal Library is deposited, not in the palace, but in a college formerly belonging to the Jesuits, where it occupies a handsome building. It is open to the public at certain hours each day, Sundays and holidays excepted.[7] Besides the Royal Library, Munich has its University Library, which contains 160,000 printed books.[8]

Royal library at Dresden, &c.

The king of Saxony's library at Dresden contains 300,000 volumes of printed books, besides 150,000 dissertations, and 2300 volumes of manuscripts. The valuable library that formerly belonged to Count Bunau forms part of this noble collection, which is most complete in general history, and in Greek and Latin classic authors. Amongst the printed books are some of the rarest specimens of early typography, including 600 of the Aldine editions, and many on vellum, besides a copy of the first edition of the *Orlando Furioso*, printed by Mazocco, "coll' assistenza dell' autore," in 1516, and other rarities. In the department of manuscripts are, a Mexican manuscript, written on human skin, containing, according to Thévenot, a calendar, with some fragments of the history of the Incas; *Liber de re militari*, on vellum, with superb paintings in fine preservation, presented to an elector of Saxony, by Matthias Corvinus, king of Hungary; the original manuscript of the *Reveries* of Marshal Saxe, bearing at the end that he had composed this work in thirteen nights during a fever, and completed it in December 1733; a fine copy of the Koran, taken from a Turk by a Saxon officer, at the last siege of Vienna, and said to have formerly belonged to Bajazet II.;

[8] A more particular account of this library may be found in Schaden's *Beschreibung der Haupstadt München*, p. 78, 1833, 2d ed.

a Greek manuscript of the Epistles of St Paul, of the eleventh century; and a very fine collection of portraits of the most celebrated persons of the seventeenth century, by Rabel, a French artist, the outlines only having been engraved.[1] An extensive collection of antiquities is preserved, in twelve apartments under the library, below which are eighteen vaulted cellars, stored with a vast quantity of valuable porcelain, partly of foreign, and partly of Dresden manufacture. The expenses of the Royal Library are defrayed by the state. The sum of 2500 dollars, equal to L.375, is allowed yearly for the purchase of books, binding, &c. The only other public library in Saxony is that at Leipzig, which is principally intended for the use of the university of that city; it is under the control of the minister of public worship, and contains 110,000 printed volumes, and 2000 volumes of manuscripts. There are printed catalogues of all the collections at Dresden, excepting those of natural history and of engravings. These libraries are open to the public, except on Sundays and holidays.[2]

Library of Göttingen.

The library attached to the university of Göttingen contains 300,000 printed volumes, and 5000 volumes of manuscripts. But its extent is its least recommendation; for it is not only the most complete amongst the universities, but there are very few royal or public collections in Germany which can rival it in real utility; and if not in Germany, where else? It is not rich in manuscripts, even including the acquisitions which it made from Helmstadt, when the university of that place was dissolved; and many other libraries, as Mr Russell justly observes, surpass it in typographical rarities, and specimens of typographical luxury; but none contains so great a number of really useful books, in almost every branch of human knowledge. This library is mainly indebted for the pre-eminence it has obtained to the labours and exertions of the illustrious Heyne. In the year in which he came to Göttingen as second librarian, the entire control of the library was committed to him, and he became chief. From this moment commenced at once its extension and its improvement. When Heyne went to Göttingen, it already possessed a library of from 50,000 to 60,000 volumes, which, compared with those of most universities, was a considerable collection. At his decease it had, according to the most moderate computation, increased, exclusively of extraordinary acquisitions, to upwards of 200,000 volumes. But this increase of number was its smallest claim to admiration. At the commencement of this period entire departments of learning were wholly wanting; at its close not only were these deficiencies supplied, but the library had become proportionally rich in every department, and, in point of completeness, unrivalled. It would be interesting to trace the manner in which this change was effected; but neither our plan nor our space admits of such details. The system of catalogues appears to be somewhat complete. There are, in fact, four catalogues connected with each other. Every addition to the library is first entered in the *Manual* of the year, in which are concisely written the title and date of the book, and the day of its reception. Then the book is entered with its full title in the *Accession-Catalogue*, which is also commenced with every year, and forms at its close four volumes; the first containing entries of books on theology; the second, of books on jurisprudence; the third, of those on history; and the fourth, miscellaneous works. These two catalogues are intended more particularly for the use of the librarians; the remaining two are for readers. The third of the series is a complete *Alphabetical Catalogue*, in which every book is entered under the author's name, when given, or, when not given, but known, with a reference thereto under the chief word of the title. Every book of which the author's name is not known, is entered under such chief word of title; and, on one side, are also entered the date and form, with reference to the entries of the same book in the Manual and the Accession-Catalogue; on the other is entered the head of the classed catalogue to which the book belongs. Lastly, the book is entered in the *Classed* or *Scientific Catalogue*, according to its subject, and is then placed in that division of the library to which it belongs. The alphabetical catalogue answers the question, whether a certain book is in the library, and where it is to be found; and the scientific or classed catalogue shows what books are contained in the library upon any given subject. Such is a brief account of the mechanism of this very extensive library. A full exposition of it would require the scientific *schematismus* upon which the whole is founded, and would lead us to take a general survey of human knowledge.[3]

Royal library at Berlin.

The Royal Library at Berlin contains 250,000 volumes of printed books, and 5000 volumes of manuscripts. This collection includes works upon almost all the sciences, and in nearly all languages, but it is perhaps most complete in the sciences. Amongst the manuscripts are several Egyptian deeds, written on papyrus, in the demotic or enchorial character, but whether with or without Greek registries, we have not ascertained. Professor Kosegarten, in his first commentation on the Ancient Literature of the Egyptians,[4] has published fac-similes of a considerable portion of one of these, and of the *exordia* of twelve others, with interlinear translations in Latin, according to Dr Young's method of interpretation. The same department also includes several manuscripts of Lacroze, the celebrated author of the Coptic Lexicon, particularly his reply to Bergier, in which he mentions the additions made to the Royal Library, the librarians, the number of books at the time when he wrote, and the curious articles contained in the collection. No complete catalogue has ever, so far as we know, been printed. Heinrick's *Notitia*, printed in 1687, 4to, and his *Pandectæ Brandenburgicæ*, printed in 1699, folio, are both incomplete, the latter including only the first two letters of the alphabet; but, even if they had been finished works, they could have afforded little or no help in ascertaining the actual contents of the collection. A good analytical account of this library is still a desideratum.

Library of Stuttgart.

The public library at Stuttgart contains 197,000 printed volumes, and 1800 volumes of manuscripts. It is divided into three departments, each of which is under the superintendence of one of the librarians, who are charged with the purchase and binding of books, the keeping of catalogues, and other duties. The general government of the library is vested in directors, who endeavour, as far as their means allow, to procure every thing that is of real worth or value. Recommendations from any of the authorities of the state, for the purchase of particular works, are invariably attended to. All booksellers in the kingdom are required to furnish a copy of every work published by them. To certain persons, and under certain regulations, books are allowed to be lent out from the library. The annual expense of the establishment amounts to about 7000 florins, of which about 4000 are expended in the purchase of books; and it is defrayed out of the public treasury. There is a provincial library at Tubingen.[1]

[4] *De Prisca Ægyptiorum Litteratura, Commentatio prima*, tab. ix. et seq.

Other German libraries.

The library of Wolfenbuttel is little inferior to that of Stuttgart; it contains 190,000 printed volumes, with a few manuscripts. Besides the libraries connected with various public institutions, as the Seckenburg Museum, and the institution of Staendel for the Fine Arts, there is a public library at Frankfort, called the *Stadt Bibliothek.* This collection contains 50,000 volumes of printed books, and 500 volumes of manuscripts, of which 20 are Abyssinian, 12 Turkish and Persian, 6 Hebrew, 2 Indian and Burmese, and the rest in Latin, German, and other languages. No catalogue of this library has been published since 1728; but a new descriptive one is, it seems, in progress. The annual expense, which amounts to about 4400 florins, is principally contributed by the public treasury.[2] The library of Naumburg was founded in the sixteenth century by Julius Pflug, bishop of that place, who is celebrated in ecclesiastical history as a zealous opponent of the Reformation, and as one of the three divines deputed by Charles V. to draw up the plan of the Interim in 1548. In the seventeenth century this library received a further augmentation by the purchase of the collection of books formed by Thomas Reinesius. The printed books and manuscripts, though few in number, are of considerable value. Amongst the latter are the Scholia of Olympiodorus on several of Plato's Dialogues, written in the sixteenth century; a fragment of Orpheus's Argonautics, of the fifteenth; the Olympic Odes of Pindar, of the sixteenth, apparently transcribed from an ancient manuscript; the Cassandra of Lycophron, with the Commentary of Tzetzes, dated 1438; and several tracts of Jamblichus, on the Pythagorean philosophy, belonging to the fifteenth century.[3] From these manuscripts Müller, in his excellent catalogue, printed at Leipzig (1806–1811, in 8vo) has given a selection of various readings.[4]

Dutch libraries.

There are many libraries in Holland, indeed almost every city has one, but the principal collection is that belonging to the university library of Leyden. This library was founded by William I. prince of Orange, and is justly celebrated throughout Europe for the many valuable specimens of Greek and oriental literature with which it abounds. To it Joseph Scaliger bequeathed his fine collection of Hebrew books; and it was further enriched by the learned Golius, on his return from the East, with many Arabic, Turkish, Persian, and Chaldaic manuscripts. In addition to these, it received the collections of Holmanus, and particularly those of Isaac Vossius and Ruhnken; the former containing a great number of valuable manuscripts, supposed to have once belonged to Christina queen of Sweden; and the latter, an almost entire series of classical authors, with a collection of manuscripts, perhaps unique, amongst which are to be found copies of several that were consumed by fire in the Abbey of St Germain-des-Prez. The library at Leyden is computed to contain 60,000 printed volumes, and 14,000 volumes of manuscripts, many of which, as we have seen, are equally curious and valuable.[5] Of the public library at Amsterdam, Peignot drily remarks that it would be more useful if the books it contains were arranged in better order and method.[6]

Belgian libraries.

At Brussels there are two principal libraries; one of which, composed of printed books, belongs to the city, and the other, consisting entirely of manuscripts, belongs to the government. The former was founded on that which formerly appertained to the house of Burgundy, a family that gave to Flanders several counts or earls, by whose liberality it was enriched with numerous valuable manuscripts which, it would appear, are now separated from the collection. Santander[7] traces the history of this library through its various fortunes, having been successively burned, buried under ground, and decimated by French commissaries on the capture of Brussels. Though restored to its ancient splendour by the care of Count de Cobentzel and of Prince Stahremberg, minister plenipotentiary of the empress-queen, its prosperity was of short duration. For, when the French armies overran the Netherlands, and occupied Brussels, in 1797, Laurent, the representative of the people, caused seven waggon-loads of books and manuscripts to be taken from the Burgundy Library; and some time afterwards, Wailly, Leblond, and others, deputed to commit a second spoliation, selected about 200 manuscripts for the National (Royal) Library at Paris. In 1797, a place was provided for the reception of the books belonging to the Burgundy Library; and in 1798, the collection was enriched with all that was most valuable from the great depôt of the Cordeliers, which was then broken up. Since that period the Brussels Library has, by gradual acquisitions, become more extensive than ever, and at present contains 140,000 volumes of printed books. The library of the government, as it is called, comprises 15,000 volumes of manuscripts, which, however, have not been particularly described. The city library is open four days in the week, from ten o'clock in the morning until two in the afternoon, and the public have free access to the collection. The ordinary annual expense of this establishment amounts to 4800 francs (a mere trifle), but additional sums are from time to time granted for the purchase of books. The library of the government is open every day from nine in the morning until four in the afternoon; and the annual expense amounts to 10,000 francs. The first of these establishments is supported by the city, the second by the government out of the public treasury. The provincial libraries of Belgium are those of Antwerp, Bruges, Ghent, Liège, Louvain, Mons, Namur, and Tournay, three of which (those of Ghent, Liège, and Louvain) are under the direction of the universities established at these places, whilst the others are under the superintendence of the local authorities.[8]

Libraries of Hungary.

It is well known that a noble library, rich in valuable manuscripts, had been formed at Buda, by the celebrated Matthias Corvinus, king of Hungary; but this collection was dispersed, on the capture of Buda by the Turks under Solyman in 1526; and Cardinal Bozman in vain offered the conqueror two thousand crowns to restore this part of the spoil. Some of the books which belonged to it have been found in the Imperial Library at Vienna, in that of Wolfenbuttel, and in the private collection of Morelli, librarian of St Mark's at Venice.[9] By the liberality of Count Sczecheny, his private collection at Pesth has become the library of the kingdom of Hungary. The books are entered alphabetically in the catalogue and supplements, and classed in the indexes according to the subjects. M. de Miller, librarian to the count, having discovered several works printed at Gros-waradin in the sixteenth and seventeenth centuries, published an account of them at Pesth in 1804.[1]

Li ries of land.

Of Poland it may be said, in a bibliographical as well as political sense, *Stat magni nominis umbra.* The literary treasures of that ancient kingdom have gone to enrich its principal spoiler; and it is at Petersburg rather than at Warsaw that we must seek for evidence of what it originally possessed. What is called the King's Library at Warsaw does not much exceed 20,000 volumes, most of which are modern; but it contains a manuscript, in three folio volumes, with nearly two hundred fine drawings, descriptive of the antiquities excavated at Velleia between the years 1760 and 1765. The university of Warsaw, founded by the Emperor Alexander in 1816, had accumulated a library of about 150,000 volumes; but, since the events of 1830 and 1831, every book and pamphlet in it, conceived to be hostile to the Russian government, have been removed, and numbers of scientific works have likewise been abstracted and sent off to St Petersburg. The university of Cracow has also attached to it a library, containing about 4000 manuscripts, amongst which is a Latin encyclopædia, in a large folio volume, written by Paul of Prague in 1459. But the most extensive and valuable collection in Poland was that which Count Zaluski and his brother had formed, and which, in 1747, was devoted to the public. The Zaluski Library, called also the Library of the Republic, originally consisted of 300,000 volumes, including upwards of 50,000 duplicates, which were subsequently disposed of; and by the sale of these, together with the losses sustained by various depredations, the collection was supposed, in 1791, not greatly to exceed 200,000 volumes. At length, in 1795, this library was unceremoniously seized by Suwarof, hastily packed up, and despatched to St Petersburg, to aggrandise the conqueror with the literary spoils of Poland.

Th mpe- rial brary at S Pe- ters rg.

The Imperial Library of St Petersburg is, according to Mr Edwards, "the *creation* of but a few years."[2] We confess our inability to understand what this gentleman means by the word "creation" here employed by him. A robber does not surely create the wealth which he forcibly appropriates. Considerably more than half the actual contents of the Imperial Library were obtained by one act of wholesale spoliation. The French, when they conquered Italy and Belgium, decimated the libraries of those countries. But the Russians, when they triumphed over the independence of Poland, carried off entirely the largest collection of books which that country could boast of. The original founder of this library was Joseph, count de Zaluski, bishop of Kiof. In the space of forty-three years he had acquired, at his own expense, above 200,000 volumes. His brother, Andrew Zaluski, bishop of Cracow, enriched this numerous collection, as well with books drawn from the museum of John III. king of Poland, as with those which he collected from the libraries of his uncles, Andrew Olszofski, primate of the kingdom of Poland, Prince Andrew Chrysostom, bishop of Warmia, and Louis Bartholomew, bishop of Plock; and after having joined to these the collection in his own cabinet, he transferred the whole, in 1742, to a house which had previously belonged to the family of Danilovitch, and had probably come to him by inheritance. In 1747 he rendered it public, and fixed an annual income or endowment for its support and increase. After the death of this prelate, his brother, Joseph Zaluski, still further augmented it by the addition of a great number of volumes, and, by his will, made in 1761, bequeathed it, along with the house in which it was deposited, to the college of Jesuits at Warsaw.[3] After the suppression of that order in 1773, it was placed under the care of the commission of education, and at last transferred to St Petersburg in 1795, as already mentioned. This transportation being made by land, and along roads which the late season of the year rendered impracticable, several cases suffered much from the inclemency of the weather, others were broken or damaged, and the books which they contained spoiled, misplaced, or separated, and the sets broken. The collection was conveyed to the imperial cabinet in two convoys, and after the inventory had been completed on the 23d of February 1796, it was found that the collection still amounted to 262,640 volumes, and 24,573 prints. This library, thus seized and carried off, and which had been packed in such haste at Warsaw, that the books had been huddled in without any order, so that the volumes of the same work were found dispersed in different cases, comprised in general all that relates to the sciences, the arts, and the belles-lettres. The theological, and, after it, the historical and literary branches, were the most considerable. The theological department alone comprehended above 80,000 volumes. It was also rich in topography, especially the histories of towns; and the literary branch included a precious collection of classical books and works on bibliography; but the departments of philosophy, mathematics, physics, voyages, and antiquities were very incomplete.[4] Such was the "creation" which formed the basis of the Imperial Library at St Petersburg, and but for which that collection, instead of now ranking in the first class, would scarcely have been entitled to a place in the third.

This library, augmented by various other collections, amounts to about 400,000 printed volumes, and 16,000 volumes of manuscripts. Its management is detailed at length in the Appendix to the Report of the Select Committee on the British Museum (p. 449, et seq.), to which we refer. The total annual expense for the support of the Imperial Library, and paying the salaries of the employés, amounts to 45,000 roubles; and the paltry sum of 7000 roubles is the utmost that is allowed in any year for the purchase of books; from which we may infer that its principal chance of further increase depends, not on the liberality of the Russian government, but on the probability of some new conquest, followed closely by a fresh act of spoliation. The public is admitted to the library every Tuesday from eleven o'clock in the forenoon to three in the afternoon, to visit the establishment, and on the Wednesdays, Thursdays, and Fridays of each week, to read or make extracts therein.

A most laudable attempt is making to introduce a new bibliographical system of classification, which we shall en-

---

[2] Letter to Benjamin Hawes, Esq. M. P. p. 35, note.

[3] "The celebrated library of Zaluski at Warsaw," says Denis, in his *Introduction to the Knowledge of Books*, "was opened to the public in 1747. It must contain at present near 300,000 volumes. Benedict XIV. in 1752, issued a bull of excommunication against those who should dare to commit depredations on this library; but, notwithstanding, many books were carried off, particularly during the late troubles. In 1747, the laborious librarian, Ianozki, made notices of the rare books printed in Polish; and, in 1752, he published a catalogue of the manuscripts in this library. After the death of its founder, the Bishop of Kiev, the king and the commonwealth took possession of this treasure, in spite of the attempts made by the heirs to retain it." (Denis, *Einleitung in die Bücherkunde*, Wien, 1777, th. i. p. 184.)

Modern Libraries.

deavour to describe as briefly as possible, by exhibiting the plan of the catalogues as stated in the official returns.[1] These are, 1st, *Le catalogue alphabétique des livres, par ordre des matières*; 2d, *Le catalogue alphabétique des auteurs*; and, 3d, *Le catalogue raisonné, où les matières seront classées d'après le nouvel ordre bibliographique, avec des observations sur les livres et sur les éditions rares.* Their redaction must be exemplified rather than described. The books already entered in the catalogues of the different sections of the library have their titles re-transcribed on separate *feuillets*, or slips of paper, after the following model:

Danicorum Monumentorum Libri Sex:
e spissis antiquitatum tenebris et in Dania ac Norvegia extantibus ruderibus eruti ab *Oloa Worm.* D. Medicinæ in Acad. Haffn. professore publ.
Haffniæ, apud Joachimum Moltkenium, Bibliopolam ibidem primar. A° MDCXLIII.

The *feuillets*, or slips, thus prepared, are daily distributed amongst the employés, each intrusted with a particular division, and taking the titles belonging thereto, which are arranged in portfolios, for the purpose of facilitating their assortment. If a book treat of several subjects, it is first entered under that to which it most immediately belongs, and afterwards under the others. Each employé then inscribes on these *feuillets*, severally, the initial letter of the title, the author's name, the class, division, section, and position in the library, of the book, its size and number, as in the following model:

D		O. Worm.
Historia. Paralipomena Historica Archæologia.	Danicorum Monumentorum libri sex: e spissis antiquitatum tenebris et in Dania ac Norvegia extantibus ruderibus eruti ab *Oloa Worm.* D. Medicinæ in acad. Haffn. Professore publ. Hafniæ, Apud Joachimum Moltkenium, Bibliopolam ibidem primar. Anno MDCXLIII (1643).	VII. B. 1 vol. in fol. N. 3673.

The slip, thus prepared, is transferred to the employés engaged on the several catalogues; 1st, to the alphabetical catalogue, in the order of subjects; 2d, to the alphabetical catalogue, in the order of authors' names; and, 3d, to the *catalogue raisonné*, or classed catalogue; so that all of these proceed simultaneously without the least difficulty or confusion. With regard to the first, in the alphabetical order of subjects, it is held sufficient to inscribe in the catalogue the titles of books in an abridged form, which it is unnecessary to exemplify. It appears by the official returns, that the number of books put in order is about 103,000, and that the number already entered in the catalogues amounts to about 90,000.[2]

Academy of Sciences.

The Academy of Sciences at St Petersburg was instituted by Peter the Great, who, in his travels, had observed the benefits resulting from public societies for promoting the advancement of knowledge. The library of the Academy originated in 2500 volumes which the Czar had, *more Rossico*, seized at Mittau in his Swedish campaign, and which Catharine I. presented to the newly-instituted society. It continued to increase, by the bounty of succeeding Czars, and, in 1802, received an important addition in the library and cabinet of Count Boutourlin, purchased by the Emperor Alexander. This collection is now open to the public two days in the week, and contains about 70,000 volumes. Some interesting particulars relating to this library may be found in the works of different authors.[3]

Libraries at Copenhagen.

There are three public libraries at Copenhagen, viz. the King's Library, the University Library, and Classen's Library. The King's Library contains 400,000 volumes of printed books, and 20,000 volumes of manuscripts. The University Library contains about 110,000 printed volumes, all collected since the year 1728, when the original library was destroyed by fire; together with 1761 Icelandic, 202 oriental, and 1228 other manuscripts, partly classical, partly connected with Danish history, besides manuscript collections of the classics. Classen's Library contains about 35,000 printed volumes, but possesses no manuscripts. These libraries, consisting of 568,000 volumes printed and manuscript, are accessible to all respectable householders, and likewise to strangers introduced by such; and, besides, the books are, under certain restrictions, allowed to circulate. The King's Library is general, and about equally complete in all the branches of human knowledge. The University Library is also to a certain extent general, but the main body of the collection has been made chiefly with reference to academical education. Classen's Library consists principally of books of geography, travels, natural history, and agriculture. The administration of these libraries seems to be equally economical and efficient, and is conducted solely with a view to public utility, which, in this case, means public instruction.[4]

Swedish libraries.

The public libraries, in Sweden are the Royal Library, situated in the northern wing of the king's palace at Stockholm, and the library called Benzielstjerna-Engeström, founded by private individuals, but to which admission is readily granted on recommendation. The Royal Library, which was founded by Gustavus Vasa, and enlarged by the liberality of succeeding sovereigns, contains 70,000 volumes of printed books, with 2500 volumes of manuscripts, besides 16,500 diplomas, and is open to the public every day excepting Saturdays, Sundays, and holidays; besides, books are lent out on respectable recommendation. The library of Benzielstjerna-Engeström contains about 12,000 volumes of printed books, and 3000 volumes of manuscripts, rich in materials for Swedish biography. Besides these, there are libraries attached to the different academies. The number of provincial libraries in Sweden, including those of the universities of Upsala and Lund, is thirteen. That of Upsala, which was founded by Gustavus Adolphus, is the largest in Sweden, and contains 100,000 printed volumes, with 600 volumes of manuscripts. A catalogue of the collection, by Professor Aurivilius, was printed in the year 1814, in two vols. 4to.[5] The library of Lund was founded at the same time as that university, by Charles X., and possesses about 40,000 volumes. These libraries are supported and increased by an annual grant from the state, and by a fee paid by each student on entering the universities. They are open every day, and each student can borrow books, on the responsibility of a professor, or of some other respectable person. In those provincial towns where large public schools, called *gymnases*, are established, there are also public libraries, to the number of about eleven in all. These libraries, which have been founded by private individuals, are kept up much in the same way as those belonging to the universities.[1]

[4] Appendix to Report, p. 483.

[5] One of the apartments of this library contains a deposit, the supposed contents of which have excited much conjecture and speculation amongst the learned. The deposit alluded to consists of a large box, upon which stands another of smaller dimensions, both of which are secured by means of strong chains and locks. These were presented to the university by Gustavus III. with strict injunctions that they should not be opened for *fifty* years. When that period expires, which will be in the year 1842, they will probably be found to contain a history of his own time, with various documents, letters, &c.

Li ries of t Uni- ted ates of neri- ca.

In the United States of North America there are forty-three incorporated colleges or universities, of which thirty have libraries of greater or less extent, containing altogether 128,118 volumes. The largest college library is that of Harvard, which contains 30,000 volumes; and the next is that of St Mary's College, Baltimore, which possesses 10,000 volumes. Besides these, there are four colleges which have libraries to the amount of about 8000 volumes each. A catalogue of the library at Harvard College, Massachusetts, was printed in 1830, in three volumes 8vo; from which it appears that the number of books, which, in 1790, amounted to only 12,000 volumes, now exceeds 30,000, besides several thousands of tracts. The first and second volumes of this catalogue contain a list of the books in alphabetical order; and the third consists of a systematic or classed index to the alphabetical catalogue. There are several other considerable libraries in the United States, as the Public Library at Philadelphia, the Congress Library at Washington, and a few others of less note. The Loganian Library, which, in 1791, was incorporated with the Philadelphia Public Library, contained about 15,000 volumes, amongst which were many rare works in classical literature.[2]

Li ries of t East.

Oriental libraries are, in general, but limited collections, the contents of which possess little interest or value to Europeans. Their general character, however, will be most satisfactorily indicated by the description of some of them.

Tu ish lib ries.

At Constantinople there are, within the walls of the seraglio, two libraries, which were founded by Achmed III. and Mustapha III., and enriched with books acquired by themselves or their successors. These libraries contain upwards of 20,000 volumes, and are gradually increased, either by purchase, by donations made to the sultan by his grandees, or by confiscations of the effects of public officers, amongst which books are commonly to be found.[3] Much uncertainty has prevailed, and many erroneous reports have been circulated, respecting the contents of these libraries. The Abbé Sevin, who arrived at Constantinople in December 1728, failed to obtain admission into the sultan's library; and, deterred by the assurances he had received, that Amurath IV. had caused all the Greek manuscripts to be burned, he deemed any further research or inquiry to be hopeless; whilst succeeding travellers, relying on statements of a different kind, have confidently asserted that in these libraries were preserved the ancient collections of the Greek emperors.[4] More fortunate than his predecessors, however, Toderini, after three years' unremitting attempts during his residence at Constantinople, found means to procure transcripts of the catalogues of the libraries in the seraglio, through the instrumentality of a page who clandestinely copied a few lines every day.[5] From the inquiries of the learned Abbate, it appears that the merits of this double collection had been greatly exaggerated. The libraries of the seraglio are much inferior to some of those which are open to the public. Commentaries, explanations, marginal notes, and other writings on the Koran, form the subjects of the largest portion; to which succeed treatises on jurisprudence (also accompanied with notes and commentaries), on philosophy, logic, astronomy, arithmetic, medicine, and ethics. The historical works are few in number, and chiefly confined to the Ottoman empire. There are some manuscripts in the Greek, Latin, and other European languages; but no traces whatever have been discovered of the lost decades of Livy, of the writings of Homer or Tacitus, or of those parts which are wanting to complete the works of other ancient authors.[6]

Besides those of the seraglio, Constantinople possesses thirty-two public libraries, all varying in extent, but more or less celebrated for the number and value of their manuscripts, which are neatly bound in red, green, or black morocco. The Mahommedans have a peculiar method of indorsing, placing, and preserving their books. Each volume, besides being bound in morocco, is preserved from dust in a case of the same material; and on it, as well as on the edges of the leaves, the title is written in large and legible characters. The books are placed one upon another in presses ornamented with trellis-work, and are disposed along the wall, or in the four corners of the library. All these collections are open to the public throughout the year, excepting on Tuesdays and Fridays; the librarians are as polite and attentive as Turks can be, to those whom curiosity or love of study attract thither; and every one is at liberty, not merely to peruse, but to make extracts from, the books, and even to transcribe them entirely, provided this be done within the walls of the library. To facilitate literary researches, each library is furnished with a catalogue, containing the title, and giving a short account of the subject of each volume. Theology, including the Koran and commentators thereon, jurisprudence, medicine, ethics, and history, are the sciences chiefly cultivated by the Osmanlees. The books are all written with the greatest care, on the finest vellum; the text of each page is enclosed in a highly ornamented and gilt frame-work; the beginning of each chapter or section is splendidly illuminated; and the prices of the manuscripts vary in proportion to the beauty of the characters.[7] Under the reign of the present sultan, Mahmoud, the introduction of European discipline, and, to a certain extent, of European customs and manners, is fast paving the way for a still more important innovation; the introduction of European knowledge and civilization, with the subversion of those fanatical prejudices which, nurtured by ignorance and inflamed by religion, present the most formidable obstacle to the improvement of nations.[1]

Library of Mount Sinai.

The library of the convent of Mount Sinai was found by Mr Burckhardt to contain a great number of Arabic manuscripts, and some Greek books; but the former proved to be of little literary value; and of the latter, Burckhardt carried away two beautiful Aldine editions, a Homer, and an Anthology. The priests refused to show him their Arabic memorandum-books previous to the fifteenth century; but from those which he was permitted to inspect, he copied some very interesting documents concerning the former state of the country.[2]

Indian libraries.

Of the libraries in India, whether composed of European or of native works, the want of the requisite information prevents us from attempting to give any details. The following account of the largest library at Goa, that of the Augustinian monks, extracted from the journal of a tour made by Sir James Mackintosh, is almost the only notice of the kind that we have met with, and it is certainly by no means flattering. "The books," says he, "are about 10,000, chiefly Latin and Portuguese, with a few Spanish, a very few Italian and Greek, no French, and of course no English, and none of any other language. There are not above twenty printed since the close of the seventeenth century. There are a few bad editions of classics, but not a complete edition even of Cicero himself; a great many schoolmen, casuists, and canonists, with some jurists; very little history, scarcely any of modern times, except a little Portuguese; about ten volumes of Portuguese and Spanish poetry; no morals, but as the handmaid or rather slave of superstition; no politics, no political economy, no astronomy, no chemistry, no zoology, no botany, no mineralogy, and no book even on mathematics by Euclid. I did not know before that the world had produced 10,000 such useless and pernicious books, or that it had been possible to have formed a large library, with so curious an exclusion of whatever is instructive or elegant."[3] At the different presidencies, and in some other parts of British India, are collections, more or less extensive and valuable, of European and native productions; but they have not been particularly described. Of the native libraries of India, we know but little. That of Tippoo Sahib, which fell into the hands of the British when his capital was taken, consisted, according to Stewart's catalogue, of nearly 2000 volumes, many of them highly ornamented. In China and Japan, and likewise in the capital of the Burman empire, there are considerable collections, though of the precise nature of their contents we still remain entirely ignorant.

Having thus completed our laborious survey, which we have endeavoured to render as complete as the materials to which we have had access would admit, it now only remains to refer the reader to the article Bibliography, as containing various inquiries intimately connected with the present subject; and which may, in fact, be said to constitute the Science of those who are intrusted with the formation and superintendence of Libraries. (A.)

LIBRATION, in *Astronomy*, an apparent irregularity of the moon's motion, by which she seems to librate about her axis, sometimes from the east to the west, and at other times from the west to the east. See Astronomy, *Index*.

LIBURNIA, in *Ancient Geography*, a district of Illyricum, extending towards the Adriatic, between Istria on the west, Dalmatia on the east, and Mount Albius on the north. The people were called *Liburni*. The apparitors, who at the command of the magistrate summoned the people from the country, were called *Liburni*, because generally men of *Liburnia*.

LIBURNUS, in *Ancient Geography*, a mountain of Campania. It was also a port of Tuscany, and is now *Livorno*, or *Leghorn*. Long. 11. E. Lat. 43. 30. N.

LIBYA, in general, a term which, according to the Greeks, denoted Africa. It was derived from *Lub*, thirst, being a dry and thirsty country. See Africa.

Libya, in a more limited sense, was the middle part of Africa, extending north and west, between the Mediterranean to the north, and Ethiopia to the east. It was divided into the Hither or Exterior Libya, and the Farther or Interior. The former lay between the Mediterranean on the north, and the Farther Libya and Ethiopia beyond Egypt on the south. The Farther or Interior Libya was a vast country, situated between the Hither Libya on the north, the Atlantic Ocean on the west, the Ethiopic on the south, and Æthiopia beyond Egypt on the east.

Libya, in a still more confined sense, called *Libya Propria*, was a northern district of Africa, and part of the Hither Libya, situated between Egypt on the east, the Mediterranean on the north, the *Syrtis Major* and the *Regio Tripolitana* to the west, the Garamantes and Æthiopia beyond Egypt to the south. This Libya was again subdivided into Libya taken in the strictest sense of all, and into *Marmarica* and *Cyrenaica*. Libya in the strictest sense was the most eastern portion of *Libya Propria*, next to Egypt, with Marmarica on the west, the Mediterranean on the north, and the Nubi, now called Nubia, to the south.

LICENSE, in *Law*, an authority given to a person to do some lawful act.

LICENSER of Books, an officer without whose permission, formally granted, no book could be published. It has been proved by Beckman that such an office was established, not only in the Roman empire, but also in the states of Greece. All the copies of the works of Protagoras which could be procured were burned at Athens by the public crier, and the satirical works of Labienus shared the same fate under the reign of the Emperor Augustus. Not long after the invention of printing, laws were enacted for subjecting books to examination. See Bibliography.

LICENTIATE, one who has obtained the degree of a license. The greater number of the officers of justice in Spain are distinguished by no other title than that of licentiate. In order to pass as licentiate in common law, civil law, and physic, they must have studied seven years, and in divinity ten. Amongst us a licentiate usually means a physician who has a license to practise, granted by the College of Physicians.

LICETUS, a celebrated physician of Italy, was born at Rappollo, in the state of Genoa, in the year 1577. He came into the world in the seventh month; but his father, an ingenious physician, wrapped him up in cotton, and nurtured him so carefully that he lived to be seventy-seven years of age. He was trained with great care, became a distinguished man in his profession, and was the author of a great number of works, particularly one *De Monstris*. He was professor of philosophy and physic at Padua, where he died in the year 1655.

---

[1] The publication of the Ottoman States Gazette, under the title of *Takwimi Wokai*, or Tables of Events, has proceeded with great spirit since its first appearance in January 1832, and contains a variety of articles which throw considerable light on the nature of the reforms which are in progress throughout every department of the state. In this respect, the *Takwimi Wokai* is a far more interesting paper than the *Moniteur Ottoman*, which is by no means the French original of the former, as the public may perhaps have been led to conclude.

[2] *Travels in Nubia*, p. lxviii.

[3] *Life of the Right Hon. Sir James Mackintosh*, vol. ii. p. 85, London, 1836, 8vo, 2d edition.

LICHTENBERG, a part of the duchy of Saxe-Coburg, but detached from the other territory of that state. It is situated to the west of the Rhine, surrounded by the lands of Prussia, Bavaria, and Hesse-Homberg. It extends over 248 square miles, contains two towns, ninety-six villages, 4038 houses, and 26,315 inhabitants. The capital is St Wendel, situated on the river Blies.

LICHTENSTEIN, a sovereign principality, one of the smallest in Germany. It is situated on the frontier of Switzerland and the Tyrol, and borders on the Rhine. It is fifty-five square miles in extent, and contains 1207 houses, in two towns and nine villages, with 5800 inhabitants. The revenue is said to be about L.2000 annually; but the prince has other territory, which has been mediatized, the income of which far exceeds that of the independent sovereign state.

LICHTERVELDE, a town of the Netherlands, in the province of West Flanders, and arrondissement of Bruges. It contains 4250 inhabitants, who are employed in linen manufactures.

LICINIUS Stolo, a Roman tribune, styled *Stolo* on account of a law he made, whilst tribune, that no Roman citizen should possess more than 500 acres of land; alleging, that when they occupied more, they could not cultivate it with care, nor pull up the useless shoots (*stolones*) which grow from the roots of trees. He is remembered also for having enacted, that one of the consuls should always be of a plebeian family. He lived about 362 B. C.

LICNON, in the Dionysiac solemnities, the mystical van of Bacchus, a thing so essential to all the solemnities of this god, that they could not be duly celebrated without it.

LICNOPHORI, in the Dionysiac solemnities, those who carried the licnon.

LICODIA, a city of the island of Sicily, in the kingdom of Naples, and province of Noto. It stands on a steep rock, rising above the river Dirillo, known as the Eubœa of Strabo. It is in a healthy situation, and contains 6950 inhabitants.

LICOLA, or **Lago di Licola**, a lake in the kingdom of Naples, anciently famous for excellent fish; but, in the year 1538, an explosion of a volcano changed one part of it into a mountain of ashes, and the other into a morass. It was anciently known by the name of the Lucrine Lake, the oysters of which are highly commended by Horace.

LICTORS, amongst the Romans, were officers established by Romulus, who always attended the chief magistrates when they appeared in public. The duty of their office consisted of three parts: 1. *Submotio*, or clearing the way for the magistrate they attended. This they did by word of mouth; or, if there was occasion, by using the rods they always carried along with them. 2. *Animadversio*, or causing the people to pay the usual respect to the magistrate, as to alight, if on horseback or in a chariot; to rise up, uncover, make way, and the like. 3. *Præitio*, or walking before the magistrates. This they did not confusedly, or altogether, nor by two or three abreast, but singly, following one another in a straight line. They also preceded the triumphal car in public triumphs; and it was a further part of their office to arrest criminals, and to act as public executioners. Their ensigns were the *fasces* and *securis*. As to the number of lictors allowed each magistrate, a dictator had twenty-four, a master of the horse six, a consul twelve, a prætor six; and each vestal virgin, when she appeared abroad, had one.

LIDDEL, Duncan, professor of mathematics and of medicine in the university of Helmstadt, was born in the year 1561, at Aberdeen, where he received the elementary part of his education in languages and philosophy. About the age of eighteen he repaired to the University of Frankfort, where he spent three years in a diligent application to the mathematics and to philosophy. From Frankfort he proceeded to Wratislau or Breslau in Silesia, where he is said to have made uncommon progress in his favourite study of mathematics, under the direction of a very eminent professor, Paulus Wittichius. Having studied at Breslau for the space of one year, he returned to Frankfort, and remained there for three years, giving the most intense application to the study of physic. A contagious distemper having broken out at that place, the students were dispersed, and Liddel retired to the university of Rostock. Here he renewed his studies, rather as a companion than as a pupil of the celebrated Brucæus, who, though an excellent mathematician, did not scruple to confess that he was instructed by Liddel in the more perfect knowledge of the Copernican system, and other astronomical questions. In 1590 he returned once more to Frankfort; but having there heard of the increasing reputation of the Academia Julia, established at Helmstadt by Henry duke of Brunswick, Mr Liddel removed thither; and soon after his arrival was appointed to the first or lower professorship of mathematics. From this, however, he was promoted to the second and more dignified mathematical chair, which he occupied for nine years, with much credit to himself and to the Julian Academy. In 1596, he obtained his degree in physic, was admitted a member of the faculty, and began publicly to teach physic. By his teaching and his writings he was the chief support of the medical school at Helmstadt, was employed as first physician at the Court of Brunswick, and had much practice among the principal inhabitants of that country. Having been several times elected dean of the faculties both of philosophy and physic, he had in the year 1600 the honour of being chosen protector of the university. But neither academical honours, nor the profits of an extensive practice abroad, could make Dr Liddel forget his native country. In the year 1604 he took a final leave of the Academia Julia; and after travelling for some time through Germany and Italy, he at length settled in Scotland, where he died in the year 1613, in the fifty-second year of his age. By his last will he bestowed certain lands purchased by him near Aberdeen upon the university there, for the education and support of six poor scholars. Amongst a variety of regulations and injunctions for the management of this charity, he appointed the magistrates of Aberdeen his trustees, and solemnly denounced the curse of God against any person who should abuse or misapply it. His works are, 1. *Disputationes Medicinales*, Helmstadt, 1603, 4to; 2. *Ars Medica succincte et perspicue explicata*, Hamburg, 1607, 8vo, dedicated to James VI. and divided into five books, viz. *Introductio in totam Medicinam, de Physiologia, de Pathologia, de Signorum Doctrina, de Therapeutica;* 3. *De Febribus Libri tres*, Hamburg, 1610, 12mo; 4. *Tractatus de Dente Aureo*, Hamburg, 1628, 12mo. This last production Dr Liddel published, in order to refute a ridiculous story then current, of a poor boy in Silesia, who, at seven years of age, having lost some of his teeth, produced a new tooth of pure gold. The imposture was discovered to be a thin plate of gold, skilfully drawn over the natural tooth by an artist of that country, with a view to excite the public admiration and charity. He was also the author of *Artis Conservandi Sanitatem Libri duo*, Aberdeen, 1651, 12mo; a posthumous work.

LIE, in morals, denotes a criminal breach of veracity. Archdeacon Paley, in treating of this subject, observes, that there are falsehoods which are not lies, that is, which are not criminal; and that there are lies which are not literally and directly false.

Cases of the first class are those, 1. where no one is deceived; as, for instance, in parables, fables, novels, jests, tales to create mirth, or ludicrous embellishments of a story, in which the declared design of the speaker is not to inform, but to divert; compliments in the subscription of a letter; a prisoner's pleading not guilty; an advocate asserting the justice, or his belief of the justice, of his client's cause. In such instance no confidence is destroyed, because none was reposed; no promise to speak the truth is violated, because none was given or understood to be given. 2. Where the person you speak to has no right to know the truth, or, more properly, where little or no inconvenience results from the want of confidence in such cases; as where you tell a falsehood to a madman for his own advantage; to a robber, to conceal your property; to an assassin, to defeat or to divert him from his purpose. It is upon this principle that, by the laws of war, it is allowable to deceive an enemy by feints, false colours, spies, false intelligence, and the like; but by no means in treaties, truces, signals of capitulation or surrender. The difference is, that the former suppose hostilities to continue, whilst the latter are calculated to terminate or suspend them.

As there may be falsehoods which are not lies, so there may be lies without literal or direct falsehood. An opening is always left for this species of prevarication, when the literal and grammatical signification of a sentence is different from the popular and customary meaning. It is the wilful deceit that makes the lie; and we wilfully deceive when our expressions are not true in the sense in which we believe the hearer apprehends them. Besides, it is absurd to contend for any sense of words, in opposition to usage; for all senses of all words are founded upon usage, and upon nothing else. A man may also act a lie; as by pointing his finger in a wrong direction, when a traveller inquires of him his road; or when a tradesman shuts up his windows, to induce his creditors to believe that he is abroad; for to all moral purposes, and therefore as to veracity, speech and action are the same, speech being only a mode of action.

LIEFKENSHOEK, a strong fortress of the Netherlands, in the province of East Flanders. It stands on the left bank of the Scheldt, opposite Lillo, and with it forms the chief defence of that river. It has four bastions, two ravelins, a ditch, and counterscarp, with only one gate towards the water; and the whole country on the land side can be laid under water when the defence requires it.

LIEGE (*Ligius*) properly signifies a vassal, who holds a kind of fee, that binds him in a closer obligation to his lord than other people. The term seems to be derived from the French *lier*, to bind, on account of a ceremony used in rendering faith or homage; which was by locking the vassal's thumb or his hand in that of the lord, to show that he was fast bound by his oath of fidelity. Cujas, Vigenère, and Bignon, choose rather to derive the word from the same source with *leudis* or *leodi*, loyal, faithful. But Du Cange coincides in the opinion of those who derive it from *liti*, a kind of vassals, so firmly attached to their lord, on account of lands or fees held of him, that they were obliged to do him all manner of service, as if they were his domestics. He adds, this was formerly called *litgium servitium*, and the person *litge*. In this sense, the word is used (Leg. Edw. cap. 29): *Judæi sub tutela regis ligea debent esse;* that is, wholly under his protection. By liege homage, the vassal was obliged to serve his lord towards all, and against all, excepting his father. In this sense, the word was used in opposition to simple homage, which only obliged the vassal to pay the rights and accustomed dues to his lord, and not to bear arms against the emperor, prince, or other superior lord; so that a liege man was a person wholly devoted to his lord, and entirely under his command. But it must be observed, there were formerly two kinds of liege homage; the one, by which the vassal was obliged to serve his lord against all, without exception even of his sovereign; and the other, by which he was bound to serve him against all, except such other lords as he had formerly owed liege homage to.

In our old statutes, lieges and liege people are terms peculiarly appropriated to the king's subjects; as being *liges, ligi,* or *ligati,* obliged to pay allegiance to him (8 Henry VI., 14 Hen. VIII. &c.), though private persons had their lieges too. *Reinaldus, Dei gratia, abbas Ramesiæ, præposito et hominibus de Brancestre, et omnibus vicinis Francis et Anglis salutem. Sciatis me dedisse terram Ulfe, in depedene (hodie depedale) huic Boselino, et uxori ejus Alfniæ; ea conditione quod effecti sint homines legis.*

Liege, a province of the Netherlands, formed in part out of what, before the French Revolution, was the independent ecclesiastical state of that name, and was by France divided into the departments of the Ourthe and of the Sambre and Meuse. It contains also small parts taken from the duchy of Limburg, from the county of Dahlen and the abbey of Stablo, and also of certain villages known by the name of *Terres de Redemption.* It extends in N. lat. from 49° 40′ to 50° 46′, and in E. long. from 4° 49′ to 5° 57′, and is 2255 square miles in extent. It comprehends four arrondissements, divided into nine cantons, and those into 466 communes, containing 360,000 inhabitants, who are chiefly of the Walloon race, and speak that language, though of late years the use of the French tongue has been very much extended. The face of the country in the northern part is hilly; but in the southern, the largest division is mountainous, where the Ardennes forms a considerable portion. The soil is very various. On both sides the Meuse, towards the province of Limburg, there are some plains of moderate fertility, and well cultivated; but on that part where the Ourthe joins the Meuse, and especially towards Luxemburg, the land is rocky and stony, with much slate, which last is the prevailing stone in the woody district of the Ardennes. Agriculture in the north affords moderate products, in the south very poor returns; so that an importation of corn is regularly required, though the extension of potatoes, which has taken place of late years, has diminished the demand for grain. The woods are one of the chief sources of the wealth procured from the soil, and they cover more than 200,000 acres. There are mines producing iron and coal, which, before the revolution effected in Brussels in 1830, was a great source of benefit, the former yielding employment to numerous persons in making ironmongery goods; and the latter being of vast importance when the fuel consumed in Holland was drawn by the Meuse from Liège, instead of being furnished by sea from England. Besides the iron manufactures, there are others of paper, woodwork, leather, beer, and corn spirits. The city of Liège, the capital of the province and of the arrondissement of the same name, is situated on the left bank of the Meuse, where it is joined by the Ourthe. It is in a picturesque and fertile district, in a valley of contracted extent. It is fortified, and defended by two powerful citadels on the western and northern sides. It is not well built, though there are some spacious houses and splendid churches, with pleasing promenades. It contains 8000 houses, and 48,000 inhabitants, who are chiefly employed in the fabrication of great guns and small arms, cutlery, and other iron wares. There are breweries, distilleries, and tanneries, and other branches of industry; but all have suffered severely by political occurrences.

LIEGNITZ, one of the governments into which the Prussian province of Silesia is divided, comprising the north-western part of Upper Silesia, and a part of Upper Lausatia. It extends over 4158 square miles. It comprises thirty-five cities or walled towns, and 1383 smaller towns and villages, and 713,362 inhabitants, of whom the Protestants and Catholics are nearly equal in number. The chief products are corn, fruit, and culinary vegetables, with much excellent flax. Of late years there are large flocks of sheep, the fineness of the wool of which has been improved by crosses of the better breeds. The chief industry is spinning. The capital is the city of the same name, situated on the river Katsbach, where the Blackwater falls into that stream. It is surrounded with walls, but for a promenade rather than defence; and has four gates, with an old castle. It contains two Lutheran and four Catholic churches, several hospitals and courts of law, and a gymnasium, with 780 houses, and about 11,500 inhabitants. It is a place of active manufacturing industry, producing cotton goods of various kinds, camlets, serges, and other woollens, leather, Prussian blue, lace, starch, and musical instruments, and has several breweries and distilleries. This place is remarkable for a battle fought in 1760, in which the Austrians were defeated by the Prussians. Long. 16. 7. 1. E. Lat. 51. 12. 30. N.

LIER, or Lierre, a city of the Netherlands, in the province of Antwerp, and arrondissement of Mechlin. It stands at the junction of two small streams, which, when united, form the river Neethe. It contains 10,500 inhabitants, who are industriously occupied in distilleries, breweries, oil-mills, salt-works, and in printing calicoes. Long. 4. 26. E. Lat. 51. 9. N.

LIEVENS, John or Jan, a celebrated painter, was born at Leyden in 1607. He discovered an early inclination for the arts, and was the disciple, first of Joris van Schooten, and afterwards of Peter Lastman. He excelled principally in painting portraits, but he also executed several historical subjects with great success. He came over to England, where he resided three years, and painted the portraits of Charles I., the queen, the prince of Wales, and several of the nobility; after which he returned to Antwerp, where he met with full employment for his pencil. We have several etchings by this master, which are performed in a slight but masterly manner. The chiaro scuro is very skilfully managed in them, so as to produce a most powerful effect. His style of etching bears some resemblance to that of Rembrandt; but it is in general coarser, and less finished.

LIEOU-KIEOU, or Loo-Choo. See Loo-Choo.

LIEUTAUD, Joseph, counsellor of state and first physician at the court of France, was born at Aix, in Provence, and resided principally there till he took the degree of doctor of physic. After this he prosecuted his studies for some years at Montpellier, and having returned to Aix, he soon acquired extensive practice, and became eminent for literary abilities. He resided there till the year 1750, when he was invited to act as physician to the royal infirmary at Versailles. There he practised with such reputation and success, that he soon arrived at the head of his profession; and in the year 1774, upon the death of M. Senac, he was appointed chief physician. His extensive engagements in practice did not prevent him from cultivating the science of physic in all its branches, and from freely communicating to others the result of his own studies. He published many valuable works, amongst which the following may be accounted the most remarkable, viz. 1. Elementa Physiologiæ; 2 Précis de la Médecine; 3. Précis de la Matière Médicale; 4. Essais Anatomiques; 5. Synopsis universæ praxeos Medicinæ; 6. Historia Anatomico-Medica. He died at Versailles in 1780, aged seventy-eight.

LIEUTENANT, an officer who supplies the place and discharges the office of a superior in his absence. Of these, some are civil, as the lord-lieutenants of kingdoms, and the lord-lieutenants of counties; and others are military, as the lieutenant-general, lieutenant-colonel, &c.

Lord-Lieutenant of Ireland is properly a viceroy, and has all the state and grandeur of a king of England, except being served upon the knee. He has the power of bestowing all the offices under the government, of dubbing knights, and of pardoning all crimes, except high treason.

Lord-Lieutenants of Counties are officers who, upon any invasion or rebellion, have power to raise the militia, and to give commissions to colonels and other officers, and to arm and form them into regiments, troops, and companies. Under the lord-lieutenants, are deputy-lieutenants, who possess the same power; these are chosen by the lord-lieutenants, out of the principal gentlemen of each county, and presented to the king for his approbation.

Lieutenant, in the land service, is the second commissioned officer in every company both of foot and horse, next to the captain, and who takes the command upon the death or absence of the captain.

Lieutenant of a Ship of War, the officer next in rank and power to the captain, in whose absence he is accordingly charged with the command of the ship, as also the execution of whatever orders he may have received from the commander relating to the king's service. See Navy.

LIFE is peculiarly used to denote the animated state of living creatures, or the time during which the union of the soul and body lasts. See Physiology.

Life, Duration of. See Mortality.

LIFE-PRESERVERS.

Although it too frequently happens, that an accident, which materially endangers the life of an individual, deprives him, in the mean time, of that presence of mind which alone would enable him to take proper measures for his safety; yet to have meditated, in an interval of leisure, upon the best method of proceeding in case of emergency, must tend greatly to diminish the embarrassment and confusion that commonly accompany the accident, even if it should not be thought necessary to provide any particular apparatus for the purpose of escaping the danger. There are also many ways in which those who are not immediately involved in the disaster may contribute to the preservation of life, whether actuated by interest, or by humanity only; and the modes of relief will, therefore, be naturally divided into the *internal* and the *external*, whether relating to *fires* or to *shipwrecks*.

Sect. I.—*Internal Fire-Escapes.*

Whenever a family establishes itself in a residence not detached from others, it becomes of importance to ascertain what facilities the house affords for ascending to the roof, and for passing to those of the neighbouring houses. It is scarcely possible that a conflagration should extend at once to the contiguous houses on each side, before the inhabitants of the house in question have had time to escape. But in a detached house, if there are not two or more staircases remote from each other, and even in a house contiguous to others, when there is no facility of communicating by the roof, it becomes highly expedient to provide some *internal means* of escaping through the windows in case of fire, and to have *on every floor* a good strong rope, with a hook or a loop at the end, by which it may be fastened to a bed-post, so as to enable an active person to descend by its help out of the window, finding from time to time a partial footing in the inequalities of the wall. This process will be greatly facilitated by having the rope knotted at intervals of about a foot throughout its length; the knots being nearly as convenient as the blocks or clips that are sometimes made for the purpose of retarding the descent, by holding them, and regulating the friction by the pressure of the hand[1] (Plate CCCXXIII. fig. 13); unless the clip be attached to a strong cross bar, on which a person may sit, while he regulates the position of the clip by its handles, and allows himself to descend with more or less velocity at pleasure. The arrangement for this purpose may be made by a roller, or pipe, sliding on the rope, and pushed down so as to open the handles of the clip and tighten its teeth, when the person holds by the roller and draws it down (Plate CCCXXIII. fig. 12); and, on the contrary, the clip may be opened by pressing on the handles with the other hand, or with the thighs; or any other simple mode of regulating the clip may be adopted, provided that it be not liable to be misunderstood, or misapplied, in a moment of confusion. After all, a rope-ladder would perhaps be preferable, as not being liable to be deranged; it is often kept ready made in the shops; and, in the absence of any other rope, a common bed-cord will generally be found strong enough to support the weight even of a stout man; for a quarter-inch rope may be safely trusted with two hundredweight, and ought indeed to support three times as much if new and good.

Sect. II.—*External Means of Escape from Fire.*

The external means to be employed in cases of conflagration must be provided by the managers of fire-offices, or by other public officers; and every ingenious workman, whom they may employ, will be able, at his leisure, to devise such apparatus as he can the most conveniently execute, and to give it a full trial in the absence of all danger; it will, therefore, only be advisable that he should compare for himself the particular inventions which have been suggested for this purpose, and that he should choose from among them such as he thinks most likely to do him credit; and he may, indeed, very possibly find means of improving on any of them.

1. In Leupold's *Theatrum Machinarium* (plate liv. lv.) we find the representation of a chair calculated to be drawn up or down by means of pulleys. 2. Mr Varcourt obtained, in 1761, the approbation of the Parisian Academy of Sciences for his invention of a hollow mast, fixed in a waggon, and supporting a stage, with the means of ascending and descending. (*Hist.* p. 158.) 3. In the beginning of the present century, a fire-escape of Mr Audibert was approved by the Parisian Institute. (*Mém. Inst.* iv.) 4. A committee was also appointed for examining several similar inventions at the Lyceum of Arts, and a medal was awarded by it to Mr Daujon, for his apparatus, which consists of a platform carried on wheels, supported by three frames, with brass wires, on which boxes are made to slide up and down for the conveyance of persons or of furniture. (*Annales des Arts*, *Repertory* ii. vol. i. p. 439.) 5. Mr Collins's invention of pipes raised by ropes, and affording a centre to a long lever, is described in the fourth volume of the *American Transactions*, and in the *Repertory* (vol. xv. p. 35). 6. In the thirty-first volume of the *Transactions of the Society of Arts* (for 1813, p. 244), we have an account of a fire-escape invented by Mr Adam Young, for which he received a medal from the society. It appears to constitute by far the most portable of ladders, consisting of cross bars or rounds, connected by ropes, and having their ends fitted together, so as to form a pole, which is readily elevated to the window; and the rounds being separated, and the hooks at the end properly fixed to the window-frame, the whole forms itself into a very convenient ladder of a mixed structure. 7. The thirty-fourth volume, for 1816 (p. 227), contains a description of Mr Braby's fire-escape, consisting of a car made to slide on a strip of plank fixed to a pole, and governed by a rope, which is cased with iron, to protect it, in case of necessity, from the effect of the fire.

The modes of extinguishing fires are not precisely the objects of the present inquiry; but it deserves to be remarked, that the only rational principle on which the methods proposed have been founded, is that of cutting off the supply of air, either by a coat of water or steam, or by means of some chemical substance, capable of forming an impenetrable varnish, or glazing, on the surface of the combustible materials. A mixture of clay, with sulphate of iron and alum, has been proposed for this purpose; but its utility must obviously be extremely limited, and it must require to be applied with great address, so as to be brought into fusion exactly at the place where it is capable of protecting the substances not yet consumed.

Sect. III.—*Internal Means of Escape from Shipwreck.*

The means of escaping from shipwreck may be similarly divided into internal and external, or into the precautions to be taken by the ship's company, and the measures to be adopted by persons on shore. The internal means depend either on enabling the individuals to swim or float, or establishing a connection with the shore by ropes; and of the former, we may first consider those which require no particular preparation before the occurrence of the accident that calls them into action, and which are therefore the most universally applicable.

Of such expedients, the most effectual appear to be those which depend on the employment of empty water-casks for assisting the ship's company to drift on shore. 1. A paper on the arrangement of water-casks, to serve as floats in case of shipwreck, appears in the publications of the Society for the Improvement of Naval Architecture, dated in 1796 (vol. ii. 1, p. 51). 2. In 1818, Mr Grant of Bideford obtained a gold medal from the Society of Arts, for the invention of a life-preserver, consisting of a thirty-six gallon cask, with some iron ballast fixed on a wooden bed, and lashed to the cask, and with ropes round it for the men to hold; and it was found that ten men were supported by it with convenience in tolerably smooth water, the bung of the cask being well secured by cork (vol. xxxvi. p. 63.) The ballast could be of very little use, and a cask simply tied round with a rope, like a common parcel, would probably answer the purpose equally well. It would, indeed, be prudent for every ship in a storm on a lee shore, to have a few of her casks well emptied and stopped, and tied in this manner, before the actual occurrence of imminent danger. 3. In the thirty-seventh volume of the *Transactions of the Society* (p. 110), there is an account of Mr Cook's life-raft, consisting of a square frame with canvass nailed across it, supported by a cask at each corner, for which the gold medal was voted to him. 4. It is followed by a description of Lieutenant Rodger's life-raft (p. 112), which obtained a similar compliment. This raft has the advantage of requiring only such materials as are usually found on board of every ship; capstan bars, boat-masts, yards, or any other spars of moderate dimensions, which are tied together so as to make a sort of waggon frame, with a large cask fixed on each side; it appears to afford a very convenient support to the men, but it can scarcely possess any great strength for resisting the force of the breakers.

---

[1] Emerson's *Mechanics*, fig. 228, 229; Leupold's *Theatrum Machinarium*, plate liv.

Mr J. Bremner, a clergyman in the Orkneys, had received a medal from the Society in 1810, for his method of converting any ship's boat into a life-boat, by putting into it three or four casks attached to the keel, which is to have a ring-bolt fixed in it for receiving the ropes by which the casks are fastened; he gives particular directions for making all the necessary arrangements, in the twenty-eighth volume of the *Transactions* (p. 134); he particularly advises that no use should be made of the natural buoyancy of the cavity of the boat, but that the bottom should be perforated without hesitation, wherever the hole would afford any additional facility for fixing a rope. Captain Manby's jolly-boat, fitted as a life-boat, "at the expense of three pounds," seems to be comprehended among those preparations which are to be made previously to the voyage.

The buckling a soldier's canteen on his breast, as an assistance to enable him to float, belongs to those temporary expedients which may occasionally be employed with advantage. Tying a hat in a pocket-handkerchief, and holding it as a float, has been recommended by Mr Lawson in the *Philosophical Magazine* (vol. xx. p. 362); he advises that the crown of the hat should be held downwards, and observes that a stick may be employed, to enable us to use two or four hats at once; but this method can only be adopted when the accident occurs in very still water.

The first and most obvious *preparation* for enabling a person to float, is the learning to swim. It is well known that swimming is scarcely ever sufficient to enable a seaman to reach the land from a ship that has been wrecked, without some assistance; and many have certainly been drowned from depending too much on their own strength; but for a momentary support, and to afford courage and presence of mind to seek for other aid, there is no question but that the faculty of swimming possesses an inestimable advantage. A boy generally learns to swim by the help of his schoolfellows, better than by any general rules, and more agreeably than in a school of natation; but it may be of some use to observe, that the act of diving to the bottom and re-ascending, in tolerably shallow water, is much more easily performed by a beginner than that of simply supporting himself on the surface; and when he has thus acquired the feeling of the immediate effect of his arms in propelling and sustaining him, he soon finds out the means of employing his feet in their assistance. The art of swimming has, however, been systematically treated by Bachstrom, *Kunst zu Schwimmen*, 8vo, Berlin, 1742; by Thévenot, *Art de Nager*, Paris, 1711; and by Bernardi, *Arte Ragionata del Nuoto*, 2 vols. 4to, Naples, 1794.

It is easy to convince ourselves, by trials in a warm bath, without reference to Robertson's experiments (*Phil. Trans.* 1757), that a substance possessing a very small degree of buoyancy is sufficient to enable the human body to float without effort. In fact, when the chest is fully expanded, the thinnest and most bony person will commonly float in sea-water; but the effort of keeping the chest expanded is as fatiguing as any other muscular exertion; and when the chest collapses, the fattest people may be in danger of sinking, unless they have learned to swim. Sir William Hamilton, indeed, tells us that, in 1783, "a woman of Scilla, four months gone with child, was swept into the sea by the wave" accompanying the earthquake, "and was taken up alive, floating on her back at some distance, nine hours after; she had been used to swim; her anxiety and suffering, however, had arrived at so great a pitch, that just at the time that the boat which took her up appeared, she was trying to force her head under water, to put a period to her miserable existence."

In China, a frame of bamboo surrounding the person is used for a float, and the lightness and strength of this substance must make it extremely proper for the purpose; sometimes also a gourd is tied to a child, to secure its floating in case of accident. The inflated goat-skins used from time immemorial by the Arabs, or the seal-skins employed by the Chilians, have the disadvantage of being easily punctured by a rock or a spar; an objection which is also more or less applicable to all substances containing air; for example, to the air jackets described in Leupold's *Theatrum Pontificium*, published about 1724. A float of a semicircular form was recommended by Ozanam, the author of the *Recreations;* and Bachstrom, in his *Art of Swimming*, proposed to float a troop of cavalry, by fixing cork to the saddles. The cork jacket of Gelacy is described in the *History of the Parisian Academy of Sciences* for 1757, and Lachapelle's *Scaphander*, which is considered an improvement on it, in the volume for 1765. In the year 1764, the attention of the British public was particularly called to the floating powers of cork, by some experiments which were made with cork jackets on the Thames, together with some comparative experiments on air jackets; and Dr Wilkinson, in the *Philosophical Transactions* for 1765, describes some experiments by which he ascertained that about a pound of cork was amply sufficient to enable a man of ordinary size and make to float without effort. It is almost superfluous to enumerate the multitude of trifling variations that have been made in the arrangements of cork jackets and air jackets, apparently for the purpose of exciting a momentary interest, though possibly from the best motives. Mr Bosquet advised a bag of cork shavings to be kept in readiness by each person; the *Seaman's Friend* was composed of two pieces of cork, united by straps; the *Collinetta* was a hollow vessel of copper, divided into cells; a "marine spencer" has been described by Mr Spencer, in the sixteenth volume of the *Philosophical Magazine*, consisting only of a number of old corks, arranged so as to form a girdle; and in 1806, Mr T. C. Daniel obtained a gold medal from the Society of Arts, for the invention of an apparatus of waterproof leather, surrounding the body, which, according to the testimonials he produced, had saved the lives of some persons who had been sailing in a pleasure-boat on a river. In smooth water, it has been suggested that throwing a foot-ball, with a small weight tied to it, to the person immersed, would often afford sufficient assistance; and, with respect to floating, there is no doubt that any of the assistances which have been proposed would be sufficient if they were at hand; but there is another object, to which it is necessary to attend, in cold, and even in temperate climates, that of supporting a temperature compatible with life and health, if the immersion is likely to be of long duration; and an additional provision of worsted stockings, jackets, and trowsers, will be almost as essential, in such cases, as the means of obtaining buoyancy.

For the second object which is desirable to a ship in distress, that of obtaining a safe communication with the shore, it has been usual of late years to rely principally on the humane exertions of persons who may be on the coast, and who may have made preparations for this purpose; and with this view, some instructions for properly co-operating in the measures to be adopted with Captain Manby's apparatus, have been liberally distributed to all ships when they received their papers from some of the

British custom-houses. There are, however, some simple expedients which may be adopted for this purpose by persons on board of the ship; for example, the making a kite with a pocket-handkerchief stretched over a hoop, and causing it to carry a cord to the lee shore, by means of which a stronger line, and at last a hawser, may be drawn by persons standing on the beach. A line may also sometimes be carried on shore by a cask, allowed to drift before the wind; and a bag has been recommended to be attached to such a cask, or to a buoy, in order to act as a sail, and to insure its crossing the surf. Mr Cleghorn was also rewarded, in 1814, by the Society of Arts, for the invention of a buoyant line, having a heart of cork, to obviate the inconvenience which would arise from its sinking and being dragged on the stones under the breakers; but he observes, that in heavy storms there is generally a current along shore, which renders the method almost impracticable. (*Transactions*, xxxii. p. 181.) A Mr Wheatley assures us, in Captain Manby's *Essay*, that his own life, and that of eight other persons, were saved, in 1791, by a lead line, which was carried on shore by a Newfoundland dog that he happened to have on board, when two good swimmers had been drowned in the attempt to swim on shore. It had occurred to Lieutenant Bell, in 1791, that a rope might be thrown from a ship which had struck, by means of a mortar carrying a heavy shot, and upon the principle of the gun harpoon; and he showed the practicability of the suggestion by an actual experiment, in which a deep-sea line was carried to a distance of about 400 yards. (*Trans. Soc. Arts*, xxv. p. 136.) He recommended that every ship should be provided with a mortar capable of carrying such a shot, and observed that it might be placed on a coil of rope to be fired, instead of a carriage. The line was to be coiled on handspikes, which were to be drawn out before the mortar was fired. In 1792 he received a premium of fifty guineas from the Society of Arts (*Transactions*, x. p. 204); and he obtained his promotion in the Ordnance as an acknowledgment of his merits. The shot was to weigh about sixty pounds or more, and the mortar five or six hundredweight. The experiments of the French artillery at Lafere were subsequent to those of Mr Bell, though they have sometimes been quoted as the first of the kind.

It has, however, generally been thought impracticable to manage a mortar with effect under the circumstances of actual shipwreck; and Mr Trengrouse has preferred a rocket, as more easily fired, and as having a smaller initial velocity than a shot, so that the rope would be less in danger of being broken by the impulse. He found that a rocket of eight ounces carried a mackerel line 180 yards, and a pound rocket 212; and in some experiments made under the inspection of the Society of Arts, a rocket an inch and a quarter in diameter carried a cord across the Serpentine River in Hyde Park. The musket is provided with a valve, to prevent the escape of the materials of the rocket, and it is to be fired with a little powder, without wadding. The whole apparatus is packed in a chest, containing from eight to twelve rockets, the musket, a life-spencer, a chair to traverse on a rope, a canvass bag, and a ball of wood to throw to a person swimming. Mr Trengrouse was complimented with a medal from the Society of Arts in 1820. (Vol. xxxviii. p. 161.)

Sect. IV.—*External Means of Escape from Shipwreck.*

The means to be employed by persons on shore, in cases of shipwreck, depend either on projecting a line over the ship, or on the use of a life-boat. Mr Bell had cursorily observed, that a line might be carried over a ship from the shore by means of his mortar; but for the actual execution of this proposal, in a variety of cases, we are indebted to the meritorious exertions of Captain G. W. Manby, whose apparatus, according to the report of a committee of the House of Commons, dated in March 1810, appears "to be admirably adapted to its purpose, and to have been attended with the fullest success in almost every instance." In consequence of this report, Captain Manby was thought worthy of a parliamentary reward; and he afterwards published a description of his inventions, under the title of *An Essay on the Preservation of Shipwrecked Persons*, 8vo, London, 1812. He had previously received a gold medal from the Society of Arts in 1808. (*Transactions*, xxvi. p. 209.) His success makes it expedient to extract from his *Essay* a detailed description of the apparatus, and it will be easy to make it somewhat more intelligible by a slight alteration of the order of arrangement.

P. 21. "The method of affixing a rope to a shot, for the purpose of effecting communication, when projected from a piece of ordnance over a stranded vessel, was at length succeeded in, by introducing a jagged piece of iron, with an eye at the top, into a shell, and securing it by filling the hollow sphere with boiling lead; and in another way, by drilling a hole through a solid ball, and passing a piece of iron, with an eye to it, as before described, to the bottom, where it should be well secured by riveting." (Plate CCCXXIII. fig. 22.)

"To produce the means of connecting a rope to a shot, and prevent its being burnt, and rendering it '*irresistible*' to the powerful inflammation of gunpowder, was the labour of infinite time, and the number of experiments to accomplish it is beyond all possible conception. Chains in every variety of form and great strength breaking, proved that it required not only an elastic, but a closer connected body. At length, some stout platted hide, woven extremely close to the eye of the shot, about two feet in length beyond the muzzle of the piece, and with a loop at the end to receive the rope, happily effected it." (Plate CCCXXIII. fig. 14.)

"This method is certainly desirable, as the rope may, immediately [as] it is required, be affixed to the loop, and applied in service. The form of the platted hide may likewise be woven by twisting it in the manner that the lashes of whips or ropes are spun; there is another method, by passing the rope through a case of leather, taking the greatest care that it is so well secured at the eye of the shot, as to leave no room for the SLIGHTEST PLAY, as is represented by the following BARBED SHOT." (Plate CCCXXIII. fig. 21.)

"When the crews of the distressed vessel are incapable of availing themselves of the benefits arising from communication, they having previously lashed themselves in the rigging to prevent being swept away by the sea, which is repeatedly breaking over them, and when, from long fatigue and the severity of the storm (on which occasions it too frequently occurs), they totally lose the use of their limbs, and are rendered incapable of assisting themselves in the slightest degree—the advantages of this shot are, that, on its being projected over the vessel, and the people of the shore hauling it in, it firmly secures itself on some part of the wreck or rigging, by which a boat can be hauled to the relief of the distressed objects; and by the counterbarbs it is rendered impossible [that it should] give up its hold, or slip, while that part of the wreck remains to which it has secured itself.

"Among the many that have been saved by this shot, the following are testimonials of a few of the cases: We, the crew of the brig Nancy of Sunderland, do hereby certify, that we were on board the said vessel when she was stranded on the beach of Yarmouth, on Friday morning, the 15th of December 1809, and compelled to secure ourselves in the rigging to prevent being swept away, the sea running so high over the vessel. And we do farther declare and certify, that Captain Manby, firing a rope with a hooked shot, securely holding on the wreck, enabled a boat to be hauled from the shore over the surf to our relief, otherwise we must inevitably have perished." This certificate is attested by six signatures.

P. 27.—"Facilitating communication is at all times of importance; but when the stranded vessel is in momentary danger of going to pieces, this point becomes a consideration of extreme urgency. I feel a persuasion that this particular service can only be carried into effect by a small and light piece of ordnance, the range of which is consequently very inconsiderable, when compared with that of a large and heavier piece, as it is weight alone that conveys the rope. In order, therefore, to increase the powers of a shot projected from a small mortar, its natural form must be varied, so as to give it additional 'preponderance.' The following shape, in the form of a pear, has been used with the greatest success; for, by the increased weight, the shot's momentum and power over the line is in consequence considerably augmented in its range; and when made to fit the piece as close as possible, a great increase of velocity is likewise produced from that decrease of windage." (Plate CCCXXIII. fig 11.)

"Portability in the construction of a piece of ordnance (as just described) is the very essence of this service; and communication with the stranded vessel or wreck may be effected with a cord, by which cord a rope can be conveyed, and by that rope a hawser or cable sent to the distressed vessel; for this purpose the following was constructed." (Plate CCCXXIII. fig. 18.)

P. 31.—"A person completely equipped with every necessary apparatus to effect communication with a vessel driven on a lee-shore.....the horseman, fully equipped, travelled a mile and a half, the howitzer was dismounted, and the line projected 153 yards, in six minutes.

"The application of a small piece of ordnance (Plate CCCXXIII. fig. 17) likewise offers particular advantages, capable of being employed from a boat to go to the assistance of a vessel grounded on a bar when running for a harbour, the necessity of which repeatedly occurs, and was twice witnessed at Blakeney on the 10th of November 1810, when boats endeavoured to go to their relief, and were enabled to get out of the harbour on the ebb tide, within twenty yards of the vessel; but it was found impossible to approach them nearer. Had such boats been provided with a piece of this description, and the same firmly secured on a stout piece of plank, by the holes left at each corner of the iron bed, they might have projected a small rope, coiled in a crate or basket made to the form of the bow of the boat, and the persons in the boat, so provided, would not have remained the distressed spectators of the untimely end of their fellow-creatures, without being able to afford them the smallest relief, although so little was then wanted for that desirable purpose."

"Although advantages have been pointed out in the use of these small mortars, it is necessary to be kept in remembrance, that they are produced for particular services, as the nature of the coast, and circumstances attending the distressed vessel, will direct what piece is best adapted to the undertaking. To enable the mind to form a judgment what can be effected by other pieces, the following are the minutes of experiments made with a five and half inch brass mortar, stating the quantity of powder used, and distance the ropes were projected against a strong wind, at the angle of seventeen degrees (elevation): weight of the mortar and bed about three hundred.

Ounces of Powder.	Yards of inch and half Rope.	Yards of Deep-sea Line.
4	134	148
6	159	182
8	184	215
10	207	249
12	235	290
14	250	310

"With a short eight-inch mortar, the weight of which and bed was supposed to be about seven hundred; the angles of elevation uncertain.

Ounces of Powder.	Yards of Deep-sea Line.	Yards of two-inch patent Sunderland Rope, capable of hauling the largest Boat from a beach.

P. 15.—"*Directions for using the Apparatus.* When the rope (which should be pliant and well stretched) is brought on the beach or cliff opposite to the stranded vessel, the most even spot, and free from projecting stones, should be selected to lay it on, and great care be taken that no two parts of it whatever overlay or even touch each other, nor must it be laid in longer lengths than of two yards. But to project a small line or cord, it will be necessary, if it is required, to contract the faker to half a yard at most, to avoid the jerk received at the end of each right line. The best method, with such a description of cord, is to lay it on the ground in the most short and irregular windings, to relieve it from this powerful impulse. To prove the effect of the impulse on a rope, if it is faked in lengths of ten or fifteen yards, it will break each time, as it then becomes a most powerful pendulum. These precautions are absolutely necessary to the success of the service.

"The following has, after various trials, been found a certain method of laying the rope, and placing it into compartments." (*French Faking,* Plate CCCXXIII. fig. 1.)

"A particular attention to this mode will never fail with a good rope, when the impediments are removed that might otherwise obstruct its rapid flight. Its advantages are, that it will allow the eye rapidly (yet correctly, *just before firing,* which is absolutely necessary) to pass over the different compartments, and at once discover if any fake has been displaced by the storm, or by any other casualty or accident come in contact with another part, which would destroy its application by the rope breaking.

"It may likewise be coiled in the manner used in the whale fishery, *whale lair* (Plate CCCXXIII. fig. 5); and in the following method, *chain faking* (Plate CCCXXIII. fig. 4).

"It is, however, necessary to add, that great attention is required in laying it agreeably to the two latter methods, arising not only from the arm being liable to get under certain parts of the rope, and thereby displace it, but from the great anxiety of mind natural on these occasions, where the lives of fellow-creatures are literally dependent on the correctness with which the rope is laid; it is therefore extremely difficult, in a moment of agitation, to determine whether any overlay has taken place, an error that would infallibly destroy every endeavour, and occasion even the fate of those whose lives we might be exerting ourselves to preserve. Could persons in the performance of this service be always collected, the two latter methods would have a decided advantage over the first mode of faking, they being laid in a much less space of time.

"As all these methods of laying the rope occupy time to place it with the care necessary; and as it has repeatedly happened that vessels, very soon after grounding, have gone to pieces, and all hands perished; it was necessary to produce a method of arranging the rope, so that it could be immediately projected as soon as it arrived at the spot; and none proved so effectual as when brought ready laid in a basket." (Plate CCCXXIII. fig. 20.)

"In this case, the rope should be most carefully laid in alternate tiers or fakes, no part of it overlaying, and it should be well secured down, that in travelling it be not displaced. But, above all things, no mistake must happen in PLACING THE BASKET PROPERLY. For example, that the end of the basket, from which the shot hangs in the above plate, should be previously marked, as it is here represented, and must be placed towards the sea or wreck, that the rope be delivered freely, and without any chance of entanglement. It will be scarcely necessary to add, there will be several tiers of the rope when laid. The utmost care and attention are required in laying the rope in tiers with strict regularity, to prevent entanglement."

P. 36.—"The next is the application of the mortar. If the wind is sideways to the shore, it must be pointed sufficiently to windward to allow for the slack of the rope lighting on the object, as the rope will, of course, be considerably borne to leeward by the effect of a strong wind, and by its being laid at a low elevation insures the rope falling against the weathermost part of the rigging. While this service is performing, great care should be taken to keep the mortar dry; nor should it be loaded until every thing is ready; when that is done, it should be primed; but as it would be impossible to do it with loose powder in a storm, a tube is constructed in the simplest manner, of common writing paper (the outer edge being cemented with a little gum) in this form (Plate CCCXXIII. fig. 2.) It is filled with meal gunpowder, made into paste with spirit of wine; when in a state of drying, run a needle through the centre, and take care the whole is left open, for, on the tube being inflamed, a stream of fire darts through the aperture with such force as to perforate the cartridge. The mortar should then instantly be fired; and in order to lessen a difficulty that has often occurred in performing this service, a pistol may be used, having a tin box over the lock, to exclude the effect of wind or rain on the priming; and the muzzle being cut [obliquely], dilates the inflammation, so as to require but little exactness in the direction of the aim.

"We will suppose the communication to be secured, although it is scarcely necessary to offer any other assistance than that of a rope, as the inventive genius of a sailor will supply every thing else; yet I could expect the people on shore to get a boat ready for meeting the vessel when driven on a beach: it is the promptest and most certain method of relief, as well as the most easy to be accomplished; for by hauling her off with the rope projected, the boat's head is kept to the waves, and not only insures safety by rising to the surge, but prevents her upsetting."

Again, p. 59.—"When the rope attached to the shot (not having barbs to it) is fired over the vessel and lodges, let it be secured by those on board, and made fast to some firm part of the rigging or wreck, that they may haul off a boat by it; but should there not be any boat, then haul on board by the projected rope a larger one, and a tailed block, through which a smaller rope is rove. Let the large rope be made fast at the mast-head, between the cap and the top of one of the lower masts, and the tailed block a little distance below it; but, if the masts should have been cut or carried away, then it must be made fast to the loftiest remaining part of the wreck. When this is done, there will be supplied from the shore a cot, hammock, netting, basket, hoop, or any of the numerous resources of seamen, which will run on the larger rope, and be worked by the people on shore. If a cot be used, the men may be so securely fastened to it as to preclude all possibility of falling out, and then be brought from the wreck, one by one, in perfect safety."

P. 47.—"While communication is gaining, three stakes should be driven into the ground in a triangular position, so as to meet close at the heads to support each other. As soon as communication has been effected by the crew of the vessel, and they have secured the line attached to the shot, made fast to these stakes, and the crew will haul on board by it a large rope and a tailed block, through which a smaller rope is to be rove, both ends of which (the smaller rope) are to be kept on shore. When they have secured these on board, and the larger rope is rove through the rollers, let a gun-tackle purchase be lashed to it, then lash the purchase to the stakes. By the means of the purchase, the larger rope may be kept at a fit degree of tension; for, if care be taken to slacken the purchase as the ship rolls out to sea, the danger of the rope being broken will be guarded against; and, on the other hand, if the purchase be gathered in as the ship rolls toward the shore, the slackness of the rope, which would prevent the cot traversing as it ought to do, and plunge it in the water more than it otherwise would, will be avoided." (Plate CCCXXIII. fig. 9.)

P. 59.—"Supposing neither boat nor cot apparatus at hand, first cast off the shot from the projected rope, and with a close hitch, thus (Plate CCCXXIII. fig. 16), let it be put over the head and shoulders of the person to be saved, bringing it close under each arm, drawing it tight, OBSERVING PARTICULARLY THE KNOT IS ON THE BREAST-BONE; for, by having the knot in that position, on the people of the shore hauling the person from the wreck, he will naturally be on his back, consequently, the face will be uppermost to seize every moment for respiration, after each surf has passed over the body. If circumstances compel recourse to this method, care must be taken to free the rope from any part of the wreck, and to jump clear away; but should there be more than one on board, each man should make himself fast in the same way, about four feet from the other, and join hands, all attending to the same directions."

P. 61.—"*For giving Relief to Vessels Stranded on a Lee Shore in a Dark and Tempestuous Night.*. It will be requisite, first, to devise the means of discovering precisely where the distressed vessel lies, when the crew are not able to make their situation known by luminous signals; secondly, to produce a method of laying the mortar for the object, with as much accuracy as in the light; thirdly, to render the flight of the rope perfectly distinguishable to those who project it, and to the crew on board of the vessel, so that they cannot fail of seeing on what part of the rigging it lodges, and consequently have no difficulty in securing it."

"To attain the first object, a hollow ball was made to the size of the piece, composed of layers of pasted cartridge paper of the thickness of half an inch, having a lid on the top to contain a fuze (Plate CCCXXIII. fig. 3), and it was then filled with about fifty luminous balls of star composition, and a sufficient quantity of gunpowder to burst the ball and inflame the stars. The fuze fixed in the ball was graduated, to set fire to the bursting powder at the height of 300 yards. Through the head of the fuze were drilled holes, at equal [distances], to pass through them strands of quick match, to prevent the possibility, from any accident of the match falling out, or from its not firing the fuze.

"On the stars being released, they continued their splendour while falling, for near one minute, which allowed ample time to discover the situation of the distressed vessel.

"During the period of the light, a stand, with two upright sticks (painted white, to render them more discernible in the dark), was ready at hand, and pointed in a direct line to the vessel." (Plate CCCXXIII. fig. 6.)

"A shell, affixed to the rope, having four holes in it, to receive a like number of fuzes (headed as before described), and filled with the fiercest and most glaring composition, which, when inflamed at the discharge of the piece, displayed so splendid an illumination of the rope, that its flight could not be mistaken." (Plate CCCXXIII. fig. 24.)

P. 66.—"*To get a Boat from a Beach over the Surf.* The importance of going to the relief of ships in distress at a distance from the land, or for taking off pilots, was viewed as of the highest consequence by the Elder Brethren of the Trinity House, and offered to my particular attention by several distinguished characters. After numerous experiments to accomplish it in various ways, the mode following was most approved. About forty fathoms of two and a half inch rope, made fast to two moving anchors, was laid out parallel with the shore, at a distance beyond the sweep of the surf; to the centre of this rope was made fast a buoy, of sufficient power to suspend the great rope, and prevent it from chaffing on the sand, rock, or stones, as well as embedding, a circumstance that has rendered it impossible, on a sandy or shingly coast, to heave out an anchor with a rope to it from the shore. As this service should be performed in fair weather (to be prepared for the storm), it may be regulated with the greatest exactness, and should take place at the top of high-water, that the upper part of the buoy may be at the full stretch of its power, and only seen at that time. (Plate CCCXXIII. fig. 8.)

"Should the shore be extremely flat, it will be desirable to place another set at a sufficient distance beyond the first, to insure the operation of this method in any state of the tide."

P. 71.—"The royal mortar being brought to the spot, is to be pointed in the direction for the buoy, and should be laid at a very low elevation, but such as to insure the range; for the more it is depressed, the less slack of rope there will be from the parabola formed in the shot's flight; the basket with the rope ready laid (having a barbed shot to it) is to be placed in the front of the mortar; on its being fired, instantly haul the slack of the rope in, to prevent the effect produced on it by a strong tide. Which being done, let the remainder be gently hauled in, to insure the shot's grappling with the great rope; when that is caught and hooked, a power will be acquired fully adequate to the service. (Plate CCCXXIII. fig. 15.)

"As a cast-iron anchor appears particularly adapted to this method, and would be much cheaper than hammered, the following is a plan of one which the Honourable the Navy Board approved, and allowed me to cast at their expense, for the purpose of making the experiment." (Plate CCCXXIII. fig. 19.)

P. 43.—"When a vessel is in that extreme and perilous situation, driven under a rugged and inaccessible cliff, and in danger of going soon to pieces, the most prompt method I should suggest is, by lowering to the crew a rope with stiff loops spliced into it, at the distance of a foot and a half from each loop, of sufficient size to contain the foot, by which they can ascend as a ladder. (Plate CCCXXIII. fig. 7.)

"This rope ladder is capable of being projected; and one of an inch and half rope was thrown from a mortar 194 yards. It might also, from the simplicity of its structure, be extremely useful in escaping from a house on fire. By making one end fast to the leg of a bed or a table, the person would come down from the window in safety, and with much less difficulty, and quicker, than with the common rope ladder, which is heavier and more unwieldy. It has great advantages when employed in saving shipwrecked men in situations just described, when, from extreme cold, and almost benumbed limbs, it would be impossible for them to climb up a rock, or ascend it even by the aid of a common rope. The holds, thus spliced in, will support both hands and feet."

The Report of the Committee of the House of Commons contains also a paper of instructions for the managers of Captain Manby's apparatus on shore, which are somewhat more minute than the directions published in his Essay. For example (p. 13)—

"If the wind be sideways to the shore, the mortar must be pointed sufficiently to windwards to allow for the slack of the rope lighting on the object, as the rope will, of course, be borne considerably to leeward by the effect of a strong wind."

"The distance your judgment decides the vessel to be from the shore, should regulate the charge of powder as stated in the scale,—taking just a sufficient quantity to clear the object: an attention to this will be more certain of your effecting communication, and guarding against the danger of the rope breaking, or any other circumstance that might prevent the successful performance of the service. The elevation of fifteen degrees is to be preferred, particularly if the wind is sideways, pointing the mortar sufficiently to windward, as the rope would then fall against the weathermost part of the rigging of the stranded vessel."

"When a vessel is driven on shore in the night, you will flash gunpowder as often as convenient on your way; this will animate the crew, and denote to them you are coming to their assistance. On getting to the spot where you have reason to suspect the vessel lies, as you are not able to discover her from the extreme darkness, and if the people on board cannot [make known] their situation by luminous signals or noises (which they will be directed to make if possible), you will lay the mortar at a very high elevation, and fire a light ball."

"Just before you fire (the rope) it would be advisable to let off a blue light to put the crew on their guard, to look out, and be ready to secure the rope. The service can be performed with a carronade."

In p. 15, chap. iv. we have a copy of directions to persons on board vessels stranded on a lee shore, proposed to be delivered to the masters at the custom-house. It is observed, that even snapping a pistol, when the powder is wet, may sometimes afford a signal visible on shore, from the sparks of the steel alone. The other parts of the directions will be easily supplied by those who understand the principles of the proposed mode of relief.

Life-boat.

The last description of the inventions to be considered with regard to the preservation of lives, in cases of shipwreck, is that of life-boats which are of such a construction as to be incapable of sinking even when filled with water. The occasional adaptation of the common boats of the ship to such purposes, by means of empty casks, has been already considered. But the boats now in question are supposed to be kept on shore at proper stations, and manned by active persons, who are in the habit of exerting themselves for the relief of seamen in distress.

Mr Henry Greathead, of South Shields, received a gold medal and fifty guineas from the Society of Arts in 1802, and a parliamentary reward of L.1200, besides further remunerations from the Trinity House, and from Lloyd's Coffee-House, for his invention of a life-boat, which is described in the *Transactions of the Society*, vol. xx. p. 283. The length of this boat is thirty feet, its breadth ten, and its greatest depth about three, besides a general curvature which nearly doubles the depth, as reckoned from the ends; the convexity below being intended to give it a greater facility of turning, and a greater power of mounting on the waves without submersion of the bow, which would increase the resistance, though it would not sink the boat; the breadth is also continued further than usual fore and aft, in order to contribute to the same property. The gunwale projects some inches, and the sides below it are cased with pieces of cork, amounting in the whole to seven hundredweight, which are secured by plates of copper. There are ten short oars of fir, fixed on pins to the gunwales, and a longer oar for steering at each end, both ends of the boat being alike. It is painted white, in order to be more conspicuous; and a carriage is provided, for conveying it over land when required. The description is accompanied by documents of the preservation of two or three hundred men by the boats of South Shields and North Shields, which were built in 1789 and 1798 respectively.

Mr Christopher Wilson received a gold medal in 1807, for a life-boat with air gunwales, which was tried at Newhaven, and was said to be lighter and more manageable than Mr Greathead's. (*Transactions*, xxv. 55.)

"Little is required," says Captain Manby, p. 73, "to establish the importance and advantages that will result from giving every boat the properties of a life-boat, particularly when taken into consideration that it can be produced at a very trifling expense."

To illustrate the method of giving the properties of preservation to any boat, I have selected the representation of a man of war's jolly boat, fitted up to make experiments thereon, by permission of the Honourable Commissioners of the Navy Board. (Plate CCCXXIII. fig. 23.)

"To give it buoyancy, empty casks were well lashed and secured in it. For the advantage of keeping it in an upright position, launching from a flat shore, beaching, and to resist upsetting, it had billage boards of equal depth with the keel, and when a good sized piece of iron or lead was let into or made fast to the keel, if any accident did upset the boat, it immediately regained its original posture. A stout projecting rope, with swellings upon it to increase its elasticity, surrounded the gunwale, served as a fender, and prevented it being stoved in lowering down, or when driven in contact with the vessel it might be going to relieve.

"The boat thus described had the plug out, and was filled with water until it ran over the gunwale, when a crew of four, with myself, tried it in every way, and found, from the buoyant property of the casks, it kept the boat so much above the water's edge, that it was rowed with the greatest ease, and was capable of performing any service required."

Mr J. Boyce, in 1814, obtained a medal for his life-boat and safety buoy, consisting of hollow cylinders made of canvass painted and varnished, and connected with each other. It was tried on a river, and carried a man with safety (vol. xxxii. p. 177); but surely it could not be trusted among breakers on a lee shore. In 1818, Mr Gabriel Bray obtained a silver medal for his invention of a boat filled with air boxes under the seats and along the sides. (Vol. xxxv. p. 172.)

Captain Manby's proposal for throwing ropes from ship to ship in cases of accidents, may easily be understood from the methods which he employs for saving lives in shipwrecks. Mr Thomas Cook's life-buoy is related to the same class of inventions; its object is to preserve the life of a person falling overboard in the night, by means of a floating light; and it obtained him a gold medal from the Society of Arts in 1818. (*Transactions*, xxxvi. p. 121.) He observes that a ship may often have to run half a mile before she can get about and lower a boat, so that it becomes highly desirable to afford a temporary support to the sufferer. The machine consists of two casks, with a pillar between them, carrying a composition of potfire, to be lighted by a lock when the accident happens, and to serve as a rendezvous to the man and the boat. He found that it might be lighted and let down into the water in the short time of five seconds, being always kept suspended in a proper manner between the cabin windows at the stern of the ship. Mr Miller's safety poles for skaiters, and Mr Prior's mode of preventing accidents in descending mines, are mentioned in the *Transactions of the Society of Arts* (vols. xxxii. and xxxvi.); but they do not require more particular notice on the present occasion.

A sketch of the expedients which have been recommended for the preservation of mariners, published in a work entitled *Shipwrecks and Disasters at Sea* (vol. iii. p. 459, Edinb. 1822, 8vo), contains a few further historical details relating to some of the inventions which have been described. (L. L.)

LIGATURE, in *Surgery*, is a cord, band, or string, or the binding any part of the body with a cord, band, fillet, &c. whether of leather, linen, or any other matter. See SURGERY.

LIGATURE is also used to signify a kind of bandage or fillet, tied round the neck, arm, leg, or other part of the bodies of men or beasts, to divert or drive off some disease, accident, &c.

LIGATURE, in the Italian music, signifies a tying or binding together of notes. Hence syncopes are often called *ligatures*, because they are made by the ligature of many notes. There is another sort of ligatures for breves, when there are many of these on different lines, or on different spaces, to be sung to one syllable.

LIGATURES, amongst printers, are types consisting of two letters or characters joined together; as *&*, *ff*, *fl*, *fi*. The old editions of Greek authors are extremely full of ligatures; but the ligatures of Stephens are by much the most beautiful. Some editions have been printed without any ligatures at all; and there was a design to explode them quite out of printing. Had this succeeded, the finest ancient editions would in time have grown useless; and the reading of old manuscripts would have been rendered almost impracticable to the learned themselves.

LIGHT.

SECT. I.—HISTORY OF THE SUBJECT.

The nature and properties of the agent on which vision depends have been objects of philosophical disquisition from ancient times. The earliest speculations which have reached us on this subject are those of Pythagoras, who considered vision as produced by particles continually emanating from the surfaces of bodies, and entering the pupil of the eye. The Platonists, on the other hand, conceived that vision was the consequence of the emission of something from the eye meeting with certain emanations from the surfaces of things; yet, with this very gratuitous hypothesis, the Platonists appear to have detected several properties of LIGHT, especially its propagation in right lines, and the equality of the angles of incidence and reflection when it falls on bright and polished surfaces. The effects of the concentration of the sun's rays by concave specula were certainly known to the ancients; and antiquaries have supposed, that, in this manner, the Romans kindled their *sacred fire;* and thus also it has been alleged that Archimedes destroyed the Roman fleet at the siege of Syracuse.

Aristotle regarded light but as a mere quality of matter; he has some ingenious speculations on the rainbow, and on other luminous meteors. Ptolemy the geographer wrote a treatise on optics, which has perished; but, from some fragments preserved by other authors, he appears to have had distinct ideas on the subject of atmospherical refraction.

A long interval of scientific darkness succeeded his era, until the Arabians began to cultivate the learning of the Greeks, and several of their philosophers treated of optics; but the earliest Arabian work which has reached our times, is the celebrated treatise of Alhazen. In it we find a description of the eye, and the uses of its different parts. The author details many experiments on refraction, both as exhibited in the atmosphere, and as light is modified in passing from one medium to another of different density. He also notices the magnifying power of segments of spheres of glass; a hint from which it has been supposed that the important invention of *spectacles* originated. We also owe to him the idea that single vision, with two eyes, is produced by images painted on corresponding points in each retina; and that stars may be seen by refraction, when they are actually below the horizon: remarkable speculations for the twelfth century.

The work of Alhazen was in 1270 commented on by Vitellio, a native of Poland, who added a considerable number of observations on the refractive power of air, water, and glass, which he reduced into a tabular form. He made some ingenious attempts to explain the phenomena of refraction; and he seems to have conceived the true idea of burning lenses.

Roger Bacon, the contemporary of Vitellio, was undoubtedly acquainted with the magnifying property of segments of spheres, and recommended that small segments should be preferred for such purpose; adding, *et ideo hoc instrumentum est utile senibus et habentibus oculos debiles.* This so plainly indicates the invention of spectacles, that we cannot doubt that it had then been made. We know that they became common in the thirteenth century, and are described by Spina of Pisa in 1313, although we have no absolute certainty of their first constructor.

After the revival of letters, one of the earliest cultivators of mathematics was Maurolycus of Messina, who made optics his study. He proved that the crystalline lens of the eyes of animals converges the rays of light which enter that organ, and transmits them to the retina, in or near which the foci of the lenses are situated. Hence also he inferred, that in persons who are *short sighted,* the defect is owing to the too sudden convergence of the pencil of rays before the retina; and that in those who are *long sighted,* the foci are placed behind that expansion of the optic nerve. Maurolycus, however, did not discover that the images of objects are painted on the retina.

Baptista Porta, the author of *Magia Naturalis,* a Neapolitan of rank, was much addicted to philosophic research; to him we owe the first description of the camera obscura, and its application to the delineation of objects. His work contains many observations on light, some of which are accurate; and though some are now found to be erroneous, his remarks are always ingenious. This subject also engaged the attention of Lord Bacon, who complained that the *form* and *origin* of light had been too much neglected; but his labours in other branches of philosophy diverted his powerful mind to different objects.

The true theory of the rainbow was first given by Antonio, bishop of Spalatro, although he could not satisfactorily explain the cause of the colours.

The next optical discovery of importance was the *telescope,* for which we are indebted to Zacchias Jansen, a spectacle-maker of Middleburg, in Walcheren, in 1590; and this important invention was quickly applied by Galileo to physical astronomy, with brilliant success, crowned by the discovery of the satellites of Jupiter, the structure of the Via Lactea, the phases of Venus, the ring of Saturn, the spots on the sun's disk, and a knowledge of numerous stars unknown to former observers.

The study of light was improved under the auspices of Kepler, who gave an explication of the effect of lenses on the rays, and suggested the form of the telescope now called *astronomical.* He treated of refraction, and discovered, that when light falls within glass at an angle a little above 42°, it is wholly reflected; but his theory of vision is much more important; and he showed that images of external objects are painted on the retina, and appear there inverted, a fact also ably illustrated by Scheiner. The invention of the compound microscope seems also due to Jansen, and dates from the same period.

Perspective was first scientifically treated by Pietro del Borgo, Baldassare Perussi, and Guido Ubaldi. To the second of these is due the detection of the *distance points,* to which all lines making an angle of 45° with the *ground line* are drawn; to the third, the convergence of all parallel lines inclined to the ground line, in a point in the *horizontal line;* and also that a line drawn from the eye, parallel to them, will pass through this point. These principles are the foundation of perspective, which afterwards received improvements from 'sGravesande, and were completed by Brooke Taylor. The true law of refraction is undoubtedly due to Willebrod Snell, or Snellius, professor of mathematics at Leyden. He experimentally showed that the co-secants of the angles of incidence and refraction are always in the same ratio. This discovery, we are assured, on the authority of Huygens, was appropriated by Descartes, who had consulted the papers of Snell, but gave it as his own, under a somewhat different form. The successive labours of Descartes, Kircher, Grimaldi, De la Hire, Hooke, and Huygens, gave to the study of optics a profound scientific character; and the interesting discoveries of that century were crowned by the important researches of our immortal

Newton into the optical properties of light. During the last century, our knowledge of this subject has been steadily progressive, by the labours of a multitude of philosophers, so numerous, that we can afford space for little more than to record the names of some of the most successful inquirers into the mysteries of this subtile agent. Among these, Mairan, Dufay, Mariotte, Boscovich, Euler, Mitchell, Melville, Canton, Bennet, and Lagrange, stand conspicuous; nor must we omit the important fact, illustrated by the labours of Bradley and Roemer, that the velocity of light, from whatever source derived, whether from the sun, the fixed stars, the planets or their satellites, is equal, or that its velocity before and after reflection is the same: a formidable objection to the theory of emission. During the present century, the progress of discovery in this field has been no less brilliant. Very early in it, Dr Thomas Young illustrated the principle of *the interference of the rays of light*, founded on some facts observed by Grimaldi, but first distinctly stated in Dr Young's Memoir in the Philosophical Transactions for 1803, entitled *Experiments and Calculations Relative to Physical Optics;* and his conclusions have been demonstrated beyond all doubt by the researches of Fresnel and of Sir John Herschel. The splendid talents of Laplace, of Poisson, Biot, Arago, Pouillet, Cauchy, Ampère, and Fresnel, among continental philosophers, have especially illustrated the phenomena and theory of light: and in our own country, Sir William Herschel, Young, Brewster, the younger Herschel, Airy, Whewell, have pursued these delicate investigations with singular ability and success. Above all, we must record, as among the most signal triumphs of modern science, the detection and explanation of the *polarization of light*, and the singular confirmation thereby afforded of the theory of its propagation by *undulations.*

SECT. II.—NATURE OF LIGHT.

Notwithstanding this long list of splendid discoveries, the nature of light is still in some degree enigmatical. It is admitted, that the phenomena of vision depend upon the agency of a subtile, extremely attenuated matter, set in motion by the sun and other luminous bodies. Its materiality is inferred from its deflection from its rectilinear course, in passing near various bodies; by its being arrested by certain substances, though it passes freely through others; by its reflection from polished surfaces; by its capability of condensation and dispersion, in passing through certain media; by its producing chemical changes in some compounds; and by its apparently entering into the composition of some bodies, from which it may be again extricated.

Thus far the majority of philosophers are agreed; but two opposite theories have been advanced respecting its propagation, and the mode in which it manifests itself to our senses.

Some maintain that light is a peculiar matter, which is projected in all directions from luminous bodies in a rapid succession of material particles. This theory is sustained by the illustrious name of **Newton**, and has been very generally received; but of late, certain difficulties in the explanation of the recently-discovered properties of light, especially its polarization, have tended to revive the doctrine maintained by Descartes, Huygens, and Euler, viz. that all the phenomena of light depend on the *undulations* of a highly attenuated fluid or ether, universally diffused throughout space, which, while at rest, is inappreciable by our senses, but, when acted on by luminous bodies, is thrown into a succession of waves. Luminous bodies are thus supposed to act on the universally diffused fluid somewhat in the manner that sonorous bodies do on air in the production of *sound.*

It is true, that all the known facts regarding light may be explained upon either hypothesis. It must be owned, however, that the remarkable coincidence of fact with theory, and the facility of explanation, favour the theory of undulations, while it scarcely can be said to involve any greater assumption than the doctrine of direct transmission. Both assume the existence of a subtile fluid; both admit the influence of luminous bodies; and it does not seem more difficult to conceive them acting, by causing an undulation in *the matter of light*, than by projecting it in a rapid succession of particles, the minuteness and velocity of which almost elude the grasp of our imagination.

Whichever hypothesis we adopt, the propagation of light is a process of astonishing rapidity. Astronomers have found, from observations on the eclipses of Jupiter's satellites, that planetary light requires about fourteen minutes to cross the earth's orbit; or, if we adopt the more recent and probably more accurate determination of Bradley, that the light of the sun requires about eight minutes to reach our earth; and, if we reckon the mean distance of the sun to be 94,879,956 English miles, it follows, whether we regard it as an emanation or an undulation, that light must travel with a velocity of about 200,000 miles per second.

It is difficult to form any adequate idea of such enormous velocity; but we may approximate it, by comparing this with the ascertained velocity of a cannon ball. A twenty-four pounder, with the common charge of powder, according to Robins, discharges its ball with an initial velocity equal to 1600 feet per second; yet, if such a ball were to continue this velocity undiminished, it would require about ten years to traverse a space which the light of the heavenly bodies pervades in eight minutes.

This prodigious rate, and the ease with which light can penetrate many solid bodies, have been adduced as arguments against the doctrine of the successive emanation of particles from luminous surfaces; but did not the undulatory theory afford an easier solution of certain recently-discovered properties of light, we should not regard such arguments as conclusive. Now, however, the undulatory theory has been shown to correspond so exactly with known facts, and has even enabled us to predict so exactly what experiment has since confirmed, that it has received the sanction of the greatest names in modern science.

SECT. III.—PROPERTIES OF LIGHT.

Whichever hypothesis be adopted, light must be considered as a material substance, possessed of certain properties, detected by observation and experiment.

1. Light is given out by luminous bodies in all directions, and from every point of the luminous surface. This is proved by its being equally seen from every point of observation.

2. It is divisible into homogeneous, independent portions, like air or water; the smallest portion we can separate is termed a *ray;* and several rays form a *pencil of light.*

3. Light appears to be absorbed by certain bodies, and is again given out by them spontaneously. This property is well seen in the diamond, which, after being exposed to the sun's rays, continues for a short time to shine in the dark. Various artificial *phosphori* do the same, as the Bolognian stone, calcined oyster shells, and the like.

4. All solids give out light when heated between 700° and 800° of Fahrenheit's thermometer, and are then said to be *incandescent.* All liquids that can be heated to that point are luminous, as melted metals; and, if the elasticity of their vapours be repressed, other liquids appear capable of this emission. Gases do not, however, seem to be capable of incandescence, yet the phenomena attending their sudden condensation, when they enter into chemical union,

shows that they contain light. Thus, when a mixture of oxygen and hydrogen is suddenly and strongly compressed, the gases unite to form water, and both light and heat are extricated.

5. Some bodies have the property of arresting the progress of light, and are termed *opake;* others transmit it, and are said to be *transparent.* Yet probably no substance is either perfectly opake or perfectly transparent. Thus, gold is one of the most condensed and opake bodies in nature; yet if we enclose gold leaf between two plates of glass, and examine it by transmitted light, it appears of a decidedly greenish hue; showing the transmission of some light through the metal. On the other hand, the most transparent glass, when viewed in a thick plate, and the most limpid water, when in a deep column, appear greenish.

6. When the rays of light fall obliquely on the surface of all bodies, whether transparent or opake, solid or fluid, they are more or less reflected. Smooth and shining surfaces reflect most light, but the degree also depends on the nature of the reflecting substance: the reflected rays are returned from the surface at an angle equal to the angle of incidence: if the reflecting surface be a plane, the parallel rays that fall on it are reflected parallel to each other.

When the rays are reflected from a concave surface, the reflected rays are more inclined to each other than the incident rays; and if that concave surface be the segment of a sphere, the parallel incident rays will converge to a point in the axis of the mirror half way between its surface and the centre of the sphere of which it is a segment; and this point is termed its *principal focus,* or focus of the parallel rays: if the incident rays be *converging,* they will meet the axis between the principal focus and that centre; if the incident rays be diverging, they will meet the axis in a point between the principal focus and the surface of the mirror. From the immense distance of the sun, all the incident rays may be considered as parallel; and therefore his rays will be condensed into the principal focus of such a mirror, which will in this instance also be that of greatest heat. This is the principle of burning mirrors. When the incident rays fall on a convex mirror, they are all reflected more divergingly, or are dispersed.

The properties of reflected light form the object of the science of *Catoptrics.* See Optics.

We are not, however, to imagine that all the light incident on bright surfaces is reflected. Many curious experiments were made on this subject by Bouguer. The quantity of light returned differs with the inclination of the rays to the reflecting surface. It is generally strongest at small angles of incidence; and the difference becomes excessive when the rays impinge on the surface of transparent fluids with different degrees of obliquity. Metals, from their opacity and splendour, form the best reflecting surfaces; but even pure mercury, perhaps the most perfect of reflectors, does not reflect more than three fourths of the whole incident light.

7. When the rays of light fall on transparent bodies, they are differently affected, according to the angle of incidence. When a ray passes from one transparent medium to another, in a direction perpendicular to their touching surfaces, that ray will pass through them in a straight line; but when the ray passes in a direction oblique to their touching surfaces, that ray will be bent, or will form an angle at their junction.

When the density of a medium is uniform, the rays of light traverse it in straight lines; but in a medium varying in density, like columns of liquids, or the atmosphere, in which density increases with the superincumbent pressure, the passage of the rays will form curves.

When a ray passes obliquely from a dense to a rarer medium, it is bent or deflected *from* a line perpendicular to their touching surfaces. When passing obliquely from a rare to a denser medium, they are bent *toward* the perpendicular. In such instances the light is said to be *refracted.* In the first instance, the angle of refraction is always greater than the angle of incidence; in the latter it is always less. The study of the properties of refracted light constitutes the science of *Dioptrics.* (See Optics).

8. The refractive power of different media is unequal; and when the rays of light pass from one medium to another, it may be measured by the ratio between the *sines of the angles of incidence and refraction;* and the number expressing the ratio between the first and the last is the *exponent* or *index* of the refractive power of that substance.

The refractive power of different substances appears to be nearly in the ratio of their density; but with inflammable bodies, or those containing an inflammable principle, the refractive power is in a ratio greater than their density. It was this law which led Newton to his happy conjecture that *water* and the diamond might contain an inflammable principle; speculations which have been verified by modern chemistry. The same opinion as regards the diamond was long before maintained by Boetius de Boodt. He says that unctuous and fiery bodies are easily united, but will not mix with watery substances; and because the diamond readily adheres to resins, which are of a *fiery* nature, and because, like amber, another fiery body, the diamond, when rubbed, attracts light bodies, the diamond itself must be of an inflammable or sulphureous nature: an argument which he considers as confirmed by that gem being "produced in a hot, sulphureous climate." It is obvious that the deduction of Newton differs widely in its principles from the hypothesis of De Boodt; but the latter must be regarded as a curious instance of a true conclusion derived from unsound premises.

9. If a pencil of light be admitted by a small hole in the window-shutter of a darkened room, through a triangular prism of any transparent substance, the white light will be found to undergo a remarkable change. The rays will be separated in the prism, their image will be enlarged; and, if received on a white screen, will be seen variously coloured. The colours will assume a certain determinate order of juxtaposition; and this appearance is termed the *prismatic spectrum.* This coloured spectrum will then be seen divided into colours, of which Newton enumerates seven; red, orange, yellow, green, blue, indigo, violet. These, it is evident, may be resolved into red, yellow, and blue; for the boundaries of the colours are not well defined, and the compound colours which lie between these may be considered as made up of the intermixture of contiguous rays. These rays are not in equal proportions in the spectrum. If we consider it divided into 360°, the red occupies 45°, the orange 27°, the yellow 48°, the green 60°, the blue 60°, the indigo 40°, the violet 80°; and it is worthy of remark, that this division of the scale of colour is a striking approximation to the divisions of a chord that would give the musical intervals of the octave. But as these colours are not bounded by defined lines, but graduate into each other, it is very difficult to determine their relative extent with tolerable precision. The cause of their separation is the difference of their refrangibility by the prism; the red being the least, the violet the most refrangible; that is, turned from the line of the incident pencil of light. The green ray will be found in the centre of the prismatic spectrum; and hence its index of refraction is considered as the mean refraction of the substance of which the prism consists. Newton employed in his experiments prisms of different substances; but he seems to have taken it for granted, that when the mean refraction was the same, the length of the spectrum was also equal, or that the *dispersive power* of the bodies in that case was equal. He considered that prisms and lenses of all kinds of glass,

and of all bodies, whether solid or fluid, with the same *mean refraction*, possessed also the same *dispersive power*, or formed spectra proportional to their mean refraction. Hence he was led to conclude that "the improvement of the refracting telescope was desperate." This error has, since his day, been detected; and this principle forms the basis of Dollond's admirable invention of the *achromatic telescope*, in which the error of refraction in one species of glass is ingeniously remedied by a correction derived from the different dispersive power of another kind of glass, so adapted to the first as to form with it one object-glass. The difference in dispersive power has now been ascertained in a considerable number of diaphanous bodies; and tables of this difference have been formed from the observations of many philosophers, particularly of Sir David Brewster.

The illuminating power of the different rays of the spectrum is different. Sir William Herschel found, that with a prism of flint-glass, the greatest illumination is towards the middle of the spectrum; the yellow rays affording most light, while the illuminating power, diminishing towards each end of the spectrum, is least in the violet ray. A series of experiments on this subject by Frauenhofer, a late celebrated instrument-maker of Munich, showed, that with the best made prisms, when other light is carefully excluded, the most luminous point is nearer the red than the violet end of the spectrum, in the proportion of one to four; and he states the mean refrangibility to be between the blue and indigo rays. But one of the most curious discoveries of this ingenious inquirer is, that the solar spectrum is traversed by numerous dark lines of unequal thickness, perpendicular to the length of the spectrum, and parallel to one another. These lines require a fine prism for their exhibition, a microscope for their detection, and the exclusion of light, except that of the coloured ray under examination. He counted 590 of these lines in the spectrum; the greatest number of them being towards the most refrangible end of the spectrum.

It is well known that the rays of the sun communicate heat as well as light; but the heating power of the coloured rays is very different. Herschel discovered that the red ray raises the thermometer most; and that the effect diminishes as we approach the other end of the solar spectrum. This is sufficiently striking; but in pursuing his investigations he made another singular discovery, that the point of greatest heat is fully half an inch beyond the red end of the prismatic spectrum. Delicate thermometers were placed in the different rays, and gave the following results:—

In the blue ray in	3 minutes it	= 56° F.
Green	3 ...	= 58°
Yellow	3 ...	= 62°
Middle of the red	2½ ...	= 72°
Outer confines of red	2½ ...	= 73° 5′
Half an inch beyond the red	2½ ...	= 79°

These curious experiments were confirmed by Sir Henry Englefield and Sir H. Davy. The inference from them is, that light and heat are unequally refracted.

The prisms used by these philosophers appear to have been of flint-glass; but Dr Seebeck has since found that the position of the point of greatest heat varies with the nature of the refracting prism. Seebeck found, as Herschel did, that with flint-glass the greatest heat was beyond the red; with plate-glass, in the middle of the red; with sulphuric acid in a hollow thin glass prism, in the orange; with water, in the yellow. The sun's rays would appear to be still more complex. Early in this century, Ritter of Jena found that the rays of the solar spectrum possessed different chemical powers. He found that the salts of silver became soonest black a little beyond the violet end of the spectrum, a little less so in the violet, and still less so in the blue; and Seebeck, in repeating the experiments, found that beyond the violet ray muriate of silver became reddish brown; in the blue, bluish gray; and in the yellow it retained its white colour, or at most had a yellowish tint; it became reddish in the red ray, and even when placed beyond it. These changes might have been attributed to the influence of heating or illuminating power, had not the greatest deoxidating effect been observed where the heat and illumination are the least. Dr Wollaston, who observed these facts about the same time with Ritter, considers the sunbeams as compounded of calorific and deoxidating as well as luminous rays, all with different degrees of refrangibility. But if the experiments of Morichini are confirmed, the sunbeams have also the property of magnetizing steel. About twenty-five years ago he announced this discovery; it was repeated by several persons without success, but Mrs Somervile appears to have succeeded. She covered one half of small sewing needles with paper, in Morichini's method, and exposed the naked half to the violet rays for two hours, when she found that the needle had thus acquired a north pole. The indigo ray produced nearly the same effect, but the effect was feeble in the blue and the green; while, though exposed in the orange, yellow, and red, for two successive days, no magnetism was induced. Similar effects followed when one half of the needle was enveloped in white paper, and the other half, exposed to the rays, was covered with blue or green glass, or with silk of those colours.

10. The facts already noticed respecting the bending of the rays toward the perpendicular, when they pass from a rare to a denser medium, lead to the inference that the disposition of the surfaces of the refracting medium must materially influence the direction of the rays of light which enter and pass through. Accordingly, it is found that if one or both surfaces be convex, the rays are bent toward the axis of the medium. If the medium be spherical, or a segment of a sphere, the ray, falling perpendicularly on its centre, will pass straight through; but all those that fall obliquely on the spherical surface will emerge from the medium in a direction inclined *to* the central ray (which may be considered as the *axis* of the medium), and will cut this axis in some point, which is termed the *refracted focus* of those rays. When the medium has its surfaces forming segments of spheres, it is called a *lens;* and lenses are divided into convex and concave, plano-convex and plano-concave, double convex and double concave, according to the form of their surfaces.

When a lens is nearly or really spherical, optical principles will show, that all the emergent rays will not meet in the same point; those farthest from the axis will meet first. But if the lens be a thin segment of a sphere, with one or both of its surfaces convex, this error will not be very conspicuous, and the emergent rays will meet nearly in one *focus*.

When both surfaces of a lens are *concave*, or when one is concave and the other plane, the emergent rays will be bent *from* the axis. The mathematical demonstration of these facts, their application to practical purposes, and to the explanation of natural appearances, belong to OPTICS; to which article attention is directed.

11. Some crystallized bodies have the property of dividing the rays of light which permeate them into two distinct portions, one of which passes in the ordinary direction, while the other pencil undergoes an extraordinary refraction, passing at some distance from the other. Hence, when any body is viewed through such a crystal in a certain direction, both sets of rays become apparent by giving a double image of the object. This curious property was first detected by Erasmus Bartholin, in calcareous spar brought from Iceland. But this subject was first philosophically investigated with his usual sagacity by Huygens,

who proved that the property of double refraction was not confined to calcareous spar; and it has, since his time, been shown, that all crystals, the primitive form of which is neither a cube nor a regular octahedron, possess this property. Newton attempted to explain this double refraction; but his explanation was not happy. He ascribed it to an original difference in the rays of light, by which some are refracted in the usual manner, while others undergo unusual refraction. Huygens discovered, that when the ray of light was received through the Iceland crystal in any direction but one, it was always divided into two rays of equal intensity; but he remarked with surprise, that when he received the divided rays through a second crystal of Iceland spar, the two portions into which each of them was now subdivided were no longer equally intense; that their relative brightness depended on the position of the second rhomb with regard to the first; and that there were two positions of the second, in which one of the rays vanished altogether. This Newton supposed to depend on the rays having different sides, possessed of different properties, each of which "answers to or sympathizes with that virtue or disposition of the crystal, as the poles of two magnets answer to one another."

This idea was followed up by Malus. He conceived that the molecules of this *polarized light* have all their homologous sides in the same direction; and he expressed this modification of light by the term *polarization*, as he compared the effect produced to the influence of a magnet, which directs the poles of a series of needles all to the same side—an hypothesis which Biot modified by supposing that each molecule of light had one *axis*, similarly placed in each, and all turned in one direction, in a polarized ray; while the molecules were conceived to have a free motion round such axes, by which they could assume different positions according to the attractions and repulsions they experience at the surface of each new medium they traverse. The term *polarization* is not certainly very happy, and it is to be regretted that one more appropriate and less hypothetical had not been employed.

If the rays, thus divided into two pencils by calc spar, be received by a rhomb of the same substance, while the axes of both crystals are in the same direction, no new division of the rays takes place; but if, while the first crystal remains at rest, the second be turned round, by the time it has made one eighth of a revolution the rays will be again subdivided, and four images will be produced. By continuing the motion until the crystal has described one fourth of a revolution, the subdivision will again disappear.

Malus discovered that an analogous effect was produced by *reflection*. If a pencil of rays fall on a polished surface of glass at an angle of 35° 25′, it is reflected at any angle equal to the angle of incidence. If we now place another plate of glass in such a position that the rays reflected from the first shall fall on the second also at an angle of 35° 25′, or when the plane of both reflections coincide, the rays will also be reflected from the second plate: but if the second plate be turned round one quarter of a revolution, so as to make the plane of the second reflection perpendicular to the plane of the first, the whole of the rays will now be transmitted through the second plate: when this plate has described half a revolution, the rays will be reflected as at first; and when it has made three quarters of a revolution, they will again be transmitted, *i. e.* when the planes of reflection are parallel, light is reflected, but when they are perpendicular, it is transmitted—or light in such circumstances can permeate glass in one direction, but not in another. Sir David Brewster, soon after Malus, began a vast series of experiments to determine the angles of polarization of different media, and to investigate the general law which regulates polarization by reflection from transparent bodies, which was crowned with the beautiful discovery that "*the tangent of the angle of polarization is equal to the refractive index*," or that when a ray is entirely polarized by reflection, "*the angles of incidence and refraction are complimentary*." In this sketch it would be impossible to do justice to the investigations and beautiful theoretic deductions of Fresnel, which have combined the whole into an inductive science. We must direct the reader to the article Polarization for his important labours, as well as for the profound researches of Airy, Poisson, Biot, Arago, and Cauchy.

Newton rejected the explanation of double refraction offered by Huygens, because he considered the apparent polarization of the rays of light inconsistent with motions "propagated through a fluid medium;" but this arose from his limiting his ideas of luminous vibrations, as entirely analogous to those of producing sound in air, in which they are propagated in the direction of the advance of the undulations. We owe to the late Dr Thomas Young the first idea of the vibrations being *transverse* to the direction of the luminous wave; an hypothesis which he illustrated by the propagation of the vibrations of a stretched cord put in motion at one of its ends. This happy idea has been shown to be a necessary consequence of the phenomena of the interference of polarized light, if we admit the theory of luminous waves. The subsequent investigations of Arago and of Fresnel have confirmed the speculations of the English philosopher, which have connected and elucidated those brilliant discoveries that have conferred lustre on the names of Malus, Fresnel, and Brewster. See Optics and Polarization.

SECT. IV.—COLOUR OF OBJECTS.

The discovery by Newton of the colours produced by the decomposition of the sun's rays, naturally turned the attention of that profound philosopher to the cause of colour in different objects; and he has delivered a theory of colours, of which we shall now exhibit an outline.

1. Newton regards the colour of natural objects, not as produced by any modification which light undergoes from refraction or reflection at their surfaces, but as something inherent in the rays according to their different degrees of refrangibility. The same degree of refrangibility invariably gives the same colour; and when the rays are fully separated from each other by the prism, he found it impossible to change the colour. Thus he refracted the red ray with prisms, but found its tint unaltered; he reflected it from bodies which in day light had other colours, but still it remained *red;* he transmitted it through coloured media of different tints, he passed it through the coloured rings produced by pressing together plates of glass, but he was unable to convert it into another colour. By condensation or dispersion he could render it stronger or fainter, but still it remained red. Similar experiments on the other rays were attended with similar results.

2. He found, however, that by mingling the different rays of the coloured spectrum, he could produce a sort of intermediate tint: thus the intermixture of the yellow and red rays formed an orange, and that of the yellow and blue, a green. But this effect was only distinctly produced by the intermixture of contiguous rays; if they were far removed from each other in the spectrum, no such effect was produced: thus the orange and indigo rays do not produce an intermediate green.

3. The intermixture of all the rays reproduced white light. Newton reflected a pencil of rays through a prism into a dark room, and then interposing a lens of three feet radius, about four or five feet distance from the aperture admitting the light, he collected the convergent rays upon a paper screen, and obtained an intense spot of white light. By

moving the paper he could easily find the point of perfect whiteness; and, by drawing it farther from the lens, he could reproduce the coloured spectrum in an inverted order, as the crossing rays diverged farther from each other.

If any of the coloured rays were cut off before their convergence by the lens, the image on the paper exhibited colour; and if either of them were made to predominate, that tint was rendered perceptible. Newton endeavoured to show the same with mixtures of coloured powders; and though this method presents mechanical difficulties not easily overcome, and the mixtures only afford a gray shade, yet when these were strongly illuminated by concentrated solar light, they became of a dazzling white: and all coloured objects appeared most splendid in the prismatic rays of their own colour. From these facts he considered the colour of objects to depend on the predominance of the coloured rays they reflect. Thus minium, or red lead, appears red, because it reflects principally the least refrangible rays; a violet appears of the colour so denominated, because it chiefly reflects the most refrangible rays; and what we denominate the colour of an object is merely the hue of the rays which it most copiously returns to the eye.

On the other hand, transparent bodies which have colour, when held between the eye and the light, appear so by transmitting most copiously that ray. Thus, too, we see why a body not quite transparent may sometimes appear of different colours by transmitted and reflected light. Such a body may transmit most copiously the blue rays, and reflect the green ones; as we often find in coloured liquids, and sometimes observe in the crystals of fluor spar, and other mineral substances. This fact is a confirmation of the Newtonian theory of colour; for, were the *colour* inherent in the substance itself, it ought to appear equally by either mode of viewing it.

In transparent coloured liquids the shade often varies with the thickness of the column through which the light is transmitted. Thus a clear red liquid in a conical wine glass appears below of a pale yellowish hue; higher up it seems orange, and only has its full red hue when the column is of considerable thickness. This is owing to the most refrangible rays never being able to penetrate the liquid at all. The remaining part of these rays gives the yellowish colour to the thin film at the bottom of the glass; the separation of part of the yellow rays gives an orange tint to the next film of liquid; and, when the yellow rays are wholly stopped by the thicker column, the red, or least refrangible, come undilated to the eye of the observer, and give their colour to the body of the liquid in the glass.

SECT. V.—RELATION OF LIGHT AND HEAT.

It is well known that light and heat are intimately mixed in the beams of the sun—that some bodies give out both light and heat during combustion—and that a high temperature causes the extrication of light in all bodies, the gases excepted. This intimate relation between light and heat has induced some philosophers to consider them as mere modifications of each other. Certain it is that they have many properties in common. They are capable of reflection, of refraction, of concentration, of dispersion, and of polarization—they radiate between distant objects with great celerity, they penetrate solid bodies very readily, they are absorbed by dark and rough surfaces, are generally reflected by smooth surfaces, and they are capable of subverting some chemical combinations.

These properties show very striking analogies; and the phenomena of the polarization of heat, so well illustrated by Professor Forbes of Edinburgh, have undoubtedly rendered this analogy still more apparent: yet in the present state of our knowledge, it would be rash to pronounce their absolute identity. Their total separation, at least as far as our means of detection extend, in some instances,—the very different substances which permit or retard their progress,—the different manner in which they affect our sensations,—have led some inquirers to the opposite conclusion; and though it may still be true that they are modifications of the same kind of matter, it is safest to content ourselves with pointing out those circumstances in which they differ, as well as their general agreements.

1. Light and caloric are not intercepted by the same substances. If we interpose a plate of thin transparent glass between the face and a bright blazing fire, the intensity of the light has no apparent diminution, but the calorific rays seem immediately arrested; and if we make the experiment with a thin diaphanous plate of ice, they seem absolutely intercepted. Some recent experiments of Professor Forbes, with thin plates of ice, afforded an almost microscopic effect on the galvanometer of Melloni's apparatus; but supposing there was no minute hole in the ice, the difference of the transmission of light and heat through diaphanous ice is sufficiently striking. The same takes place with all other species of terrestrial light, though, as we shall presently see, the calorific rays of the sun instantaneously pervade ice.

2. The rays of caloric are more powerfully reflected from a metallic mirror, even of an imperfect shape, than from the best glass mirror; whereas the latter very powerfully reflects light. Dark and dense solids are very readily penetrated by caloric, though they are totally impervious to light.

3. Light affects the organs of vision in a peculiar manner, without producing inconvenience to that most delicate organ, the eye; but a radiation of heat without light, as from a vessel of boiling fluid, though the rays entering the eye may be so powerful as painfully to affect the eye, does not produce any thing analogous to vision.

In the sun's rays, however, heat and light are so intimately blended, that we cannot entirely separate them. The difference in their refractive power causes a partial separation in the coloured spectrum; but both the heat and light of the sun's rays seem to pervade glass or ice with equal facility. Leslie's photometer, placed behind a sheet of diaphanous ice, is immediately affected by the direct rays of the sun, and a lens of transparent ice will concentrate them, so as to fire combustibles; as was long ago observed by Jan Metius and Descartes, and has more recently been proved by Scoresby. This difference between the calorific influence of the sun and of artificial fires has been attributed to the different initial velocity imparted to the calorific emanations in both cases. This is not improbable; but some have considered the calorific influence of the sun's rays as an effect of the condensation or fixation of light. This was the idea of the late celebrated Leslie, and is the principle of his elegant *photometer*.

SECT. VI.—MEASURES OF LIGHT.

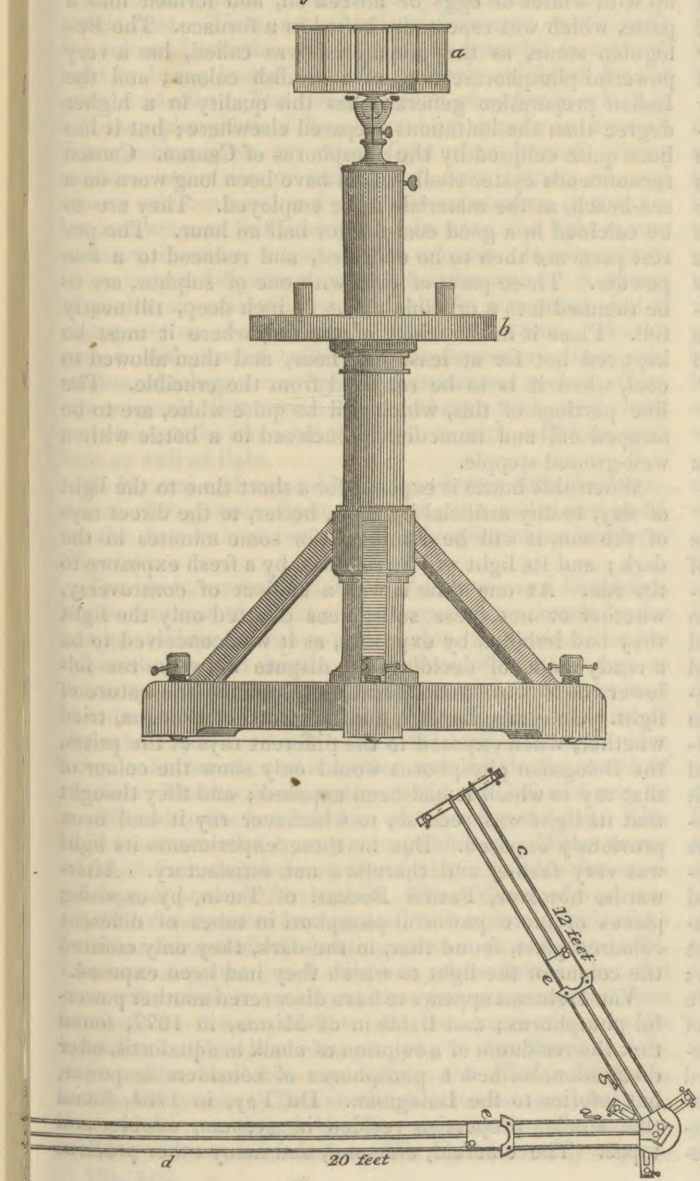
Various methods have been proposed for affording comparative measures of light. The principles of these depend either on the illumination, as ascertained by the distance at which we can distinctly perceive small objects, such as printed letters of a certain size; the comparative depths of the shadows of an opake object; or the heat excited by the luminous emanations of the bodies compared.

1. The distance at which the same eye can read a particular printed paper forms certainly a good criterion of the comparative degree of light given out by two or more luminous bodies, at the moment of comparison; but as it must greatly vary with the goodness of eye, it obviously cannot afford the basis of a general scale of illumination,

by which the same individual can compare his observations at distant periods, or render the experiments of one person comparable with those of another. Still it is a convenient method, and requires but a very simple apparatus; a tube to admit the light in an uniform manner to the paper, and a graduated sliding rule to ascertain with ease the distance of the paper from the eye.

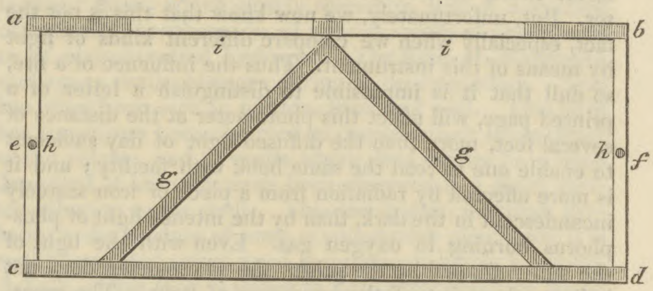
2. The comparison of shadows, which appears first to have been employed by Bouguer among several other ingenious contrivances, was the mode recommended by Count Rumford, who, in 1794, read a paper on this subject to the Royal Society of London. It is reprinted in a volume of his Philosophical Papers, published in 1802. This instrument, though well suited to the object in view, is cumbrous, and somewhat complicated. The photometric part *a* is a box eight inches wide; its back a plate of glass, covered by tissue paper, on which the shadows are projected. It is supported at a convenient height by a tripod-stand. The table consists of two narrow arms *c d*, resting on *b* at one end, and kept horizontal by feet at the other, intended to support the moveable brackets *e e*, on which are placed the lights to be compared. The arms are divided into decimals of an inch; and are here represented on a smaller scale than the rest of the instrument.

Rumford's Photometer.



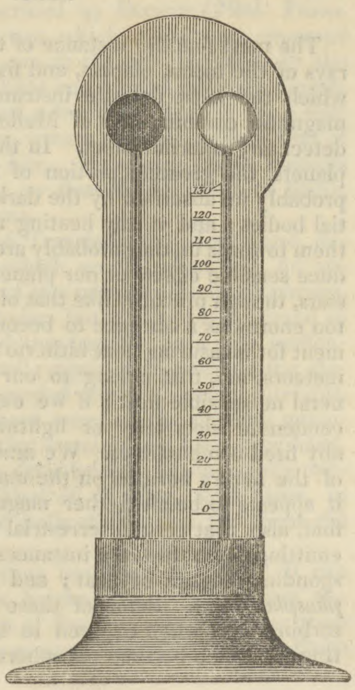
Similar results may be obtained by the following contrivance, proposed, we believe, by Dr W. Ritchie. It consists of a rectangular box of brass, *a*, *b*, *c*, *d*, three inches long, and 2·2 inches wide. In its centre are two plane glass mirrors, *g g*, two inches square, cut from the same plate, and placed accurately at angles of 45° to the base of the box, as in the diagram. Each end *e f* of the box is open, and has, at equal distances from the mirrors, two cylindrical wires of brass, *h*, *h*, 0·2 inch in diameter, fixed vertically in the centre of the box. The top of the box consists of two thin plates of glass, *i i*, on which is pasted tissue paper. The inside of the box and the wires are blackened. When the two lights to be compared are placed before the ends of the box, and in its axis, the shadows of the wires will be reflected from the inclined mirrors on the tissue paper. The adjustments of the lights to the machine may be conveniently made by sliding brackets, placed on a long and steady table. If one of the lights be fixed, the other is to be moved backwards or forwards, in the line of the axis of the machine, until both shadows of the wires shall be of equal intensity. Thus, as the intensity of the light, in such cases, is inversely as the square of the distance of the luminous body, the difference between the position of each light, ascertained either by a graduated fillet on the table, or by a common Gunter's scale, will afford a numerical value of the comparative intensity of each light. The method appears sufficiently accurate for such experiments, but, like the former mode, is not susceptible of a fixed scale, unless we could find some uniform unvarying light to be considered as a standard.

Ritchie's Photometer.



3. The calorific influence of luminous matter was proposed as the measure of the light by Lambert, and was adopted by Sir John Leslie as the principle on which he constructed his photometer. It is the author's differential thermometer, with one of its balls made of black enamel, while the other is of clear glass. An instrument so prepared, when exposed to a heating cause, has its balls unequally heated. To prevent the influence of currents of air, the whole is covered with an air-tight case of transparent glass. The black ball absorbs the calorific rays which impinge on it, the air within it expands, and raises

Leslie's Photometer.



the coloured liquor in the opposite stem of the instrument, to which a scale of equal parts being attached, each equivalent to $\frac{1}{10}$th of a degree of the centigrade thermometer, affords a numerical result; and if we were sure that the intensity of the light is always in proportion to the calorific effect, the instrument would be a perfect photometer. But, unfortunately, we now know that this is not the fact, especially when we compare different kinds of light by means of this instrument. Thus the influence of a fire, so dull that it is impossible to distinguish a letter of a printed page, will affect this photometer at the distance of several feet, more than the diffused light of day sufficient to enable one to read the same book with facility; and it is more affected by radiation from a piece of iron scarcely incandescent in the dark, than by the intense light of phosphorus burning in oxygen gas. Even with the light of the sun refracted by the prism, the photometer does not indicate the point of the maximum of light. The greatest illumination is in the yellow rays; but this photometer rises highest when in or just beyond the confines of the red.

But if we employ the instrument for the purpose chiefly in the view of its ingenious inventor, the measure of the intensity of solar light, this beautiful instrument appears to us the most elegant and useful photometer hitherto proposed. Its delicacy is such, that when freely exposed, in our climate, to the light of the sky, without being acted on by the direct solar rays, it generally ranges in summer from 30° to 40°, and in winter from 10° to 15°. Exposed freely to the sun-beams at noon in summer, it usually mounts to between 80° and 90°; and in the depth of winter is generally about 25°. In the glowing language of its inventor, "the photometer exhibits distinctly the progress of illumination from the morning's dawn to the full vigour of noon, till evening spreads her sober mantle. It marks the growth of light, from the winter solstice to the height of summer, and its subsequent decay through the dusky shades of autumn; and it enables us to compare, with numerical accuracy, the brightness of distant countries—the brilliant sky of Italy, for instance, with the murky air of Holland."

SECT. VII.—EVOLUTION OF LIGHT WITHOUT APPRECIABLE HEAT.

The most familiar instance of this phenomenon is in the rays of the moon, planets, and fixed stars, in the beams of which the most delicate instruments, even the thermo-magnetic combinations of Melloni, have been unable to detect any calorific effect. In the beams of the moon and planets, the greatest portion of the incident light would probably be absorbed by the dark nucleus of those celestial bodies; and if any heating rays were emanated from them towards us, they probably are far too attenuated to produce sensible effects at our planet. The light of the fixed stars, though probably like that of the sun, radiates through too enormous a distance to become sensible to any instrument for measuring heat hitherto contrived. The luminous meteors, too, that belong to our atmosphere, have in general no sensible heat; if we except meteoric stones and condensed electricity or lightning, which has occasionally fired combustibles. We must not confound the effect of the aurora borealis on the magnetic needle with heat; it appears to be altogether magnetic, not calorific. We find, also, that certain terrestrial bodies have the power of emitting light, in some instances largely, without a corresponding degree of heat; and such are usually termed *phosphorescent.* Some of these have the property of absorbing light when exposed to it, and again visibly emitting it. Some become phosphorescent when slightly heated; others give out light during their spontaneous decomposition. Phosphorescence has been examined by Bartholini, Fabricius ab Aquapendente, Bayle, Algarotti, Reaumur, Father Beccari, Father Bourges, Abbé Haller, Seroi, and Canton.

1. Many bodies, when exposed to light, particularly that of the sun, absorb it, and emit it immediately on being removed into a dark place. When a diamond of some size is thus exposed, it has been observed to give out flashes of light in the dark for a short period, and it recovers this property on a fresh exposure. Several other precious stones, some calcareous minerals, almost all animal and vegetable substances, when very dry, or after solution in nitrous acid, and even snow, are stated by Beccari to possess the same property in a greater or less degree. Several artificial compounds, when carefully calcined, have the same effect. This is particularly the case with the *Bolognian stone*, and with Canton's phosphorus. The former is a calcined sulphate of baryta, found at the foot of Monte Paterno, near Bologna. Its properties were first discovered by Vincenzo Cascariolo, a shoemaker of that city, who, from its weight, mistaking it for a metal, attempted its reduction. The inventor kept the process secret, but it seems to have at length transpired: according to Kircher, the stone was reduced to a fine powder, beaten up with whites of eggs or linseed oil, and formed into a paste, which was repeatedly baked in a furnace. The Bolognian stone, as the preparation was called, has a very powerful phosphorescence, of a reddish colour; and the Italian preparation generally has this quality in a higher degree than the imitations prepared elsewhere; but it has been quite eclipsed by the phosphorus of Canton. Canton recommends oyster shells which have been long worn on a sea-beach, as the materials to be employed. They are to be calcined in a good coal-fire for half an hour. The purest parts are then to be collected, and reduced to a fine powder. Three parts of this, with one of sulphur, are to be rammed into a crucible about $1\frac{1}{2}$ inch deep, till nearly full. Place it in the midst of the fire, where it must be kept red hot for at least one hour, and then allowed to cool, when it is to be removed from the crucible. The fine portions of this, which will be quite white, are to be scraped off, and immediately enclosed in a bottle with a well-ground stopple.

When this bottle is exposed for a short time to the light of day, to any artificial light, or, better, to the direct rays of the sun, it will be luminous for some minutes in the dark; and its light will be renewed by a fresh exposure to the sun. At one time it was a subject of controversy, whether or not these substances emitted only the light they had imbibed by exposure, as it was conceived to be a ready mode of deciding the dispute between the followers of Newton and Descartes respecting the nature of light. Galeazzo, Zanotti, and Algarotti of Bologna, tried whether, when exposed to the different rays of the prism, the Bolognian phosphorus would only show the colour of that ray to which it had been exposed; and they thought that its light was reddish, to whichever ray it had been previously exposed. But in these experiments its light was very feeble, and therefore not satisfactory. Afterwards, however, Father Beccari of Turin, by exposing pieces of more powerful phosphori in tubes of different coloured glass, found that, in the dark, they only emitted the colour of the light to which they had been exposed.

Van Helmont appears to have discovered another powerful phosphorus; and Baldwin of Misnia, in 1677, found that the residuum of a solution of chalk in aquafortis, after distillation, formed a phosphorus of considerable power, but inferior to the Bolognian. Du Fay, in 1734, found that similar properties resided in gypsum, marble, and topaz. The emerald, diamond, and many other precious stones, he found to have the same property, without calcination, and by mere exposure to light. From the experiments of Margraaf, all the earthy sulphates have this property when calcined; but he thought that neither metals, metallic ores, nor agates, possess it. The analysis of topaz shows that it contains fluoric acid; and we may now generalize the observation, and state, that all substances capable of becoming phosphorescent by calcination contain some fixed acid, and probably all minerals containing such acids are capable of becoming, in like manner, phosphorescent.

The experiments of Canton are the most complete on this subject (*Phil. Trans.* lviii.). When his phosphorus was, for a short time, exposed to the light of a candle, the moon, or the diffused light of day, it shone for a considerable time in the dark. When exposed to the direct rays of the sun, it gave out light for two hours, at the common temperature of the air. When it had ceased to shine in the dark, the application of heat renewed its luminousness for a short time. If the glass containing the phosphorus be placed in boiling water, its luminousness will be stronger than in the cold, but will last a shorter time. When it has ceased to give light in hot water, it will again give out light on being placed on a hot iron between 400° and 700° Fahrenheit.

2. Some natural bodies become phosphorescent by a gentle heat. Thus, some kinds of fluor spar, particularly the coloured varieties, give out a pure greenish or a bluish light by being heated; and this is finely exhibited by the green varieties. The mineral called *phosphorite*, which is a fibrous phosphate of lime, found principally in Spanish Estremadura, gives out much light when heated. Some marbles, some ores of metals, coal, wax, butter, oil, and several other mineral and vegetable substances, so treated, become more or less luminous. In some the light is momentary, in others it lasts several minutes. It soon attains its maximum brightness, and then fades away. A stream of cooler air extinguishes the light for a moment, but it re-appears on the ceasing of the cool current. Analogous to this class of bodies in some degree are those substances which give out light on percussion; such as siliceous minerals, either with one another or with steel, hard porcelain, or the like; but they also, in such collisions, emit heat as well as light.

3. Mineral and vegetable bodies, during their decomposition, often give out light. Fish, mutton, and rotten wood, are the best known instances of phosphorescent bodies of this class.

The luminousness of fish is well known; and Dr Hulme has shown that the light of herrings and mackerels begins to appear while the fish is still eatable, and soon arrives at its maximum, but begins to decrease when they pass to putridity. To produce this change, the fish should be kept in a dark and cool place. It is not confined to the skin of the animal, for if cut into pieces, the surface of each piece becomes luminous; and it is often seen within the mouth of the fish. The luminous matter easily rubs off, and may be transferred to the hands of him who touches the fish. This light is not attended by any perceptible heat. When scraped off, it forms a gelatinous liquid, that will shine for several days, if preserved in a phial. The addition of fresh water, lime water, water impregnated with carbonic acid, of vegetable acids and alkalies, extinguishes it, as do neutral salts, infusions of pepper, and camphor, when strong; yet the same substances, in a weak solution, seem to promote it, and even render it more durable; but sea-water increases its splendour. This luminous property is also found in lobsters and in shell-fish, especially in the *Pholas Dactylus*, and its congeners. This shell-fish is luminous when quite fresh, and is mentioned by Pliny as rendering the mouths of those who eat it luminous. The light is readily imparted to milk and sea-water, but it is extinguished by spirit, wine, or vinegar. Sea-water, thus rendered luminous, increases in brightness by a gentle heat; but when heated to 133° Fahrenheit, it is suddenly extinguished, and cannot again become luminous. This luminous matter, when narrowly examined, sometimes appears to give out a sort of lambent flame, which closely resembles that of a solution of common phosphorus in oil; and it smells of phosphorus or of phosphuretted hydrogen. The flesh of *Mammalia* undergoes similar changes during its decomposition. This has often been seen in mutton, beef, and veal. This light has sometimes been observed on corpses, much to the terror of the vulgar; and in vaults where dead bodies have been deposited, it has sometimes been observed in a glairy matter adhering to the vault. This last matter, however, probably is the produce of some cryptogamian plant; and it is well known that rotten wood is sometimes highly luminous. A light of this kind is stated to have been observed round the body of a woman at Milan, but it flitted from the bed on the approach of the reporter. This appearance has been more frequently seen around graves, and has obtained in Scotland the name of *elf-candles.*

The light from corrupting animal and vegetable matter requires oxygen in some form for its continuance. It is soon extinguished in the exhausted receiver of the air-pump, as Mr Boyle long ago observed; but it would seem that the small quantity of air which is contained in water is sufficient to sustain its luminousness. No perceptible heat is extricated in any of these kinds of phosphorescence.

Analogous to the light from decaying organized bodies, is the curious meteor termed *ignis fatuus*, or *will-o'-the-wisp.* Its ordinary appearance is like the faint flame of a taper; sometimes it resembles the light of a torch, or a faggot; but it usually recedes as it is approached, and can rarely be observed near at hand. The colour of the light is usually pale bluish, and seems brightest when most distant. It is most frequent in marshy grounds, in churchyards, or where a considerable mass of animal and vegetable putrefaction is going on. Dr Derham once observed an ignis fatuus playing round the head of a dead thistle; and, by cautiously approaching, he got within two or three yards of it, when a slight movement of the air made it flit; and when he pursued it, he was unable to overtake it.

A remarkable appearance of ignis fatuus was, about a century and a half ago, common in the vicinity of Bologna, which has been well described by Beccari (*Phil. Trans.* vii.). He estimated that two, which at that time appeared almost every dark night, one to the east, the other to the north, of the city, gave light equal to an ordinary faggot. One of them accompanied a friend of Beccari for a mile along the road to Bologna, giving as much light as that of the torch carried before him. Sometimes these meteors divided into several parts, or floated like waves of flame, dropping small scintillations.

Dr Shaw, the author of Travels in the Holy Land, describes a remarkable one which accompanied him, for upwards of an hour, in one of the valleys of Mount Ephraim. Its shape was at first globular, but it afterwards spread so as to involve the party of the traveller in a pale inoffensive blaze, then disappeared; again it re-assumed the globular form, and again expanded itself, at certain intervals, over more than two or three acres of the adjacent mountains. The atmosphere that evening had been very hazy, and the dew, as it fell on their bridles, felt unusually unctuous and clammy; a kind of weather, says Shaw, in which sailors observe the balls of fire that flit about the masts and yards of ships.

The cause of ignis fatuus has been disputed. It can scarcely be accounted for by the phosphorescence of the glow-worm, or any species of fire-fly. It differs also from electric flame, but has the greatest resemblance to the flame of phosphuretted hydrogen; a gas which spontaneously inflames, on coming into contact with air, and which is given out during the corruption of organic matter. This gas is absorbable by water and by fatty oils, to which last it imparts its phosphorescent qualities; and perhaps the luminousness of fish may depend on the union of this substance with oily or mucous matter. There is some difficulty in accounting for the appearance so constant and considerable as that described near Bologna. The ground on which the largest meteor appeared is a hard clay, very retentive of water; while in the hilly district, where the Bolognian ignis fatuus was smaller, the soil was a loose sand. Beccari however states, that they chiefly frequented the banks of streams. All accounts confirm the absence of sensible heat from these meteors.

SECT. VIII.—LIGHT EMANATING FROM LIVING ANIMALS.

A luminous appearance somewhat similar to that given out by decaying organic matter is occasionally observed to play round some classes of living animals; and regularly emanates from the bodies of others, at particular seasons; or as a constant concomitant of motion, by another class.

Of the first kind, probably, is that light sometimes observed playing around the ears and manes of horses, which, though by some attributed to electricity, is probably an emanation from the animal itself; and may perhaps consist of a phosphuretted gas, disengaged by some unknown process of the animal economy. A lambent flame, of a similar nature, has in a few instances been remarked around the heads of children; a circumstance which is happily seized by Virgil in his fine description of the glory that appeared on the temples of the young Ascanius.

> Ecce levis summo de vertice visus Iuli
> Fundere lumen apex, tractuque innoxia molli
> Lambere flamma comas, et circa tempora pasci.
> Æn. ii. 683.

Living vegetables, in like manner, also occasionally give out light. This has been particularly noticed in the marigold, the orange, the Indian pink or lilium bulbosum, aconitum napellus, tropœolum majus, &c. But there are animals in whom luminousness forms a necessary part of their economy.

The most familiar instance of this is the common glow-worm, *Lympyris noctiluca*, and its congeners. The male of this species is a *coleopterous* insect, and sports in the air; while the female is *apterous*, doomed for ever to crawl among herbaceous plants, or to nestle on the leaves of shrubs: but when the shades of evening are drawn around, during the summer months, a spot of lucid yellow light, generally tinted with a shade of green, emanates from the extreme rings of her abdomen, and sprinkles the hedges, in some parts of our island, and the warmer parts of Europe, with brilliant stars. The final object of this light is probably to attract the notice of the male insect, who otherwise could with difficulty distinguish his wingless mate. The male of the English glow-worm is generally believed to be destitute of the apparatus for light; though Mr Waller (*Phil. Trans.* for 1684) asserts, that the male of one species of English glow-worm has the luminous appendage. The winged species of glow-worm are common in Italy, Spain, the south of France, and still more so in equinoctial America, in which the flickering light of the numerous fireflies affords a pleasing and interesting spectacle. This light is found to belong to both sexes, though it is most striking in the females.

But the luminous property of the *Fulgora Lanternaria* of South America surpasses that of all animals, in the splendour of its light. It is a large insect, of the order *Hemiptera*, three and a half inches long. It has a sort of thick proboscis, about one inch in length, which is the luminous organ. The light emitted by this species is so splendid that two or three of them will illuminate a chamber.

In all these animals the light has so much the appearance of phosphorus dissolved in oil, that probably it may be a secretion of an analogous nature.

Many animals inhabiting the sea are highly luminous; and it is almost established that the luminousness so often exhibited by the ocean depends entirely upon myriads of minute phosphorescent animals.

This appearance is not constant, but is very frequent in most latitudes, and generally, whenever the night is dark, may be seen exceedingly brilliant around our own coasts. When the water is still, it is seen as numerous bright points of a bluish white phosphorescent light of considerable intensity; but when the water is agitated, as by the waves, the motion of a ship, or the dashing of oars, the light appears often in flashes so intense as to show the hours on a watch, or to render legible the pages of a large printed book. The number of the luminous points varies greatly at different times and in different places; and often in the course of a short sail this fluctuation is very conspicuous. We have observed the coruscations, during a gentle breeze, like a line of fire several hundred yards in length from the bows, or in the wake of the vessel. This appearance is found in every sea, but with some difference in intensity and colour, as it seems to proceed from various genera of animals.

The luminousness of the sea was long ascribed to electricity; but about the beginning of this century it was proved, in many instances, to depend on the presence of animalcules in the ocean, particularly of a minute species of medusa, which abounds in our seas, and seems to be the same as *M. Hemisphœrica* of Müller. Several years before, Sir Joseph Bankes discovered other two animals which rendered the sea luminous, viz. a sort of shrimp, *Cancer Fulgens*, and a large medusa, *M. Pellucens*, both of which abound on the coasts of Brazil.

About twenty-two years ago, the writer of this article made many observations on this subject, both on the coasts of Britain and in the Bay of Biscay. When the water was very luminous in that sea, on several evenings he drew water and carried it for examination into the cabin. Of course it ceased to appear luminous when viewed by candle light, but he could distinguish, floating in a glass of sea-water, a number of pellucid animalcules, which, when magnified by the globular form of the containing vessel, evidently belonged to several species of *Medusaria*, among which he could observe the genera *Noctiluca* of Lamarck, a *Cayanea*, and a *Beroe*. The general size of these animals was from one twentieth to one thirtieth of an inch in diameter. That the luminousness of the sea was derived from these minute animals, appears to be proved by the following simple experiments. Portions of this sea-water were put into separate beer glasses, and the number of animalcules in each was carefully ascertained: they were carried successively to the deck, and when the water was dashed on it, the number of lucid points was ascertained. In most instances the number of these points coincided with the number of animals previously observed in the glass; in no instance were the lucid points *more;* though occasionally they were not so numerous, probably owing to some of them adhering to the glass, or having escaped the shock that stimulated their light-making organs. The same animals he has often observed, even more numerous, in the luminous sea-water of the British coasts; and has obtained similar results by a repetition of the experiments. The luminous points often adhere to the fingers; and on introducing such a luminous speck into a glass of non-luminous sea-water, careful inspection will show a medusary animal floating in the water. The sea-water, on such occasions, if left at rest in glass vessels on deck, or even if suspended in gimbals, would occasionally exhibit luminous points; and the author conceives that the light either attends the voluntary movements of those minute creatures, or is emitted at their will. When sulphuric or other strong acid is poured into luminous water, it will produce a considerable flash of light, either by the effort of the animals to escape, or the unexpected stimulus it produces. In some climates the sea exhibits a fiery-red hue. This has often been observed in the Chinese seas, and in some parts of the Indian Ocean. It is produced, according to the best authorities, by myriads of minute animals that emit a reddish light. Captain Horsburgh and Mr Langstaff have described other kinds of light occasionally observed in the Indian Ocean. The latter mentions, that during a passage from China to New Holland, the sea at night had a faint milky appearance, as if snow had just fallen on the water. The sailors thought it was produced by a coral shoal, but seventy fathoms of line did not find bottom; and when the water drawn up was examined, it was observed to swarm with minute globular bodies, about the size of a pin's head, linked together, and of a milky hue, probably some minute species of medusa. It is well known that the larger fish are sometimes luminous. This has been remarked in the bonito and the shark; but whether they are naturally luminous, or only in consequence of the adhesion of luminous animalcules to them, is not determined.

Some have ascribed the luminousness of the sea to electricity, others to putrescent particles in the water. The former opinion is not probable, from the appearances observed; the latter is supported by the luminous matter of dead fish being diffusible through water, and imparting to it luminous qualities; but the known phosphorescence of many small sea animals, and the coincidence of the number of scintillations, in the experiments above detailed, with that of the animals observed, incline us to believe that the luminous appearance of the ocean depends on the presence of minute animals.

SECT. IX.—CHEMICAL EFFECTS OF LIGHT.

Light appears to be possessed of chemical properties and energies distinct from those of heat, which may be considered as further proofs of its materiality.

It is capable of decomposing various metallic salts. Thus, if a colourless solution of nitrate of silver be exposed to light, it gradually blackens; a powder is deposited which has the same colour, and the salt is found to have lost a portion of its oxygen. This change is more rapidly effected by the direct rays of the sun than by the diffused light of day. The neutral solutions of gold, also, when exposed to light, in contact with charcoal, with vegetable or animal matter, as cotton and silk, are decomposed. This is the principle of the beautiful process invented by Mrs Fulhame, for ornamenting muslin and silk stuffs with flowers and sprigs of gold. The salt of gold parts with its acid and its oxygen to the vegetable or animal matter through the agency of light. The dry salt formed by dissolving gold in nitro-muriatic acid is also slowly decomposed by light under similar circumstances.

Scheele examined the effects of light on metallic solutions, and discovered that the chemical effects of the different coloured rays of the prismatic spectrum were different. By enclosing solutions of silver in glasses of different colours, he found, that in red glass there was very little effect produced, whilst in violet-coloured glass the blackening was speedily produced. These interesting facts were confirmed by Senebier and by Thomas Wedgwood. The latter showed, that in the full sunshine, the blackening of muriate of silver was produced in two minutes, and in the shade that several hours were required to produce this effect. The sunbeams transmitted through red glass have very little blackening effect; yellow and green glass are somewhat more effectual; but blue and violet glass produce the most decisive effects. The discovery of Herschel, respecting the different refrangibility of light and heat, induced Ritter and Wollaston to try the effect upon the salts of silver beyond the violet ray; and they found that the blackening was most decided beyond the visible boundary of the spectrum at the violet end. In some experiments of Senebier, muriate of silver was darkened by the violet ray in 15″, by the blue in 29″, by the green in 37″, by the yellow in 5′ 30″, by the orange in 12′, and by the red in 20′. These effects are wholly due to light; for no effect is produced in the hottest point just beyond the red rays.

Berthollet proved, that during the action of light on many metallic oxides, as those of gold, silver, lead, and mercury, a portion of their oxygen was extricated; and this is supposed to be the change produced in the blackening of the salts of silver,—a partial reduction of the metal. Sir H. Davy found that tritoxide of lead, when moistened, and exposed to the red rays, became red, that is, it lost oxygen, and became a deutoxide. Oxide of mercury, obtained by mixing potash and calomel, was not changed by the most refrangible rays, but became red in the least refrangible rays, which must have resulted from the *absorption* of oxygen. The violet rays produced on the moistened red oxide of mercury the same effect as a stream of hydrogen gas, that is, a deoxidation. Wollaston found that these rays produced an *oxidizing* effect on one vegetable substance, resin of guaiacum. This resin becomes green by absorbing oxygen; and he found that it underwent this change in the violet rays, but again obtained its yellow hue on being exposed to the red rays.

Some of the acids suffer decomposition by light; thus, if we expose colourless nitric acid to the sun's rays, in a flask provided with a bent tube, and terminating in a pneumatic apparatus, the acid becomes coloured, from the formation of nitrous gas, and oxygen may be collected in the trough in the usual way, as Berthollet ascertained. Light also decomposes some vegetable acids, such as the hydrocyanic; and to preserve such compounds pure, it is necessary carefully to exclude light.

Light also in some cases favours chemical combination. If chlorine which has been collected over water, and therefore contains water, be exposed to light, the water is slowly decomposed; its hydrogen enters into combination with the chlorine to form hydro-chloric or muriatic acid, and its oxygen is liberated. The influence of light is still more striking on chlorine and on hydrogen. If we mix equal proportions of these gases, and the access of light be carefully excluded, no action takes place, or their union is very slowly produced; but if we expose them to the diffused light of day, combination will take place in a quarter of an hour. If exposed to the direct beams of the sun, the union is instantaneous, and with a violent explosion. Davy found that when such a mixture was exposed to the red rays only, the gases united without explosion, yet more rapidly than when exposed to the violet rays; but that the conversion of a solution of chlorine into muriatic acid took place most readily at the most refrangible end of the solar spectrum.

SECT. X.—EFFECTS OF LIGHT ON PLANTS.

The change produced on vegetable colouring matter by light is familiar in the process of bleaching by exposure to the sun. But the influence of light on living vegetables is much more remarkable.

If a plant grow in total darkness, its natural green hue is not acquired; but it will be white, though in other respects vigorous. This is familiar in the *etiolation* or blanching of certain garden-stuffs, as celery, sea-kale, endive, &c. The late Professor Robison, many years ago, remarked that plants growing in darkness were not only white, but that they did not attain the natural form of their leaves, nor their natural odour. In descending into a coal mine, he accidentally met with a plant growing luxuriantly, the form and qualities of which were entirely new to him. The sod on which it grew was removed, potted, and carefully attended to in his garden. The etiolated plant languished and died; but the roots speedily threw out vigorous shoots, which, from the form of the leaves, and peculiar odour, he readily recognised as common *tansy.* He repeated similar experiments upon plants of lovage, carvi, and mint, with analogous results.

The green colour of vegetables, and even the form of their leaves, are materially influenced by light.

Some experiments of Senebier would lead to the conclusion that it is the violet end of the spectrum which has the greatest influence in counteracting the effects of *etiolation.* This production of the dark colour of plants would appear to depend upon the decomposition of carbonic acid by the living vegetable, when acted on by light, and the fixation of its carbon. That light is necessary to this process, is proved by the experiments of Priestley, Senebier, Ingenhouz, De Saussure, Davy, and many vegetable physiologists. Growing plants in sunshine give out oxygen by the decomposition of carbonic acid; but in darkness carbonic acid is evolved; and Ellis has demonstrated, in his interesting essays, that oxygen, under such circumstances, always disappears from the air in which vegetation is going on. Light, then, acts an important part in the vegetable economy, by fixing the most dense and abundant of the three general elements of vegetable matter. The influence of light in maturing fruits is well known. The fruits which when ripe are saccharine, are previously *acid;* that is, their hydrogen and carbon are combined with an excess of oxygen. Light, by favouring the evolution of oxygen, and the fixation of carbon, converts the vegetable acid into sugar, and thus provides a suitable food for the embryon in the seed. On the other hand, the influence of light is not less conspicuous in another class of vegetables. In an early stage of the germination of seeds yielding farina when ripe, the tender rudiment of the seed is enveloped in a slightly saccharine juice, as may be seen in young wheat and maize. Now, what is wanted to convert them into farina is the evolution of oxygen, and the fixation of a larger quantity of carbon. These two indications are fulfilled by the influence of light on the growing vegetables; and thus we can explain why the sun's influence is so essential in the one case to the formation of sugar from an acid; and in the other, of farina from a saccharine juice. The same principles will explain why a farinaceous seed, when planted in the ground, becomes again saccharine. Light is now wanting; oxygen is absorbed, and partly aids in the evolution of the redundant carbon, partly is added to the two other general elements. This view affords an instance of the important agency of light in vegetation, and a beautiful example of the simplicity of the means employed to produce diversified effects in the works of creation.

SECT. XI.—EFFECTS OF LIGHT ON ANIMALS.

The facts noticed in the last section show the powerful influence of light on vegetable forms. But its effects on the exterior of animals, though less striking, are not unimportant.

1. The influence of the sun's rays in deepening the colour, or in giving a brown tint to the skin, seems to be more due to the light than to the heat of the sunbeams; for the parts of the skin covered by the clothes, though kept thus hotter than the parts exposed, do not undergo this change. The pale visage and enfeebled vitality of those who live much in obscure apartments, in prisons, and in mines, are well known; and though probably the most violent symptoms that characterize the *anhæmia* of miners, in which the skin assumes a yellowish, waxy hue, and the lips become bloodless, be chiefly due to breathing a vitiated atmosphere, yet some influence is certainly attributable to want of light. The anhæmia of persons long confined in dungeons has often been remarked, and was lately described as strikingly exemplified in the person of Caspar Hausser, the young man whose mysterious birth, confinement, and assassination, have hitherto baffled conjecture.

In climates where the heat renders a state almost approaching to nudity desirable, all travellers agree that the development of the human frame is early, and the form has fewer deviations from the symmetry natural to the race than among northern nations. Deformity is said to be comparatively rare in hot climates, where the surface is much exposed; and this has been attributed by Dr Edwards in some measure to the influence of light. Perhaps, after making due allowance for the less chance of rearing sickly or deformed children among barbarous nations, and for the prevalence of infanticide among them in such cases, there is considerable justice in his remarks on this subject; without which it would be difficult to account for the fine muscular and rounded forms so often observed among nations agreeing in nothing except in the prevalence of a very free exposure of their persons to the full influence of light; as among the Mexicans and Peruvians, the Chaymas and Muyscas of South America, the Caribbs of the Antilles, the inhabitants of the numerous groups of the South Seas, or the free inhabitants of Africa. Probably, too, a part of the effects attributed to country air, in restoring to health the sickly child of the city artizan, is due to *insolation,* or the exposure to light, which appears to have the property of invigorating the vital functions, and of elevating the spirits of those who have suffered a long deprivation of its cheering influence.

2. The effect of light on the lower animals is more marked, and is strikingly illustrated in the curious experiments of Dr W. F. Edwards upon the spawn of frogs. He enclosed portions of the spawn of the frog in different vessels permeable to water, some of which were perfectly opake, while others freely admitted light; the temperature was the same, yet the eggs exposed to light came to maturity; but those deprived of light were not hatched.

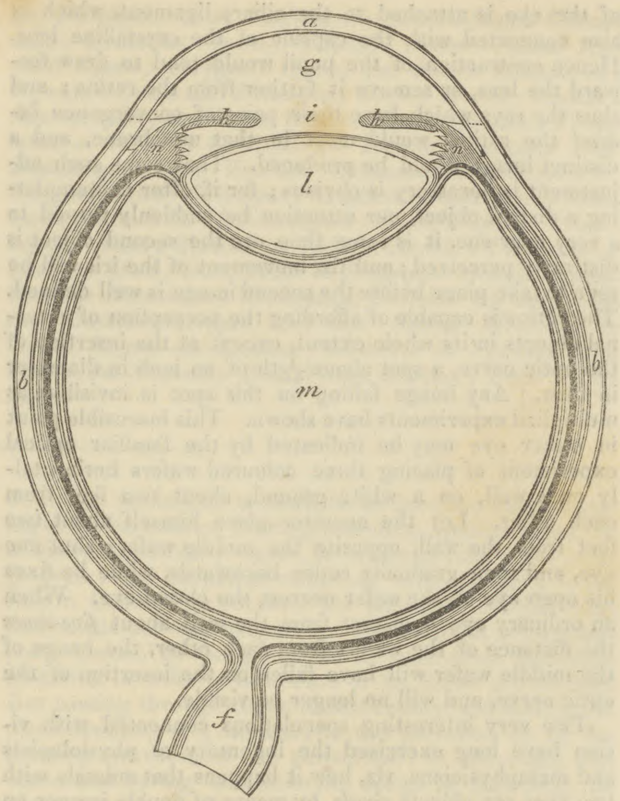
He even found that the development of the perfect form of such animals depended on light. By enclosing tadpoles of both frogs and toads in different boxes, some of which freely admitted light, while others totally excluded it, and placing them in running water, he found that the tadpoles exposed to light underwent the change to the perfect form of the animal, as usual; while the tadpoles excluded from the light, though they seemed perfectly vigorous, did not undergo the transformation, even though they had increased to double or triple their primitive weight. He also conjectures that the Anguine Syren, *Proteus anguinus,* may only be the larva of some reptile retained in its imperfect form by the profound obscurity of the subterranean lakes of Carniola, in which it is found. In this conjecture, however, he is mistaken; for that singular animal has been kept alive without change a considerable time, under circumstances favourable to its transformation, if really an imperfect species, by various naturalists; particularly, as we have been informed, by the Austrian archduke John; and also by Mr Melly, a zealous naturalist now resident in Liverpool.

The facts, however, already detailed, show that the influence of light on the animal economy is by no means inconsiderable. But the most interesting property of light, in relation to animals, is its effect in producing vision.

3. The rays of light emanating from bodies, or reflected from their surfaces, are destined to impress the sensorium through the EYE; an admirable and complex optical apparatus, in which the rays, after passing through the transparent *cornea, a,* sustain various refractions, until they reach the sentient expansion of the optic nerve, *f,* called *retina.* The cornea constitutes the front of the eyeball, the rest of its surface is formed of a dense white tunic, called the *sclerotic coat, bb,* which joins the cornea by its edges, forming with the latter an almost globular body, which contains the more delicate structures of the eye. Just within the cornea is observed a coloured ring, apparently formed of diverging fibres, termed the *iris, hh.* This ring is perforated by the *pupil,* a circular aperture in its centre, which is capable of contraction and expansion, by the action of the fibres of the iris, according to the increase or diminution of the light. This movement of the pupil is not under the will of the animal, but is regulated by the stimulus of light, so as to exclude a quantity that would be hurtful to the organ. The iris is attached to the outer coat of the eye, the sclerotic, by the *ciliary processes, nn.* Within the sclerotic lies a delicately thin vascular membrane named the *choroid coat,* having its interior surface lined with a black secretion termed the *pigmentum nigrum,* the probable use of which is to aid clear vision, by preventing a multiplicity of reflections in the bottom of the eye.

Still nearer to the centre of the eye lies the *retina,* which is continuous with the optic nerve, *f,* and is the part of the eye sentient to the impressions of light. Entering the bottom of the eye, but not just in its axis, is seen a thick cord, the *optic nerve,* by which the impressions upon the retina are conveyed to the brain.

The bulk of the eyeball is made up of three substances, which have been improperly termed *humours.* The first lies just within the cornea, and fills the space between it and the iris, as well as the smaller space immediately behind the latter. From its fluidity, it is termed the *aqueous humour, g.* The iris divides the chamber of the aqueous humour into an *anterior* and a *posterior portion.* The posterior wall of this chamber is formed by a delicate, transparent, capsular membrane, enclosing a lenticular body, convex on both sides, though more so posteriorly, which is named the *crystalline lens, l.* This body consists of concentric layers, formed of fibres externally less consistent, but increasing in density towards its centre; a structure intended for the purpose of correcting its *spherical aberration.* The capsule of the crystalline lens is retained in its situation by the *ciliary circle* or *ciliary processes;* and it lies imbedded in the most considerable of all the humours of the eye, the *vitreous, m,* which consists of a clear gelatinous substance, that recent anatomical investigations prove to be lodged in very delicate membranous cells. In the healthy state, especially in young persons, these humours are perfectly colourless and transparent, but they become coloured by age; and the crystalline lens has been seen in very old persons of a bright amber colour, though still transparent. Opacity of the lens forms the disease termed *cataract.* The obvious use of the humours of the eye is to refract the rays of light entering the eye by the transparent *cornea,* and to concentrate them on the *retina.* The difference in their consistence seems intended to make that organ a true and nicely adjusted achromatic optical instrument.



The ray from any object falling directly in the centre of the eye, perpendicular to its surface, will not undergo any refraction, but pass straight through to the retina; and its direction may be termed the *axis of the eye.* All the rays which fall obliquely on the eye will, by the refraction of the humours, be bent from their course, and cut the axis somewhere between the lens and the retina; and the refractive power of the humours is such as to converge on the retina all rays proceeding from any one point of a visible object, whether these rays fall on the cornea in a parallel or a diverging condition. But as these rays have all crossed the axis of the eye by the refractive power of the humours, it is obvious that the rays from the upper part of the object will impinge on the lower part of the retina, and those from the lowest point, on the upper part of that membrane. Hence the image of the object will be *inverted* on the retina. That this actually takes place we can easily satisfy ourselves, by removing from the posterior part of the eye of a sheep a portion of the sclerotic coat with a sharp knife, until it becomes translucent, when the image of a candle placed before the cornea will be seen inverted on the back part of the eye thus prepared.

In the usual state of the eye, its refractive apparatus is so contrived that all the rays from the same points of objects at some distance from the eye will *converge in the retina,* or the *principal focus of the eye will lie in that membrane;* but divergent rays from very near objects would converge in a point *behind the retina,* were there not some power of adjustment in the eye for correcting the confused image which would thus be formed. This may be effected in two ways; either by increasing the convexity of the cornea, or by bringing the lens to a greater distance from the retina. Some have attributed this adjustment to an alteration in the form of the eyeball, and consequently of the cornea, by the action of the motor muscles of the organ; but there is much more probability in the opinion that this adjustment is produced by the contractions and expansions of the *iris.* This part of the eye is attached to the ciliary ligament, which is also connected with the capsule of the crystalline lens. Hence contraction of the pupil would tend to draw forward the lens, or remove it farther from the retina; and thus the rays which have their point of convergence *behind* the retina, would meet in that membrane, and a distinct image would be produced. That some such adjustment is necessary is obvious; for if, after contemplating a distant object, our attention be suddenly turned to a very near one, it is some time ere the second object is distinctly perceived; and the movement of the iris will be seen to take place before the second image is well defined. The retina is capable of affording the perception of external objects in its whole extent, except at the insertion of the optic nerve, a spot about $\frac{1}{40}$th of an inch in diameter in man. Any image falling on this spot is invisible, as multiplied experiments have shown. This insensible point in either eye may be indicated by the familiar optical experiment of placing three coloured wafers horizontally on a wall, on a white ground, about two feet from each other. Let the operator place himself about two feet from the wall, opposite the middle wafer; shut one eye, and then gradually retire backwards, while he fixes his open eye on the wafer nearest the closed eye. When an ordinary eye is distant from the wall about *five times* the distance of the wafers from each other, the image of the middle wafer will have fallen on the insertion of the optic nerve, and will no longer be visible.

Two very interesting speculations connected with vision have long exercised the ingenuity of physiologists and metaphysicians, viz. how it happens that animals with two eyes see objects *single*, by means of double images on the retinæ; and how they appear *erect* by means of inverted images?

The first has been explained on the supposition of there being corresponding points in each eye that convey similar perceptions to the mind, and that such afford only the idea of *unity*. In the natural movements of the eyes, the images of external objects are supposed always to fall on such points; but should any cause throw the images on dissimilar points, then we have double vision. Hence, if with the finger we push one eyeball slightly out of its parallel position with regard to the other, two objects are perceived. In persons who squint, the parallel movement of the eyes is lost; and it has been supposed that in cases where the squinting has come on in adults from imperfection in one eye, that habit enables the individual to correct the illusion of double vision, and that the person ceases to notice the impressions made on the least perfect of the two eyes.

The second fact alluded to is that of *erect* vision by *inverted* images. That images of external objects are depicted inverted on the retina is perfectly well ascertained; and philosophers have been much puzzled to explain how the indications of vision and touch are reconciled. Some have imagined that at first we really see objects inverted, but learn by experience and by the sense of touch to correct the illusion. Other attempts have been made to explain it by what has been termed the *law of visible direction;* by which it is supposed that when any point of an object is viewed, the rays proceeding from that point must fall on the eye with different degrees of obliquity, yet that point will be only seen in the direction of the central ray of the cone of light proceeding from that point: And as the lines of *visible direction* must necessarily cross each other at the centre of visible direction, those of the lower part of the image on the retina must go to the upper part of the object, and those of the upper part of the image to the lower part of the object; and hence an erect object is considered as the necessary result of an inverted image.

This is very ingenious, but it is obviously hypothetical and obscure. The physiological explication of single vision by double images suggested by Newton, and since supported by Wollaston, is based on what has been termed the *semi-decussation* of the optic nerves at their commissure, whereby the right half of the retina of each eye is placed in direct nervous communication with the right optic lobe, or right half of that part of the brain termed *corpora quadrigemina*, and *vice versa.* Hence impressions made on corresponding points in each retina may, in fact, be impressions on the *same points of the common sensorium*, and therefore co-operate in producing the same perception. The anatomical proof of this is still defective, but many facts give it probability. The subject has engaged the attention of Professor Alison of Edinburgh, who considers that this arrangement of the optic nerves is but a part of the provision by which nature has secured harmony between perceptions afforded by sight and touch. His explanation of one of the most perplexing questions in animal physiology is so ingenious, that we gladly avail ourselves of his permission to lay it before our readers.

According to him, the peculiar contorted or involuted course of the optic nerves (in all vertebrate animals) around the crura cerebri, until they are lost in the optic lobes, seems designed to secure that the position of the *impression on the sensorium* should be conformable to the true position of the object.

It is only in those animals intended by nature to contemplate objects with both eyes at once, as in mammalia and birds, that the semi-decussation of the optic nerve is found. The contrivance in fact implies that both eyes are to be at the same time directed to the same object, or that both optic lobes are to be constantly employed in vision at the same time; the right half of each retina being in connection with each optic lobe, and the left half of each retina in like manner connected with the left optic lobe. Now, the *right* half of each retina contains the image of the *left* half of the field of vision; and therefore the impressions made by the left half of the field of vision fall on the right optic lobe, and have, on their left, the impression resulting from the right side of the field of vision; on which, as both optic lobes are necessarily exercised together, the attention of the mind is equally directed.

Dr Alison considers that the grand contrivance adopted by nature to secure harmony between the indications of sight and touch is the *decussation at the pyramids* of the nervous fibres concerned in common sensation and in voluntary movements; the effect of which must be, that while the right side of the brain is that to which impressions from the left half of the field of vision are brought, it is also *that* on which all the other sensations of the left side of the body depend; or, in other words, *we both see and feel what is on our left by the right side of the brain.* Accordingly, it is in those animals only in which the semi-decussation of the optic nerves exists (namely, in *Mammalia* and birds) that the decussation at the pyramids exists, or that the sensations and voluntary motions of each side of the body appear to be in connection with the opposite side of the brain.

As the admirable mechanism of the eye, and its beautiful adaptation to the necessities and comfort of the animal creation, afford a striking instance of that wisdom and beneficence so conspicuous in the handywork of the Deity; so the extinction of this exquisite and important organ must be considered as one of the severest of human calamities; a misfortune that perhaps cannot be fully appreciated by those who have not experienced the loss of sight, so feelingly deplored by our mighty bard in poetry that can only perish with the language in which it is expressed.

Thus with the year
Seasons return, but not to me returns

Day, or the sweet approach of even or morn,
Or sight of vernal bloom or summer's rose,
Or flocks, or herds, or human face divine;
But cloud instead, and ever during dark
Surrounds me, from the cheerful ways of men
Cut off, and for the book of knowledge fair
Presented with an universal blank
Of nature's works, to me expunged and raz'd,
And wisdom at one entrance quite shut out.

Light-Horse, an ancient term, signifying an ordinary cavalier or horseman lightly armed, in opposition to the men-at-arms, who were heavily accoutred, and armed at all points.

Light-House, a building erected upon a cape or promontory upon the sea-coast, or upon some rock in the sea, and having on its top in the night-time a light, such as to be seen at a great distance from the land. As the British light-house system is at present under the consideration of parliament, we feel that it would be premature and unsatisfactory to give any article under this head; and we are therefore under the necessity of referring to another, viz. that of SEA-LIGHTS, where the whole subject will be fully discussed.

Light-Room, a small apartment, enclosed with glass windows, near the magazine of a ship of war. It is used to contain the lights by which the gunner and his assistants are enabled to fill cartridges with powder to be ready for action.

LIGHTER, a large, open, flat-bottomed vessel, generally managed with oars, and employed to carry goods to or from a ship when she is to be laden or delivered. There are also some lighters furnished with a deck throughout their whole length, in order to contain those merchandises which would be damaged by rainy weather. These are usually called *close lighters.*

LIGHTFOOT, JOHN, a learned English divine, was the son of a divine, and born in March 1602, at Stoke-upon-Trent, in Staffordshire. After having finished his studies at a school on Morton Green, near Congleton in Cheshire, he was removed in 1617 to Cambridge, where he applied himself to the study of eloquence, and succeeded so well as to be thought the best orator among the under graduates in the university. He also made extraordinary proficiency in the Latin and Greek, but neglected the Hebrew, and even lost that knowledge of it which he brought from school. His taste for the oriental languages was not yet excited; and as for logic, the study of it, as conducted at that time among the academics, was too disputatious and fierce for his meek disposition. As soon as he had taken the degree of bachelor of arts, he left the university, and became assistant in a school at Repton in Derbyshire. Having held this situation a year or two, he entered into orders, and became curate of Norton-under-Hales, in Shropshire. This curacy occasioned an awakening of his genius for the Hebrew tongue. Norton lies near Bellaport, then the seat of Sir Rowland Cotton, who being his constant hearer, made him his chaplain, and took him into his house. This gentleman, being a perfect master of the Hebrew language, engaged Lightfoot in that study; and, by conversing with his patron, he soon became sensible, that without that knowledge it would be impossible to attain to an accurate understanding of the Scriptures. Having, therefore, applied himself to it with extraordinary vigour, he in a little time made great progress; and his patron removing with his family to reside in London, he followed his preceptor to that city. But he did not stay long there; for, having a mind to improve himself by foreign travel, he went down into Staffordshire, in order to take leave of his father and mother. But passing through Stone in that county, and finding the place destitute of a minister, he was prevailed on by the pressing entreaties of the parishioners to undertake that cure; and having laid aside his design of travelling, he began to turn his thoughts to settling at home. During his residence at Bellaport, he had made the acquaintance of a gentlewoman, the daughter of Mr William Crompton of Stonepark, and being now in possession of that living, he married her in 1628. But notwithstanding this settlement, his unquenchable thirst after rabbinical learning would not suffer him to continue there; and Sion College library at London being well stocked with books of that kind, he quitted his charge at Stone, and removed with his family to Hornsey, near the city, where he gave the public a specimen of his advancement in those studies, by his *Erubbim, or Miscellanies Christian and Judaical*, in 1629. He was at this time only twenty-seven years of age, and appears to have been well acquainted with the Latin and the Greek fathers, as well as the ancient heathen writers. These first fruits of his studies were dedicated to Sir Rowland Cotton, who, in 1631, presented him to the rectory of Ashley, in Staffordshire.

Considering himself as now fixed for life, he built a study in the garden, to be out of the noise of the house, and applied himself with indefatigable diligence in searching the Scriptures. Thus employed, the days passed agreeably; and he continued quiet and unmolested, till the great change which happened in public affairs brought him into a share of the administration relating to the church; for he was nominated a member of the memorable assembly of divines for settling a new form of ecclesiastical polity. This appointment was the effect of his distinguished merit; and he accepted it solely with a view to serve his country, as far as lay in his power. The non-residence which this would necessarily occasion, apparently induced him to resign his rectory; and having obtained the presentation for a younger brother of his own, he set out for London in 1642. Having now satisfied himself in clearing up many of the most abstruse passages in the Bible, and provided the chief materials, as well as formed the plan, of his *Harmony*, an opportunity of inspecting it at the press was no doubt an additional motive for his going to the capital, where he had not been long before he was chosen minister of St Bartholomew's, behind the Royal

Lightfoot.

Exchange. The assembly of divines having met in 1643, our author attended diligently there, and made a distinguished figure in their debates, where he used great freedom, and gave signal proofs of his courage as well as learning, in opposing many of those tenets which the divines were endeavouring to establish. His learning recommended him to the parliament, whose visitors, having ejected Dr William Spurstow from the mastership of Catharine Hall in Cambridge, put Lightfoot in his room, in the year 1653; and he was also presented to the living of Much-Munden in Hertfordshire, void by the death of Dr Samuel Ward, Margaret-professor of divinity in that university, before the expiration of this year. Meanwhile he had his turn with other favourites in preaching before the House of Commons, most of which sermons were printed; and in them we see him warmly pressing the speedy settlement of the church in the Presbyterian form, which he cordially believed to be according to the pattern in the Gospel. He was all the while employed in preparing and publishing the several branches of his *Harmony*, which were so many excellent specimens of the usefulness of human learning to true religion; but he met with great difficulties and discouragements in that work, chiefly from that spirit of hostility to erudition which then prevailed, and even threatened the destruction of the universities. In 1655 he entered upon the office of vice-chancellor of Cambridge, to which he was chosen that year, having taken the degree of doctor of divinity in 1652. He performed all the regular exercises for his degree with great applause, and executed the vice-chancellor's office with exemplary diligence and fidelity; and, particularly at the commencement, supplied the place of professor of divinity, then undisposed of, as an act which was kept for a doctor's degree in that profession. At the same time he was engaged with others in perfecting the Polyglott Bible, then in the press. At the Restoration he offered to resign the mastership of Catharine Hall. But, as what he had done had been rather in compliance with the necessity of the times than from any zeal or spirit of opposition to the king and government, a confirmation was granted to him by the crown, both of the place and of his living. Soon after this he was appointed one of the assistants at the conference upon the liturgy, which was held in the beginning of 1661, but attended only once or twice; being probably disgusted at the heat with which that conference was managed. However, he stuck close to his design of perfecting his *Harmony;* and being of a strong and healthy constitution, which was assisted by a strict temperance, he prosecuted his studies with unabated vigour to the last, and continued to publish, notwithstanding the many difficulties he met with from the expense of the work. However, not long before he died, some booksellers got a promise from him to collect and methodise his works, in order to print them; but the execution was prevented by his death, which happened on the 6th of December 1675. Dr Lightfoot was twice married; and his first wife brought him four sons and two daughters. His second wife was likewise a widow, relict of Mr Austin Brograve, uncle of Sir Thomas Brograve, of Hertfordshire, a gentleman well versed in rabbinical learning, and a particular acquaintance of our author; but he had no issue by her. She died before him, and was buried in Munden church, where he was himself likewise interred near both his wives. Dr Lightfoot's works were first collected and published in 1684, in two volumes folio. The second edition was printed at Amsterdam, 1686, in two volumes folio, containing all his Latin writings, with a Latin translation of those which he wrote in English. At the end of both these editions there is a list of such pieces as he left unfinished. It is the chief of these, in Latin, which make up the third volume, added to the former two, in a third edition of his works, published by John Leusden, at Utrecht, in 1699, folio. They were communicated by Mr Strype, who, in 1700, published another collection of these papers, under the title of Some Genuine Remains of the late pious and learned Dr John Lightfoot.

Lighting of Streets.

LIGHTING of Streets. This invention, which is generally considered as of modern date, contributes greatly to the convenience and safety of the inhabitants of large cities, as well as to the ornament of their streets. It is not probable that the streets of ancient Rome were lighted, since the Romans considered the use of flambeaux and lanterns as necessary in returning home from their nocturnal visits. It appears that such as walked the streets without these went home in darkness; and the return of Gito in the night time, of which Petronius makes mention, clearly proves that the streets of Naples were not lighted. Those who have ascribed to a remote antiquity the lighting of streets, seem to have mistaken it for illuminations, which indeed were of great antiquity. Egyptians, Jews, Greeks, and Romans, during the celebration of memorable festivals, were in the habit of illuminating their houses; but this is entirely different from the practice which we are now considering.

Paris was probably the first city in modern times, the streets of which were lighted about the beginning of the sixteenth century, as they were much infested by robbers and incendiaries. This occasioned an edict, issued in 1524, commanding the inhabitants, whose windows fronted the street, to keep lights burning after nine o'clock at night. In 1558, these were changed for lanterns, of a similar construction with those used at present. In 1671 the lanterns were ordered to be lighted every year from the 20th October to the end of March the ensuing year. Some time after this a premium was offered for a dissertation on the best means of improving the lighting of the streets, when a journeyman glazier obtained a premium of 200 livres, and MM. Bailly, Le Roy, and Bourgeois de Chateaublanc, 2000 livres. The lamps of Paris amounted in 1721 to 5772, and in 1771 to 6232. The city of Nantes was lighted in 1777, and had no fewer than 500 lamps in the year 1780.

The inhabitants of the city of London were ordered, in 1688, to hang out lanterns duly at the accustomed time, which order was renewed in 1690; and in 1716 it was enacted that all those whose houses fronted any street, lane, or public passage, should hang out one or more lights, which were to burn from six o'clock till eleven. By another act, the lamps were increased from 1000 to 4769, and afterwards to 5000. But as these were confined to the city and liberties, about one fifth of the whole of London, the number of lamps could not be less than 15,000. The continuance of their burning was also increased from 750 to 5000 hours. In 1744, another act was obtained to regulate still farther the lighting of the city, and it was placed on the footing on which it stood until the introduction of gas-light. Birmingham was lighted for the first time in 1733, with 700 lamps.

In 1669 Amsterdam was lighted by lanterns; the Hague in 1553 was lighted in a particular manner, but lamps were not fixed up in all the streets till the year 1678. The streets of Copenhagen were lighted in 1681, and the plan of lighting was much improved in 1683. Vienna began to be lighted in 1687, and lamps were introduced in 1704. In 1776 their number amounted to 2000, which was increased to 3000, to be lighted at the annual expense of 30,000 florins. Leipzig was lighted in 1702, Dresden in 1705, Cassel in 1721, and Göttingen in 1735. A practice so beneficial to the safety and convenience of mankind has been very laudably imitated by almost every city and town in Europe.

By far the greatest improvement that has been made in the lighting of cities is the application of coal-gas to this purpose. See the article GAS-LIGHTS.

LIGHTNING, a bright and vivid flash of fire, suddenly appearing in the atmosphere, and commonly disappearing in an instant, sometimes attended with clouds and thunder, and sometimes not.

Lightning was looked upon as sacred both by the Greeks and Romans, and was supposed to be sent to execute vengeance on the earth. Hence persons killed with lightning, being considered as hateful to the gods, were buried apart by themselves, lest the ashes of other men should receive pollution from them. Some say they were interred upon the very spot where they died; others think that they had no interment, but were suffered to rot where they fell, because it was unlawful for any man to approach the place. For this reason the ground was hedged in, lest any person should unawares contract pollution from it. All places struck with lightning were carefully avoided and fenced round, from an opinion that Jupiter had either taken offence at them, and fixed upon them the marks of his displeasure, or that he had, by this means, pitched upon them as sacred to himself. The ground thus fenced about was called by the Romans *bidental*. Lightning was much observed in augury, and was a good or bad omen, according to the circumstances attending it.

LIGULATED, amongst botanists, is an appellation given to such floscules as have a straight end turned downwards, with three indentures, but not separated into segments.

LIGURIA, in *Ancient Geography*, a country of Italy, bounded upon the south by the Mediterranean Sea, upon the north by the Appenine Mountains, upon the west by part of Transalpine Gaul, and upon the east by Etruria. There is a great disagreement amongst authors concerning the origin of the Ligurians, though most probably they were descended from the Gauls. Some carry back their origin as far as the fabulous heroes of antiquity; whilst others trace them from the Ligyes, a people mentioned by Herodotus as having attended Xerxes in his expeditions against Greece. These Ligyes were by some ancient geographers placed in Colchis, and by others in Albania. According to Diodorus Siculus, the Ligurians led a very wretched life; their country being entirely overgrown with woods, which they were obliged to pull up by the roots, in order to cultivate their land, which was also encumbered with great stones, and, being naturally barren, made but a very poor return for their labour. They were much addicted to hunting; and, by a life of continual exercise and labour, became so strong, that the weakest Ligurian was generally an overmatch for the strongest and most robust amongst the Gauls. The women are said to have been almost as strong as the men, and to have borne an equal share in all laborious enterprises. With all their bravery, however, they were not able to resist the Roman power, but were subdued by that warlike nation about 211 B.C.

LILBURNE, JOHN, an enthusiastic demagogue, who was tyrannically punished by the star-chamber court, being put in the pillory, whipped, fined, and imprisoned, for importing and publishing seditious pamphlets, printed in Holland, and which chiefly reflected on the church of England and its bishops. He suffered imprisonment in 1637, and in jail was doubly loaded with irons. In 1641, he was released by the long parliament; and from this time he had the address to make himself formidable to all parties, by his bold and aspiring genius. He signalized himself in the parliament army; and was at one time the secret friend and confidant of Cromwell, and at another his avowed enemy and accuser; so that, in 1650, Cromwell found it to be his interest to silence him, by a grant of some forfeited estates. But after this he grew outrageous against the protector's government; became the chief of the levellers; and was twice tried for high treason, but acquitted by the juries. The last trial of Lilburne was for returning from exile without a pass, after having been banished by the parliament. He died in 1657, aged eighty-eight.

LILIACEOUS, in *Botany*, an appellation given to such flowers as resemble those of the lily.

LILLO, GEORGE, an excellent dramatic writer, was born at London in 1693. He was a jeweller by profession, and followed his business for many years in that neighbourhood with a fair reputation. He was at the same time strongly attached to the muses, yet seemed to have laid it down as a maxim, that the devotion paid to them ought always to tend to the promotion of virtue, morality, and religion. In pursuance of this aim, Lillo was happy in the choice of his subjects, and showed great power of affecting the heart, by working up the passions to such a height as to render the distresses of common and domestic life equally interesting to the audiences with those of kings and heroes, and the ruin brought on private families by an indulgence of avarice, lust, and other passions, with the havoc made in states and empires by ambition, cruelty, or tyranny. His George Barnwell, Fatal Curiosity, and Arden of Feversham, are all planned on common and well-known stories; yet they have perhaps more frequently drawn tears from audiences than the more pompous tragedies of Alexander the Great, All for Love, and others of the same stamp. In the prologue to Elmeric, which was not acted till after the author's death, it is said, that when he wrote that play, he was depressed by want and afflicted by disease; but in regard to the former particular, there appears to be evidently a mistake, as he died possessed of an estate of L.60 a year, besides other effects to a considerable amount. His death happened in 1739, in the forty-seventh year of his age. His works have been collected and published, with an account of his life, in two vols. 12mo.

LILLY, JOHN, a dramatic poet, was born in the Wealds of Kent, about the year 1553, and educated in Magdalen College, Oxford, where he took the degree of bachelor of arts in 1573, and that of master in 1575. From Oxford he removed to Cambridge; but how long he continued there is uncertain. On his arrival in London, he became acquainted with some of Queen Elizabeth's courtiers, by whom he was caressed and admired as a poet and a wit; and her majesty, on particular festivals, honoured his dramatic pieces with her presence. His plays are nine in number. His first publication, however, printed in 1580, was a romance called *Euphues*, which was universally read and admired. This romance, which Blount, the editor of six of his plays, says, introduced a new language, especially amongst the ladies, is, according to Berkenhout, in fact a most contemptible piece of affectation and nonsense. Nevertheless it is very certain, that it was in high estimation amongst the women of fashion of those times, who, we are told by Whalley, the editor of Ben Jonson's works, had all the phrases by heart; and those who did not speak *Euphuism* were as little regarded at court as if they could not speak French. "He was," says Oldys, "a man of great reading, good memory, ready faculty of application, and uncommon eloquence; but he ran into a vast excess of allusion." When or where he died is not known. Anthony Wood says he was living in 1597, when his last comedy was published. After attending the court of Queen Elizabeth for thirteen years, notwithstanding his reputation as an author, he was under the necessity of petitioning the queen for some small stipend to support him in his old age. His two letters or petitions to her majesty on this subject are preserved in manuscript.

LILLY, *William*, a noted English astrologer, was born in 1602 in Leicestershire, where his father not being able to give him more learning than common writing and arithmetic, he resolved to seek his fortune in London. He arrived in 1620, and lived four years as a servant to a mantua-maker in the parish of St Clement Danes; but he then moved a step higher to the service of Mr Wright, master of the Salters' Company in the Strand; and as he was not able to write, Lilly, amongst other offices, kept his books. In 1627, when his master died, he paid his addresses to the widow, whom he married with a fortune of L.1000. Being now his own master, he followed the puritanical preachers; and turning his mind to judicial astrology, became the pupil of one Evans, a profligate Welsh parson, in that pretended art. Getting a manuscript of the *Ars Notitiæ* of Cornelius Agrippa, with alterations, he drank in the doctrine of the magic circle, and the invocation of spirits, with great eagerness. He was the author of the *Merlinus Anglicus junior*, the Supernatural Sight, and the White King's Prophecy. In him we have an instance of the general superstition and ignorance that prevailed in the time of the civil war between Charles I. and his parliament; for the king consulted this astrologer to know in what quarter he should conceal himself, if he could escape from Hampton Court; and General Fairfax, on the other side, sent for him to his army, to ask him if he could tell by his art, whether God was with them and their cause. Lilly, who made his fortune by favourable predictions to both parties, assured the general that God would be with him and his army. In 1648, he published his treatise of the Three Suns seen the preceding winter; and also an astrological judgment upon a conjunction of Saturn and Mars. This year the council of state gave him in money L.50, and a pension of L.100 per annum, which he received for two years, and then resigned on some disgust. In June 1660, he was taken into custody by order of the parliament, by whom he was examined concerning the person who had cut off the head of King Charles I. The same year he sued out his pardon under the great seal of England. When the plague raged in London, he removed with his family to his estate at Hersham; and in October 1666, he was examined before a Committee of the House of Commons concerning the fire of London, which happened in September that year. After his retirement to Hersham, he applied himself to the study of physic, and, by means of his friend Mr Ashmole, obtained from Archibald Sheldon a license for the practice of it. A little before his death he adopted for his son, by the name of Merlin the Younger, one Henry Coley, a tailor by trade; and at the same time gave him the impression of his almanack, after it had been printed for thirty-six years. He died in 1681 of a dead palsy. Mr Ashmole placed a monument over his grave in the church of Walton-upon-Thames. His Observations on the Life and Death of Charles, late king of England, if we overlook the astrological nonsense, may be read with as much satisfaction as more celebrated histories; Lilly being not only very well informed, but strictly impartial. This work, with the Lives of Lilly and Ashmole, written by themselves, were published in one volume 8vo, in 1774, by Mr Burman.

LILYBÆUM, in *Ancient Geography*, a city of Sicily, situated on the most westerly promontory of the island, and said to have been founded by the Carthaginians on their expulsion from Motya by Dionysius, tyrant of Syracuse. It is remarkable for the three sieges it sustained; one by Dionysius the tyrant, another by Pyrrhus, king of Epirus, and the third by the Romans. The first two failed in their attempts, but the Romans with great difficulty made themselves masters of it. No remains of this once stately city are now to be seen, except some aqueducts and temples.

LILYE, WILLIAM, a grammarian, was born in the year 1466 at Oldham in Hampshire, and in 1486 admitted a semi-commoner of Magdalen College, Oxford. Having taken the degree of bachelor of arts, he left the university, and travelled to Jerusalem. Returning thence, he continued five years in the island of Rhodes, where he studied the Greek language, several learned men having retired thither after the taking of Constantinople. From Rhodes he travelled to Rome, where he improved himself in the Greek and Latin languages, under Sulpitius and Sabinus. He then returned to London, where for some time he taught a private grammar-school, being the first person who taught Greek in the metropolis. When Dr Colet founded St Paul's school, 1510, Lilye was appointed the first master; at which time, it seems, he was married, and had many children. In this employment he had laboured twelve years, when, being seized by the plague, which then raged in London, he died in February 1523, and was buried in the north yard of St Paul's. He had the character of an excellent grammarian, and a successful teacher of the learned languages. His principal work is *Brevissima Institutio, seu ratio Grammatices cognoscendæ*, London, 1513, reprinted times without number, and commonly called Lilye's Grammar. The English rudiments were written by Dr Colet, Dean of St Paul's; and the preface to the first edition, by Cardinal Wolsey. The English syntax was written by Lilye, and also the rules for the genders of nouns, beginning with *propria quæ maribus*, and those for the preterperfect tenses and supines, beginning with *As in presenti*. The Latin syntax was chiefly the work of Erasmus. (See Ward's preface to his edition of Lilye's Grammar, 1732.)

LIMA, a department of the republic of Peru, in South America, bounded on the north by Truxillo, on the east by Junin and Ayacucho, on the south by Arequipa, and on the west by the Pacific Ocean. The Cordillera of the Andes ranges along its eastern side. The climate is considered as fine; and although the atmosphere is cloudy and humid, it seldom rains throughout the whole year. The heat is excessive along the coast; but as the country becomes more elevated towards the interior, the air becomes purer and more temperate. Earthquakes are frequent, from six to twelve occurring annually; and these convulsions of nature on a large scale seem to observe a periodical return at intervals of fifty years. It is watered by several streams, but none of any considerable size, the largest being the river Rimac, which, during the summer months, is much swollen by torrents from the Andes. The soil is good, and agricultural pursuits are followed to a considerable extent. The chief wealth of the country, however, consists in the produce of the mines, which are worked by proprietors in Lima. Next to Lima in importance is the sea-port of Callao, situated in the bay of that name, and containing a population of about 8000. The port is defended by three castles, which are surrounded with thick walls, a moat, and batteries of great strength. It is connected with the city of Lima by a straight road, about six miles in length. It was entirely destroyed by an earthquake in 1746, when upwards of 3000 of the inhabitants are said to have perished, and nineteen ships sunk in the harbour. Trade has lately much increased, and the town has greatly improved. Its appearance, however, is mean and unfavourable.

LIMA, a city in the department of that name, and capital of the republic of Peru, is situated in a spacious plain, on the southern bank of the river Rimac, about ten miles from the sea. Long. 76. 56. 45. W. Lat. 12. 3. S. The population, according to the latest accounts, is 40,000 inhabitants. It was founded in 1553 by Pizarro, who called it La Ciudad de les Reyes, or City of Kings; but the name has been since changed to Lima, a corruption of Rimac. The city is built in an amphitheatre formed by sierras of the great chain of the Andes, which shelter it from the northerly and easterly winds. The figure of the city is nearly semicircular, the river being the diameter, and is two miles long from east to west, and one and a quarter in breadth. It consists of 157 squares, and 355 streets, built at right angles, and about twenty-five feet wide. The streets are well paved, and furnished with streams of water, which are arched over, and rendered subservient to cleanliness and other conveniences. It stands nearly 700 feet above the level of the sea, and, when seen from Callao roads, presents a beautiful appearance, owing to its numerous domes and spires rising from so elevated a situation. The entrance is by a fine avenue or public walk called the Almeda, at the termination of which are the ruins of a handsome gate. It is surrounded by a brick wall, flanked with thirty-four bastions, but without embrasures. At the south-eastern extremity of the city is a small citadel, called Santa Catalina; and on the right side of the river, connected with the city by a bridge, is the suburb of San Lazarro, which is inhabited by the lower classes. The city having suffered much from earthquakes, the houses are generally built of one story, the walls being composed of mud and cut straw, formed into bricks by the heat of the sun, and strengthened by pieces of timber. The houses of the wealthy inhabitants, built in a Moorish style, generally consist of a square pile, two stories in height, enclosing a quadrangular court, which is surrounded with piazzas, and sometimes contains a second, or even third inner court. The Plaza, or great square, in the centre of the city, is surrounded partly with shops and private houses, and partly with public buildings. On the eastern side is the cathedral, to the north of which is the principal parish church, adorned with a beautiful façade, and adjoining it is the archiepiscopal palace, part of which is now occupied by the Peruvian synod. On the north side are the viceroy's palace and the city hall, under which is the city jail. In the centre of the square is a fine brass fountain, erected in 1653, the water of which being the best in Lima, is conveyed to all parts of the city. In this square the principal market is held. The cathedral is a noble edifice, and at each corner is a tower, nearly 200 feet in height. The interior is very rich, and the high altar has a magnificent appearance. The roofs of the houses, and domes and spires of the churches, are built of wood, covered with stucco-work, variously ornamented, which presents a splendid appearance when viewed from a distance; but the traveller is apt to feel disappointed upon a nearer inspection. Formerly the number of monks was reckoned at 1200, but they have now decreased nearly one fifth in amount. There are fourteen convents for females, and a number of religious houses, into which ladies retire for a short period. Some of the conventual churches are remarkably beautiful; that of St Domingo having a tower about 180 feet high, which is the loftiest in the city. There are several hospitals of a charitable and benevolent description. The university, founded in 1549, and possessing peculiar privileges, is a handsome building, with several good halls, and an extensive library.

The higher classes of the inhabitants are generally well educated, though in a limited sense; and the females are equally celebrated for their vivacity and beauty. They are said, however, to be somewhat licentious in their manners; and their walking-dress, consisting of a petticoat fitted close to the body, and a hood thrown over the head, seems peculiarly favourable to intrigue. Both sexes are addicted to smoking; but the females do not practise it openly. All classes of the inhabitants are extravagant in their dress, the richest stuffs of Europe being used even on ordinary occasions. Music, cards, and dancing, are the principal sources of amusement; bull-fights having been abolished. Gambling formerly prevailed in the higher circles; but this vice has of late sensibly diminished. The Spaniards of Lima are at present almost all creoles; the European Spaniards having quitted the country at the period of the revolution. There were formerly 15,000 slaves; but slavery was abolished in 1828 by the new constitution. Lima has been repeatedly laid in ruins by earthquakes, the most destructive of which were those of 1678 and 1746, when, out of 3000 houses, not more than twenty were left standing. In 1822 and 1828 also very destructive earthquakes occurred. The political events which have occurred in Lima will be fully detailed under the article Peru.

LIMASSOL, or Limisso, a town of Cyprus, in the south of the island. Of the ancient city, nothing but ruins now remain, though it was a celebrated place, even under the government of the dukes. King Richard, the conqueror of the last of these vassals of the empire, razed it in 1191, and it was never afterwards rebuilt. This city was originally the same as Amathus or Amathonte, so famous for its temple erected in honour of Venus and Adonis. Amathus was the residence of the first nine kings of the island, and amongst others of Onelistus, who was afterwards subdued by the arms of Artabanes, the Persian general. This city, erected into an archbishopric in the time of the Christians, has produced a number of personages celebrated for their knowledge and the sanctity of their lives. Richard, king of England, having destroyed Amathonte, Guy de Lusignan, in the twelfth century, laid the foundation of the new city which the Greeks called *Neopoleos*. The family of Lusignan, who continued to embellish and fortify it, built there palaces, besides Greek and Latin churches, and made it the seat of a bishop. When the island was taken by the Turks in 1570, the Ottoman army entered this city on the 2d of July, and ravaged it without mercy. It was then destroyed by fire.

LIMB, in general, denotes the border or edge of a thing. Thus we say, the limb of a quadrant, of the sun, of a leaf, and so forth.

Limb, in *Anatomy*, an appellation given to the extremities of the body, as to the arms and legs.

Limb, *Limbus*, *Limbo*, in the church of Rome, is used in two different senses. The limbo of the patriarchs is said to be the place where the patriarchs waited the redemption of mankind, and where they suppose our Saviour's soul continued from the time of his death till that of his resurrection. The limbs of infants dying without baptism, is a place supposed to be distinct from both heaven and hell; since they hold that children dying innocent of any actual sin, do not deserve hell, and, by reason of their original sin, cannot be admitted into heaven.

LIMBAT, the name of a periodical wind, common in the island of Cyprus, and of great service in moderating the heats of the climate, which would otherwise be intolerable.

LIMBORCH, Philip, a learned writer amongst the Remonstrants, was born at Amsterdam in 1633. After having made great proficiency in his studies, he was, in 1655, admitted to preach in public, which he did first at Haerlem. His sermons had in them no affected eloquence, but were solid, methodical, and edifying. He was chosen minister of Gouda, whence he was called to Amsterdam, where he held the professorship of divinity, in which he acquitted himself with great reputation till his death, which happened in 1712. He had many friends of distinction in foreign parts, as well as in his own country. Some of his letters to Mr Locke are printed along with those of that celebrated author. He had all the qualifications suitable to the character of a sincere divine, lived an example of every virtue, and preserved the vigour of his body and mind till a considerably advanced age. He wrote many estimable works, the principal of which are, 1. *Amica Collatio de veritate religionis Christianæ cum erudito Judæo*, in 12mo; 2.

a Complete Body of Divinity, according to the opinions and doctrines of the Remonstrants; and, 3. a History of the Inquisition, which was translated into English by Dr Samuel Chandler. Limborch also published the works of the famous Episcopius, who was his great-uncle by the mother's side.

LIMBURG, a city of the Netherlands, in the province of Liège, and arrondissement of Verviers. It is fortified, and stands on the river Besdre, and, including its suburb Dalhem, contains 320 houses, and 2000 inhabitants. Long. 5. 58. E. Lat. 50. 40. N.

LIMBURG, a city of the duchy of Nassau, in Germany, the capital of the bailiwick of that name. It is situated on the river Lahn, is surrounded with walls, and has the mint for the ducal coinage. It has some mineral springs, and contains 508 houses, with 2820 inhabitants. The neighbourhood produces the best wheat of any part of Germany.

LIMBURG, a province of the Netherlands, formed out of the greater part of the former French department of the Lower Meuse, and a small portion of the department of the Roer, to which has been added a portion of Dutch Limburg, part of the bishoprick of Liège, of Austrian and Prussian Guelders, and some small part of the duchies of Cleves and Juliers, with communes taken from the circle of Westphalia in Germany. It is now a compact district, extending over 1546 square miles, between north latitude 50. 44. and 51. 45. and between east longitude 4. 52. and 6. 5. It is a level plain, except that a few hills, of no great height, rise in the south-east division. The soil is generally fertile in the vale, through which the Meuse, its only navigable river, runs; but the north-western part consists chiefly of barren heaths. The parts of these heaths that are cultivated produce scarcely any grain, except buck wheat. The meadows on the banks of the Meuse, as well as the lands adjoining to them, where clover is grown, are adapted to the breeding and fattening of cattle; and their dairies, which are conducted on the plan of the Hollanders, produce excellent butter and cheese. Much rape seed is also raised for making oil, and the crops of hemp, flax, madder, chicory, and tobacco, are found profitable. Coals are obtained in some parts; and the quarries yield good stone, peculiarly adapted to building under water, for which there is a great demand in Holland. The manufactures of the province are inconsiderable, and confined chiefly to such articles as are of common domestic demand. There are in the province three arrondissements, divided into twenty-two cantons, and subdivided into 336 communes. The inhabitants, amounting to 292,500, are for the most part of the Walloon race; but the Dutch, Flemish, and Walloon dialects are almost equally spoken by them. The capital is Maestricht.

LIMERICK, a maritime county of the province of Munster, in Ireland, is bounded on the north by the estuary of the Shannon and the county of Tipperary, on the east by the same county, on the south by the county of Cork, and on the west by that of Kerry. In extent of surface it ranks as tenth amongst the counties of Ireland. It contains 674,783 acres, of which 582,802 acres are fit for cultivation, and only 91,981 are bog or unprofitable mountain.

It was formerly inhabited by the tribe of the Velaborii. The principal Irish families in it afterwards were the O'Briens, O'Gradys, O'Gormans, M‘Enerys, M‘Sheehys, Moronys, M‘Mahons, and O'Quins. Much of it was confiscated in the time of Cromwell, since which period the proprietorship of the soil has mostly devolved upon settlers of English descent. The county is now divided into the ten baronies of Clanwilliam, Upper and Lower Conello, Coonagh, Coshma, Costlea, Kenry, Owneybeg, Pubblebrian, and Small County, which are again subdivided into 126 parishes.

According to the ecclesiastical arrangements of the country, the county of Limerick comprehends portions of the dioceses of Limerick, Emly, Killaloe, and Cashel. The whole of the first named of these dioceses, a small portion excepted, is within the county; eighty-five of the parishes which constitute it being within its limits, and three only in the county of Clare. This see is one of the few which is unaffected by the changes introduced into the ecclesiastical divisions of Ireland by the late consolidation of the bishoprics. It is still, as before, to continue united with those of Ardfert and Aghadoe in Kerry. Its revenue is estimated at L.5369 per annum. The cathedral, an ancient and venerable pile, stands in the city of Limerick; and the bishop's palace, a modern mansion, is situated on the bank of the Shannon, at the western extremity of the city. The chapter consists of a dean, precentor, chancellor, treasurer, and archdeacon, and has eleven prebendaries and six vicars-choral connected with it. The see of Emly, united with that of Cashel, has thirty-eight parishes in the county of Limerick, and twenty in that of Tipperary. The seat of the see is in the latter county. One parish of the diocese of Cashel, and two of that of Killaloe, are within the limits of the county of Limerick.

The face of the country, though diversified by numerous small hills, is not mountainous, except on the south-east, where it is bounded by the Galtees, a ridge of considerable extent, and 2500 feet high at its most elevated point, extending into the adjoining county of Tipperary. On the borders of Kerry the surface also rises into a grand amphitheatre of low but steep mountains, that spread themselves out in a wide curve from Loghill to Drumcollogh. The only river of any size is the Maig, which rises in the Galtees, and discharges itself into the Shannon west of Limerick. It is navigable by barges as far as the town of Adare. A plan to make this river available for the purpose of connecting the cities of Limerick and Cork, by an inland navigation from Adare to Mallow on the Blackwater, has not been carried into effect. The Feale and the Gale, which rise in the western mountain range, are considered as belonging to Kerry, and the Blackwater, which rises in the same range, to Cork. The county is well watered by numerous smaller streams. Its only lake is Lough Gur, about five miles in circumference, and studded with several small islands.

The soil in the level parts is considered as the richest in Ireland. The Golden Vale, a district which obtained its name from the remarkable exuberance of its fertility, lies mostly in this county. Along the banks of the Shannon are large tracts of marsh land, called corcachs, also celebrated for their richness; a circumstance attributed to the quantity of alluvial mould deposited there by the Shannon when it overflows its banks. In a geological point of view the low country forms part of the great flœtz limestone plain of Ireland; but the mountainous district in the south and west consists chiefly of sandstone. A mine of coal or culm is worked at Loghill, but it is found to be better adapted for kilns than for domestic use. At Castleconnel, a town beautifully situated, is a mineral spa of great celebrity from its sanative effects. It is of the same quality as the Poutron at Spa.

The state of the population, at the different periods at which returns respecting it have been made, together with the authorities on which those returns depend, is as follows:—

1760	De Burgho	92,376
1792	Beaufort	170,000
1821	Parliamentary return	218,432
1832	Ditto	233,505

The returns from the commissioners of public instruction in 1834, being made in dioceses instead of counties, cannot be rendered available in this and the subsequent statement. The return of 1831 gives an average of one inhabitant to every two acres and eighty-eight hundred parts of the county in general, and to every two acres and thirty-five hundred parts of that portion of its land which is capable of profitable cultivation.

The state of education in 1821 and 1824–26 was as follows:—

Year.	Boys.	Girls.	Sex not ascertained.	Total.
1821,	16,510	7,896	—	24,406
1824–26,	19,173	10,347	568	30,088

Of the numbers in the latter of these statements, 2064 were Protestants of the established church, 27,735 were Roman Catholics, and 45 were dissenters; but the religious persuasion of 244 was not ascertained. The total number of schools was 461; of which 27, affording education to 2841 children, were maintained by grants of public money; 29, educating 3274 children, were supported by the voluntary contributions of societies or individuals, and the remaining 405 schools, in which 24,040 children were educated, depended wholly on the fees of the pupils.

The county returned eight members to the Irish parliament; two for the county at large, two for the city of Limerick, and two for each of the boroughs of Askeaton and Kilmallock. The boroughs having been disfranchised at the union, the number of representatives sent to the imperial parliament was fixed at three, two for the county and one for the city. The reform act has added one representative to the latter place.

The land in the level parts is divided into large farms, many of which are almost exclusively devoted to grazing. In the more hilly region the farms are smaller, and in some parts cut up into holdings much too small for the profitable culture of the soil, or the comfortable support of the cultivators. Still, however, the agricultural produce is considerable. Wheat, barley, oats, and rape, are raised in large quantities. In the year 1709, a colony of Palatines brought from Germany by Lord Southwell settled near Bruff, Rathkeale, and Adare. They tended much to improve the state of agriculture, as also that of the linen manufacture. The rich lands on the borders of the rivers produce a kind of flax very different from that of the north; it grows to a great height, and is well adapted for sail-cloth. Hemp was formerly cultivated extensively on the lands of the same quality. The horses are of large size, strong, active, and generally well bred; the heaviest and fattest beasts slaughtered in the southern markets are reared in this county. The sheep are also of a good description, but they are not bred here. Hogs of large size are sent to the same markets. The exportation of cattle and grain is very considerable, constituting the main source of the wealth of the inhabitants. The Shannon, which here assumes the character rather of an estuary of the ocean than of an inland river, supplies marine fish, both round and flat, in great abundance. Pike, carp, tench, trout of large size, and salmon highly esteemed for its flavour, are caught in most of the rivers.

The manners of the people are similar to those in other parts of the province. Their habits are almost exclusively agricultural. Their dwellings are poor, their food chiefly the potato; their fuel is turf, except near the collieries at Loghill, and in the immediate neighbourhood of the city, where British coal is much used. The Irish language is still spoken by the peasantry in their colloquial intercourse, but the English is universally understood and spoken, excepting perhaps in some of the more retired mountain districts.

The county possesses many remains of antiquity. The most remarkable of the ancient monastic buildings are in the city of Limerick, where, besides the cathedral, there was a Dominican friary founded by Carbreagh O'Brien, king of Thomond, in which he was interred. Some remains of the monument erected to his memory still exist. In the same city was an Augustinian friary, a convent of black nuns, a Franciscan friary, and a preceptory of knights-templars, besides several other minor religious establishments. Amongst the most admired of the many fine monastic ruins in various parts of the county is the the abbey of Adare.

The city of Limerick, the capital of the county, is situated on the Shannon, about 100 miles from its mouth, partly on an island and partly on the main land. It is the third city in Ireland in population and importance, being surpassed in these respects only by Dublin and Cork. The number of its inhabitants in 1821 and 1831 was 59,045 and 66,575 respectively. The city consists of three principal divisions; the Irish town, the English town, and Newtown Pery. The first is the most ancient, having been built before the arrival of the English in 1172. The second occupies King's Island, on the Shannon, and was formerly a strongly fortified position. The third was commenced in 1769, by Mr Sexton Pery, from whom it takes its name. It is laid out along the eastern banks of the river, in streets, intersecting each other at right angles with the utmost geometrical precision. The city was formerly considered as the strongest place in Ireland. In 1174 it was taken by the English, but shortly afterwards evacuated by them, and burned, to prevent its occupation being serviceable to the enemy. In 1651 it was taken by Ireton, Cromwell's lieutenant-general, after a vigorous resistance; and in 1690, its garrison baffled the army of King William, who conducted the siege in person; but it surrendered on terms the next year to General Ginckel, on which occasion the celebrated treaty of Limerick was concluded. Most of the walls and gates have been demolished, and quays, warehouses, and streets built on their site. The different parts of the town are connected with each other by bridges, of which Thomond Bridge is worthy of notice from its antiquity, and Wellesley Bridge, lately erected, still more so, as being one of the finest specimens of this kind of architecture in the island. Besides the cathedral, and three parish churches, and two chapels of ease of the established church, there are seven Roman Catholic places of worship. The methodists, presbyterians, baptists, independents, and quakers, have each a meeting-house. The court-house is a handsome building. The prison is constructed according to the modern improvements in prison discipline. The other more remarkable public buildings are the Tholsel, which is ornamented with a Tuscan colonnade, the custom-house, the commercial buildings, and the lunatic asylum. The city was originally incorporated by King John, whose charter was confirmed and extended by several succeeding sovereigns. It was first governed by a bailiff, but obtained the privilege of electing mayors and sheriffs ten years before that right was conferred on London. The city officers at present are, the mayor, two sheriffs, a recorder, four charter justices, to which the lord chancellor is empowered to add six more, and a common council, whose number fluctuates from thirty-seven to forty. This body is self-elective. It has also a military governor, constable, and town-major, and is a permanent military station. The jurisdiction of the city extends over a considerable space, the city and liberties comprehending twenty-one parishes or parts of parishes. One of the principal public institutions is the Chamber of Commerce, incorporated by charter and act of parliament. It is possessed of considerable property, a savings bank, and a mechanics' institute consisting of about 200 members. The charitable endowments are numerous, and some of them extensive. They are, the house of industry, which supports an average number of 336; the lunatic asylum, fever hospital, lying-in hospital, Magdalen asylum, dispensary, Barrington's hospital, Villars's alms-house, asylum for the blind, Hall's alms-houses, the forty-shillings alms-houses, Craven's charity, Mrs Rose's charity, and the jubilee, Pery, and London tavern loan funds. The trade of this place is extensive, and various linen, woollen, cotton, and paper manufactures are carried on in it. Several breweries, distilleries, and salt-works, find permanent employment. The exports chiefly consist of provisions and grain. The imports are, coal, turf, for the carrying of which from Clare and Kerry, 200 barges of twenty tons each are employed; timber, wine, spirits, and all the articles of British and foreign production which the wants or luxuries of a numerous and well-employed population require. Vessels of 400 tons' burden ride at the quay. The navigation from the Atlantic to the city is open and secure, and the inland navigation connects it with Dublin, and all the intermediate line of country. The estimated value of the exports and imports for 1832 was, exports L.1,005,727, imports L.289,596. Large quantities of merchandise are brought by the Grand Canal from Dublin.

The number of vessels that have cleared outwards from the port during a period of five years is as follows:

Year.	Vessels.	Tonnage.
1828	462	58,242
1829	334	42,591
1830	365	49,513
1831	423	52,316
1832	472	59,004

Eleven vessels, of about 1760 tons in all, belonged to Limerick ship owners in 1832.

The other towns of some note in the county are, Rathkeale, Shanagolden, Ballingarry, Newcastle, Adare, Askeyton, and Castleconnel. Kilmallock is more remarkable for its remaining vestiges of former greatness than for its present condition. It was the second town in the county, having a charter of incorporation, being surrounded by substantial fortifications, and consisting of a number of large houses, so durably constructed of cut stone, that their ruins have induced some modern topographers to distinguish the place, somewhat quaintly, by the title of the Irish Balbec.

Limerick is also the name of a fair-town in the county of Wexford and province of Leinster; the fairs are four in the year.

LIMIT, in a restricted sense, is used by mathematicians for a determined quantity to which a variable one continually approaches; in which sense, the circle may be said to be the limit of its circumscribed and inscribed polygons. In *Algebra*, the term *limit* is applied to two quantities, one of which is greater and the other less than another quantity; and in this sense it is used in speaking of the limits of equations, by which their solution is much facilitated.

LIMITED Problem denotes a problem that has but one solution, or some determinate number of solutions; as to describe a circle through three given points that do not lie in a right line, which is limited to one solution only; to divide a parallelogram into two equal parts by a line parallel to one side, which admits of two solutions, according as the line is parallel to the length or breadth of the parallelogram; or to divide a triangle in any ratio by a line parallel to one side, which is limited to three solutions, as the line may be parallel to any of the three sides.

LIMNING, the art of painting in water-colours, in contradistinction to painting executed in oil-colours.

Limning is by much the more ancient kind of painting. Till a Flemish painter, John van Eyck, better known by the name of *John of Bruges*, found out the art of painting in oil, the painters all painted in water and in fresco, both on walls, on wooden boards, and on other materials. When they made use of boards, they usually glued a fine linen cloth over them, to prevent their opening, then laid on a ground of white, and lastly mixed up their colours with water and size, or with water and yolks of eggs, well beaten with the branches of a fig tree, the juice of which thus mixed with the eggs; and with this mixture they painted their pieces.

In limning, all colours are proper enough, excepting the white made of lime, which is only used in fresco. The azure and ultramarine must be mixed with size or gum; but there are always applied two layers of hot size before the size colours are laid on. The colours are all ground in water, each by itself; and, as they are required in working, are diluted with size-water. When the piece is finished, they go over it with the white of an egg well beaten; and then with varnish if required.

LIMOGES, an arrondissement in the department of the Upper Vienne, in France, 769 square miles in extent. It comprehends nine cantons, divided into eighty-three communes, containing 89,500 inhabitants. The capital of the department, as well as that of the arrondissement, is the city of the same name, situated on the right bank of the river Vienne. It is ill built, with narrow and crooked streets, and very antique buildings. There is a fine Gothic cathedral, the façade of which is much admired. The episcopal palace and the mint are striking edifices. It contains 2570 houses, with 20,500 inhabitants. It is a place of great manufacturing industry, producing cotton twist, thin woollen and some linen goods; china-ware, scarcely excelled by that of Sevres; besides hats, wine, and copper articles. Long. 1. 10. E. Lat. 45. 49. N.

LIMOUX, an arrondissement of the department of the Aude, in France, 762 square miles in extent. It comprehends eight cantons, divided into 151 communes, and is inhabited by 71,800 persons. The capital is a city of the same name, situated in a district abounding in good wine, on the river Aude. It contains 1050 houses, and 6200 inhabitants, who make some of the finer descriptions of cloths, and convert to various purposes most of the iron that is found within the department. Long. 2. 11. E. Lat. 43. 5. N.

LINACRE, Thomas, a physician, was born at Canterbury about the year 1460, and educated there under the learned William Selling. He thence removed to Oxford, and in 1484 was chosen fellow of All-Souls' College. Selling, his former instructor, being at this time appointed ambassador from King Henry VII. to the court of Rome, Mr Linacre accompanied him to Italy, where he attained a high degree of perfection in the Greek and Latin languages. At Rome he applied himself particularly to the study of Aristotle and Galen, in the original. On his return to Oxford, he was incorporated doctor of physic, and chosen public professor in that faculty. But he had not been long in England before he was commanded by Henry VII. to repair to court, to attend the young Prince Arthur as his tutor and physician. He was afterwards appointed physician to the king, and after his death to his successor Henry VIII. Dr Linacre founded two medical lectures at Oxford, and one at Cambridge; but that which has most effectually immortalized his name amongst the faculty, is his being the founder of the College of Physicians in London. He beheld with vexation the wretched state of physic in those times; and, by an application to Cardinal Wolsey, obtained a patent in 1518, by which the physicians of London were incorporated. The intention of this corporation was to prevent illiterate and ignorant persons from practising the art of healing. Dr Linacre was the first president, and held the office as long as he lived. Their meetings were held in his own house in Knightrider Street, which he bequeathed to the college. But, when he was about the age of fifty, he took it into his head to study divinity, entered into orders, and, in 1509, was collated to the rectory of Mersham. In the same year he was installed as prebendary of Wells, in 1518 as prebendary of York, and in the following year was admitted precentor of that cathedral. This, we are told, he resigned for other preferments. He died of stone in the bladder in October 1524, at the age of sixty-four, and was buried in St Paul's. Thirty-three years after his death, Dr John Caius caused a monument to be erected to his memory, with a Latin inscription, which contains the outlines of his life and character. He was a man of great natural sagacity, a skilful physician, a profound grammarian, and one of the best Greek and Latin scholars of his time. Erasmus, in his epistles, speaks highly of his translations from Galen, preferring them even to the original Greek. His works are, 1. *De emendata Structura Latini Sermonis libri sex*, London, printed by Pynson, 1524, 8vo, and by Stephens, 1527, 1532; 2. Rudiments of Grammar, for the use of the Princess Mary, printed by Pynson, and translated into Latin by Buchanan, Paris, 1536. He likewise translated into Latin several of Galen's works, which were at different times printed abroad; also *Procli Diadachi Sphæra*, translated from the Greek, Venice, 1499, 1500.

LINCOLN, a city, the capital of the county of that name, 133 miles from London, situated at the bottom, on the side, and the top of a lofty hill, which rises from the banks of the river Wilham. It was formerly walled, and the castle, now converted into the county prison, still remains. The cathedral is on the summit of the hill, and is a most conspicuous object from an extensive surrounding country. It is a magnificent fabric, with two towers at the western front. It was found to be one of the richest in gold, silver, and precious stones, of any of the religious institutions of the kingdom in the reign of Henry VIII. and is still the seat of the largest of all the bishoprics. The city as a whole is not well built, and the streets leading from the lower to the upper town are too steep to be ascended by carriages, which make use of a circular road round the face of the hill, without the city. The town is governed by a mayor, twelve aldermen, and two sheriffs, and returns, as before, two members to parliament. The assizes and elections for the county are held here. It has no manufactures; and not much trade, what little there is, is carried on by the river Wilham, which has a communication with the Trent, through the Foss Dyke. The city has an exempted jurisdiction, within a circuit of nearly twenty miles. It contains, besides the cathedral, ten parish churches, and seventeen parishes. The inhabitants amounted in 1801 to 4909, in 1811 to 8861, in 1821 to 10,367, and in 1831 to 11,892.

LINCOLNSHIRE, an English maritime county. It is bounded on the north by Yorkshire, on the east by the German Ocean and Norfolk, on the south by Cambridge, Northampton, and Rutland shires, and on the west by Nottinghamshire and Leicestershire. Its greatest length is seventy-three miles, and its greatest breadth forty-eight. The area is 2814 square miles, or about 1,800,000 acres.

The county is divided into three districts or provinces. The largest of these, Lindsey, is more extensive than the other two, containing more than 1,000,000 acres, and stretching from the shores of the German Ocean to Nottinghamshire. It is rather an elevated tract of country, but the whole is so level as scarcely to contain a single hill. The north-eastern part of this division is a very extensive district of heathy land, generally very poor, especially the northern part of it, and denominated the Wolds. Though some parts of it have recently been brought into cultivation, yet a great portion has scarcely any other live stock than the numerous rabbits, which multiply in extended warrens. A small part, however, of this division, contains a rich tract of low land, formed by the rivers Trent, Dun, and Idle, where horned cattle are pastured, and some excellent flax is produced. The province of Lindsey is subdivided into fifteen hundreds and two sokes.

The province of Kesteven extends along the western side of the county, from its middle to its southern extremity; in which latter part is a portion of the fens. Notwithstanding there are many extensive heaths, especially near Lincoln and Ancaster; and though the soil and elevation are various, yet on the whole it may properly be described as a fertile country. Towards the west a ridge of hills, which forms an abrupt boundary, extends from Grantham nearly to Lincoln; but none of the points attains a great elevation. This province is subdivided into nine hundreds and three sokes.

The third province, Holland, contains the greater part of that unhealthy division of Lincolnshire usually called the *Fens*. It is subdivided into three hundreds, sometimes denominated sokes, sometimes wapentakes. The character of this province is similar to that of the province of the same name in the Netherlands, after which it has been called. Nearly the whole of it appears, at a remote period, to have been covered by the sea, and only brought into its present state of productiveness by the active and persevering labour of the inhabitants. The embankments and the draining have been expensive, perpetual, and progressive, and the soil that has been redeemed has conferred a most abundant remuneration. Excellent pasture land has been formed out of the swamps and bogs, and some of it produces extraordinary crops of corn, especially oats. Even in those parts that have not been reclaimed, the reeds, which abound, are converted into good covering for houses and barns, and they are well stocked with aquatic wild fowl. The taking of them is a profitable employment to many persons, and the markets of London are principally supplied from thence with those delicacies. The decoys in this district are more numerous than in any other part of England. They are commonly formed around quiet pools, to which pipes made of bent willows, and covered with nets, gradually enlarging as they approach the water, are conducted. Into the large orifice of the pipes the wild birds are enticed by tame ones trained for that business, and who conduct them into the funnel, when the appearance of a man or his dog behind drives them to the most contracted part, where they are taken. The quantity of birds taken in some seasons is prodigious, amounting to some hundreds of thousands. They usually consist of teal, widgeon, and wild ducks; but occasionally wild geese, godwits, coots, ruffs, and reeves and whimbrels, are caught. In these otherwise unproductive fens, the keeping of geese, principally for the sake of the feathers, is a considerable branch of rural industry, and supplies a large part of the demands of the kingdom, both for beds and for pens. The feathers are plucked from the birds at three, four, sometimes five different periods in the course of a year. This is thought a barbarous custom; but the charge of cruelty is denied by the breeders, who assert that, for their own profit, they pluck only those feathers which are so near falling off as to occasion little pain; those more firmly fixed, and which have some portion of blood at their end, being of very inferior value. The young ones are plucked as well as the old ones; experience having taught that, when plucked early, the future growth of the feathers becomes greater. During the breeding season, the birds are lodged in the same houses as their owners, in wicker pens, which are arranged in rows, frequently in the bed-chambers. A gooseherd in attendance on the flock leads them daily to water, and assists them, on their return, to get into their several cells. The attendants are acquainted with each individual goose in the flock, and can commonly distinguish them by the tones of their voices. Near Spalding there is a considerable heronry, and a smaller one near Surflet, where the herons, like rooks, build their nests on high trees.

The air in the fens is generally insalubrious, and the inhabitants suffer much from the nature of the water, which is generally of a brackish quality; and though they make reservoirs to preserve rain water, in dry summers they experience very great distress. In warm weather, vast swarms of insects add to the annoyances peculiar to this district.

The population, according to the returns at the four decennial enumerations, appear to have amounted in 1801 to 208,557, in 1811 to 237,891, in 1821 to 283,053, and in 1831 to 317,400. The annual value of the real property, as taken in 1815, amounted to L.2,061,830.

The burials, including both the registered and the unregistered, in the period from 1821 to 1831, appear to have been one in 53 of the whole number of inhabitants then living. The illegitimate births were one in nineteen of the whole born.

The occupations of the inhabitants, according to the returns arranged by Mr Rickman in 1831, were as follow:

Occupiers of land employing labourers	6,901
Occupiers of land not employing labourers	6,204
Labourers employed in agriculture	32,167
Labourers employed in manufactures	167
Employed in retail trade or handicraft	20,490
Capitalists, bankers, &c.	2,734
Labourers not agricultural	5,855
Other males twenty years of age	3,886
Male servants	1,848
Female servants	16,011

The towns containing more than 2000 inhabitants, and their population in 1831, were—

Lincoln, city	11,892
Boston, town	11,240
Lowth	6,927
Gainsborough	6,658
Stamford	5,837
Grantham	4,590
Grimsby	4,225
Horncastle	3,988
Holbeach	3,890
Long Sutton	3,510
Sleaford	2,450
Bourn	2,355
Crowland	2,268

The reform bill has left the city of Lincoln, and the boroughs of Boston, Stamford, and Grantham, with two members each, as before. It has left Grimsby with only one; and has divided the county into two districts, one called the Part of Lindsey, and the other the Part of Kesteven and Holland. The polling places for the former are Lincoln, Gainsborough, Epworth, Barton, Brigg, Market Rosin, Louth, Spilsby, and Horncastle; and for the latter, Sleaford, Boston, Holbeach, Bourn, Donington, Navenby, Spalding, and Grantham.

The capital of this county is the see of a bishop, whose jurisdiction is the largest of any in England, extending over the counties of Lincoln, Leicester, Huntingdon, Bedford, and Buckingham; over one half of Hertfordshire, and several portions of Oxfordshire, Berkshire, Rutlandshire, Northamptonshire, and Warwickshire; and including 1517 parishes, under the superintendence of six archdeacons.

The fens of Lincolnshire have running through them wide ditches, which serve to drain the water from the land, and which, when united and extended, become navigable, and highly beneficial as means of conveying the productions to the various markets. The Foss Dyke, the earliest canal made in Britain, was constructed in the year 1121, to form a connection between the city of Lincoln and the river Trent; and though, from the nature of the soil, it has been often obstructed, and the expense of keeping it in order has been great, it has continued to be used from that time to the present day. The river Trent, though rising in Staffordshire, may be considered as a Lincolnshire river, from the principal navigation upon it belonging to this county. It receives the Dun and the Ouse, and, before reaching the sea, unites with the Humber. It is navigable for large barges to Gainsborough. It has, upon the influx of the tide, a most extraordinary *bore*, or, as it is provincially termed, *eager*, when the waters run up resembling a wall with a rapidity that has no equal in any of our English rivers, except the Wye at Chipstow. The Witham rises within the county, about ten miles from Stamford. The early part of its course is through a beautiful district till it reaches the fen country, when its course becomes sluggish; but being navigable to Boston, it is highly beneficial both for draining and for commerce. The other rivers are the Ancholme, the Welland, the Glen, the Grant, and the Ouse. The Humber, indeed, is its boundary on part of the northern side; but is more commonly and properly considered as a Yorkshire than a Lincolnshire river, from Hull, its principal port, being in that county. Two small canals communicate with the river Witham, one from Horncastle, and the other from Sleaford.

The great bay or estuary into which the different rivers and dykes that drain the fens are disembogued, is very shallow, and filled with drifting sands, which render the approach to the shore highly dangerous. The rivers are constantly loaded with mud, and, in times of flood, encounter the tide, equally charged with its floating silt, which causes a stagnation and deposit that is constantly shifting its position, as the strength of the rivers or of the tides happens to be the more powerful.

The face of the country in the fens is generally uninteresting, exhibiting extensive plains, with nothing to break the continuity of the line of vision, and only rendered less monotonous by the vast numbers of cattle with which the green meadows are covered. On the wolds a more bleak and dreary prospect presents itself; but the western division of the country near Stamford and Grantham is variegated, woody, and undulating, and presents generally pleasing pictures.

The agriculture of the fens is of the simplest kind; for where nature has created such a productive soil, little remains to be done by the operations of man. In the more elevated parts of the county the cultivation is conducted with various, but, on the whole, good judgment; and the land produces ample crops of wheat, oats, barley, and beans, and in some parts hemp and flax. The attention, however, of the whole county is more turned to derive profit from cattle than from the use of the plough.

The oxen of Lincolnshire are proverbial for their goodness. The original race were of a great size, with large heads and short horns, thick in the bone, deep in the belly, short on the neck, high on the rump, and bare on the shoulders; but these have been improved by such various and judicious crossings of breeds, that their symmetry and excellent qualities render them the best in the island. Many cattle bred in other countries are fattened here on the rich natural pastures; but a portion of oil-cake is very commonly given, to fit them earlier for the market of Smithfield, to which numerous droves are weekly despatched. This fattening of cattle for the supply of London is so advantageous that the dairy is almost everywhere considered as a secondary object.

The sheep of this county are almost peculiar to it. They are of a large size, have horns, and produce heavy fleeces of long wool, highly prized in the manufacture of stuffs and some kinds of baizes. The flesh is, however, rank in flavour, and, unless the animals are improved by crossing with other races, is not generally relished. As the foundation of an excellent breed, they were selected by the late judicious Mr Bakewell, who, from mixing them with other races, produced those excellent sheep known by the name of the new Leicesters. The fleeces of the pure Lincolnshire sheep in general weigh from ten to twelve pounds; but extraordinary instances have been known in which they have attained more than twenty pounds.

The live stock, in which this county exceeds every other, is rabbits, which the numerous warrens on the wolds produce in vast numbers. From their prodigious quantity, the flesh is of small value, and the sale of the skins for the use of the furriers and hatters is the principal source of profit. The number of warrens has considerably diminished of late years, and the land they occupied has been appropriated to tillage ; but they are still very extensive.

Lincolnshire is not a manufacturing county. Before the extension of machinery, the spinning of their native wool gave occupation to the female part of the population ; but that employment has been nearly discontinued of late years, and no other has yet been substituted in its place. In some parts the flax is spun for domestic use. The nature of its sea-shores operates to prevent foreign commerce; and there is little or no intercourse between Lincolnshire and the ports even of Holland and Germany, which are opposite to it. The county produces neither minerals nor coals.

The antiquities of Lincolnshire are numerous, Almost all the churches are fine specimens of ancient architecture, a singularity which distinguishes them from those in every other county of England. The remains of Crowland, founded in 716, the seat of a mitred abbot, and anciently a place of great fame, are still visited by every antiquary; and near them is the triangular bridge over three streams, in good preservation. It is, however, so lofty and precipitous, that it is only useful to horse and foot travellers, as carriages usually pass under it. The other most prominent antiquities are, Torksey Castle, at the junction of the Foss Dyke with the Trent; Thornton Abbey, near the Humber; Bardney Abbey, on the banks of the Witham ; Tattershall Castle, on the same river ; and Somerton Castle, in the parish of Boothby.

Sir Isaac Newton, Lord Burghley, Lord Bolingbroke, Stukeley the antiquarian, and Wesley, the founder of Methodism, were, amongst many other eminent men, natives of this county.

The most remarkable seats of noblemen and gentlemen are, Blankney, Charles Chaplin, Esq.; Brocklesby Park, Lord Yarborough ; Coleby Hall, Earl Lindsey ; Gautby, Robert Vener, Esq. ; Grinsthorpe Castle, Lord Gwydir ; Hanby Hall, Sir William Manners ; Harmston, Samuel Thorold, Esq. ; Hainton Park, G. Heneage, Esq. ; Nocton Park, Earl of Ripon ; Belton House, Lord Brownlow ; Normanby Hall, Sir J. Sheffield ; Reevesby Abbey, late Sir Joseph Banks ; Subton, Sir Robert Heron ; Summer Castle, Lady Wrey ; Syston, Sir John Thorold ; Thurgunby, Lord Middleton.

LINDESFARN, or **Landisfarn**. See Holy-Island.

LINDSAY, Sir David, a Scotish poet of high reputation, descended from a younger branch of the family of Lord Lindsay of Byres, was the eldest son of David Lindsay, who possessed the estate of Garmylton in the county of Haddington, and that of the Mount in the county of Fife. The honour of the poet's birth belongs to Fifeshire,[1] but the date has not hitherto been ascertained. It appears that a student of the same name was admitted at St Andrews in the year 1505 : if we suppose this to be the same individual, and further suppose him to have been admitted at the age of fifteen, his birth is thus referred to the year 1490. This youth, whoever he may have been, was still a member of the university in 1508. Lindsay's father was then dead, and had left five sons. One of his biographers has sent him, after completing his academical studies, to prosecute his travels through England, France, Italy, and Germany ;[2] but this account seems to rest upon mere conjecture, rather than historical evidence. He himself informs us that he had travelled through divers countries, and he particularly mentions the appearance of the ladies in Italy ; but that he had visited those countries in his youth, is neither stated by himself, nor by any early writer with whom we are acquainted. When first employed in the king's household, he appears to have been still a very young man : in a poem addressed to James the Fifth, he takes occasion to state that he had entered into his majesty's service on the very day of his nativity, that is, on the 12th of April 1512. In the following year, we find him described as a " special servant" to that prince's father ; whom he attended at Linlithgow when a supposed apparition warned the devoted monarch of his approaching fate.[3] The tutor of the young king was Gavin Dunbar, afterwards archbishop of Glasgow, and chancellor of the kingdom.[4] The situation of Lindsay was that of a superior attendant : he is first described as usher to the prince, and afterwards, for several successive years, as the king's master usher. His wife, Janet Douglas, had for many years the charge of the king's linen.[5] In the dedication of his Dreme, he reminds James of the faithful services which he had rendered him in the tender years of his infancy ; and in the " Complaynt directit to the Kingis Grace," he prosecutes the same topics.

Lindsay was afterwards dismissed from his office ; and this event is supposed to have taken place in the year 1524, when the earl of Angus, who had married the queen dowager, regained his influence at court, and introduced such changes as were most conducive to his private views. His former services were not however forgotten, for he acknowledges that his pension continued to be regularly paid. Not satisfied with such a remuneration, he took occasion to bring his own merits under the king's review, and to acquaint him with his disposition to accept of any better preferment. In the Complaynt to which we have already referred, he contrived to convey a hint how a peerage might be very suitably bestowed. It is therefore sufficiently evident that this poet was not deaf to the calls of ambition, and that any addition to his rank or fortune would have been very acceptable. As he seems to have inherited a competent estate, and was not burdened with the maintenance of a numerous family, it is not easy to feel any deep sympathy for his disappointments and mortifications. The wants of a courtier, placed in such circumstances, are of so artificial and factitious a kind, that he must generally be left to bewail his own misfortunes. His remonstrances were not however ineffectual; he at length obtained an office of some dignity and emolument, that of chief herald, quaintly denominated lion king at arms. He afterwards received the honour of knighthood. In his new capacity, he was connected with various embassies. In the year 1531, he was employed in a mission to the emperor Charles the Fifth, whom he found residing at Brussels: this mission had a reference to the commercial intercourse between Scotland and the Netherlands. When the king afterwards became anxious to find a suitable consort, Lindsay repeatedly visited the continent: in 1535 he was connected with one embassy, which solicited a princess of the imperial family, and in the ensuing year with another, which solicited a daughter of the duke of Vendôme; but neither of those negotiations was followed by a treaty of marriage. The young and handsome prince next repaired to France as the bearer of his own proposals; and having soon attracted the warm regard of the king's daughter Magdalene, he married this sickly princess, who died within forty days after her arrival in Scotland.[1] The public joy was thus converted into public mourning; and on this melancholy event Lindsay composed a poem entitled "The Deploratioun of the Deith of Quene Magdalene." She died on the seventh of July 1537, and after an interval of eleven months James received another wife from the same country.

---

[1] Andrew Robertson, in the preface to the Danish translation of Lindsay's poems, informs us that he was born in the county of Fife. " Hand vaar födt i Skotland vdi Fyff Stict."

[3] Buchanani Rerum Scoticarum Historia, p. 251. Lindsay's History of Scotland, p. 111.

[4] The subsequent entry occurs in the Treasurer's Accounts, 28th August 1517 : " Item to Maister Gawan Dunbar, the kingis maister, for expensis maid be him in reparaling of the chalmer in the quhilk the king leris now in the castell, iij. li."

[5] The Treasurer's Accounts contain many notices of Lindsay and his wife. Under the date of 1522, we find the following entry : " Item to Jonet Douglas, spous to Dauid Lindesay, maister ischeare to the king, for sewing of the kingis lynning claithis, de mandato domini gubernatoris, xxiiij. li." And under that of 1526 : " Item gevin that samyn to Dauid Lyndsays wife to sew the kingis sarkis v dowble hankis gold, l. s." She is then mentioned as " Jonet Dowglas, semestair of the kingis lynyng claithis." In 1537 she still had the charge of " the kingis sarkis ;" for under that date occurs the subsequent " Item, to Jonet Douglas, the spous of Dauid Lindesay of the Month, at the kingis grace command, as the precept beris, xl. li."

The reformation was now advancing with gradual steps; and Sir David Lindsay may certainly be classed among those who contributed to accelerate its progress: his writings tended to prepare the public mind for a systematic attempt to overthrow the papal superstition, and to introduce a more pure and rational form of worship. A species of devotion which rather engages the senses than the understanding, and which substitutes unmeaning observances for the vital power of religion, must always be regarded as having proceeded through a polluted channel. But the lives of the ecclesiastics were not less exposed to animadversion than their creed; nor was Lindsay destitute of skill in selecting proper topics of ridicule. His satire, and particularly his dramatic satire, must have had no inconsiderable effect in fostering the rising spirit of contempt for the clergy and their doctrines; and the papists were long disposed to number him among their most formidable enemies.[2] Nor was his ridicule entirely confined to his compositions. The king being one day surrounded by a numerous train of nobility and prelates, Lindsay declared himself a candidate for an office that had lately become vacant. "I have," said he, "servit your grace lang, and luik to be rewardit as others are; and now your maister taylor, at the pleasure of God, is departit; wherefore I wald desire of your grace to bestow this little benefite upon me." The king replied that he was amazed at such an application from a person who could neither shape nor sew. "Sir," rejoined the poet, "that maks nae matter; for you have given bishoprics and benefices to mony standing here about you, and yet they can nouther teach nor preach; and why may not I as weill be your taylor, thocht I can nouther shape nor sew, seeing teaching and preaching are nae less requisite to their vocation than shaping and sewing to ane taylor." James immediately perceived the object of his application, and did not scruple to amuse himself at the expense of the indignant prelates.[3]

Of the king he always speaks in terms of affection, though his admonitions are sometimes not very ceremonious. He was one of the few courtiers who witnessed the melancholy termination of his short career: oppressed by that sickness of heart which arises from a consciousness of fatal misconduct, James expired in the royal palace of Falkland on the 14th of December 1542, when he had only attained the thirty-first year of his age. The earl of Arran was soon afterwards appointed regent of the kingdom; and Lindsay is enumerated among those who adhered to him while he continued to act in conformity to the principles which they avowed. He was a member of parliament for the borough of Cupar in 1543, and the three succeeding years; and in 1544 he was again sent on an embassy to the emperor, for the purpose of delivering into his hands the insignia and statutes of the order of the Golden Fleece, which had been conferred on the late king. After an interval of four years, we find him employed on an embassy to Christian king of Denmark. One of his biographers avers that at Copenhagen he became acquainted with his countryman Dr Machabæus, and other men of learning,[4] nor is the supposition destitute of probability;

[3] H. Charteris's pref. to the Warkis of the famous and worthie knight Sir Dauid Lyndsay of the Mont, alias Lyoun King of Armes. Edinb, 1582, 4to.—Of this very rare edition there is a copy in the Advocates Library. It was "imprentit at Edinburgh be Henrie Charteris;" and contains the same poems as the edition of 1592. The table of contents on the reverse of the title includes the Historie of Squyer Meldrum, which is not however to be found in the volume.

[4] Chalmers's Life of Lindsay, p. 37.—The name of Machabæus is otherwise connected with that of Lindsay. Ane Dialog betuix Experience and ane Courteour, off the miserabyll Estait of the Warld: compylit be Schir Dauid Lyndesay of the Mont, Knycht, alias Lyone Kyng of Armes, and is deuidit in foure partis, as eftir followis, &c. and imprentit at the command and expensis of Doctor Machabevs, in Copmanhouin, 1552, 4to. This first edition of the poem is however supposed to have been printed, not at Copenhagen, but at St Andrews by John Scott. John Machabæus, whose family name was Macalpine, was driven from Scotland by the persecution (Knox, p. 20.), and having sought refuge in Germany, he prosecuted his studies at Wittemberg and Cologne. At the suggestion of Melanchthon he adopted the name of Machabæus Alpinas. He took the degree of B.D. at Cologne; and on being appointed professor of divinity at Copenhagen in 1542, he took the degree of D. D. Here he died in the year 1557. (Worms Forsög til et Lexicon over Danske, Norske, og Islandske lærde Mænd, Bind ii. S. 2. Kiöbenhavn, 1771-84, 3 Bind. 8vo. Nyerups Al-

but it is always dangerous and always reprehensible to substitute mere conjecture for historical evidence.

Sir David Lindsay had decidedly espoused the cause of the reformers before they had become very formidable to the government; and it may perhaps be considered as remarkable that he escaped every species of persecution. In the year 1546, Cardinal Beaton, a prelate whose glaring vices were redeemed by very few virtues, was murdered in his own castle by a band of conspirators, who were partly instigated by private animosity, partly by public spirit, and who must all have been accustomed to contemplate without compunction this desperate method of inflicting punishment or perpetrating revenge. They were possessed of sufficient resources to garrison the castle of St Andrews, and to defend it against the royal forces for the space of fourteen months. To this strong hold John Knox repaired at Easter 1547; and at a conference which was there held, Lindsay was one of those who recommended the ordination of this distinguished individual,[1] in whom his penetration had doubtless discovered that energy of mind which qualified him for the arduous task that he was destined to perform.

The period of Lindsay's decease has not been ascertained. On the 17th of January 1555 we find him holding a chapter of heralds, for the purpose of investigating certain charges against a messenger-at-arms. He appears, according to one account, to have died between this period and the year 1558. As he died without issue, his estates descended to his brother Alexander; and they have long ceased to be inherited by the family of Lindsay.

Beside his poetical works, the chief foundation of his fame, he composed several others of less general interest. The nature of his office directed his attention to a species of knowledge which human folly has dignified with the name of science; and on the subject of heraldry he has left two different productions, one of which still continues in manuscript,[2] and the other, a curious collection of Blazonings, has lately been given to the public.[3] Bale informs us that he composed "Acta sui Temporis,"[4] and Mackenzie affirms that he was the author of a history of Scotland. For this statement he quotes the authority of Robert Lindsay of Pitscottie; who however refers to Sir David Lindsay, the knight of the Mount, and other individuals, as those from whom he had derived private information. Dr Leyden supposes Lindsay to be the author of the Complaynt of Scotland; but we have never yet met with a single enquirer who professed to be convinced by his arguments.

It is the poetry of Lindsay that chiefly recommends him to our notice, and he appears with no inconsiderable distinction in the literary annals of his country. Vernacular poetry was most successfully cultivated in Scotland when it was in a great measure neglected in England. An English critic of unquestionable taste has remarked that "the interval between the reigns of Henry V. and Henry VIII. which comprehends near a century, although uncommonly rich in Scotch poets of distinguished excellence, does not furnish us with a single name among the natives of England deserving of much notice."[5] When England produced only obscure versifiers, Scotland could boast of King James, Henry the Minstrel, Henryson, Dunbar, Douglas, Lindsay, and various other writers of genius. Sir David Lindsay has written so many verses that they cannot always be expected to reach a very high standard: his works indeed exhibit considerable inequalities; but where they are not distinguished by any superior force of imagination, they are often entertaining by their strokes of humour, or instructive by their views of life and manners. He was evidently a man of sense and observation, with serious impressions of virtue and piety; nor was he destitute of those higher powers of mind which enable a writer to communicate his ideas with effect. He frequently displays no mean vivacity of fancy; and the extensive and continued popularity to which he attained, must have rested on some solid foundation. Many of his poems have a satirical tendency; and the freedom with which he exposes vice, even when it belongs to royalty, has stamped his works with the character of intrepid sincerity. Of the state of society and manners, Lindsay presents us with many curious pictures; and although his delineations are sometimes extremely coarse, they are not on that account to be considered as less faithful. In this respect, his writings possess a peculiar value, and ought to be carefully examined by those who particularly direct their attention to the history of that period. The author's talents seem to have been cultivated with considerable assiduity: he was much conversant in history and divinity; and his knowledge of Latin writers, ancient as well as modern, was apparently respectable. His acquaintance with Grecian literature may perhaps be called in question: he denominates Hesiod the sovereign poet of Greece; a character which he could scarcely be expected to receive from any person acquainted with the language of Homer. Lindsay's versification is generally distinguished by its ease and fluency. His style often rises to a considerable degree of elegance, but on many occasions is overloaded with extraneous terms. This vicious taste was indeed too prevalent in both kingdoms: Hoccleve, Lydgate, and other successors of Chaucer, who possessed but a small portion of Chaucer's genius, endeavoured to render their diction poetical by the easy expedient of garnishing it with affected words, chiefly polysyllables of Latin origin; and the manner in which those words were applied, imparted a vague and tautological character to their most elaborate compositions. Dunbar, Douglas, and Lindsay were all infected with the prevailing taste, and have all exhibited specimens of this vitiated style. "It does not," says Dr Nott, "occur so frequently in Lindsay as in his contemporaries, because perhaps his subjects were mostly those of common life. Still, as it is to be found in those passages which aspire to elevation of thought, we must conclude him to have considered it the proper language of the higher walks of poetry."[6] This remark might be verified by many quotations from his poems; where we find

---

mindeligt Litteraturlexicon for Danmark, Norge, og Island, S. 367. Kiöbenhavn, 1820, 4to.) He was respected for his learning, and is the author of some professional tracts, which are enumerated by these literary historians. His son Christian Machabæus, born at Wittemberg in 1541, published several Latin works in prose and verse. His last preferment was a prebend at Lund, where he died in 1598.

[1] Knox's Historie of the Reformatioun of Religioun, p. 67.

[2] Both his MSS. are preserved in the Advocates Library. That which is still unpublished bears the following inscription in the hand-writing of Sir James Balfour: "Collectanea Domini Dauidis Lindesay de Mounthe, Militis, Leonis Armorum Regis." Of this heraldic compilation a copious specimen has been inserted in Dr Leyden's Dissertation on the Complaynt of Scotland, p. 55. There is another MS. which the catalogue ascribes to the same author, but which evidently belongs to one of his successors.

such terms as formose, matutyne, mansweit, prepotent, consuetude, celsitude, pulchritude, immundicitie, and many others of a similar denomination.

The longest of his poems is entitled "Ane Dialog betwix Experience and ane Courteour, of the miserabill Estait of the Warld." This poem, which is otherwise described as the Monarchie, is indeed of great length: it is not however, as has sometimes been asserted, a tedious detail of well-known events, but a work replete with various learning, and enlivened by the remarks of an acute and reflecting mind. It appears to have been composed when the author had reached an advanced age, and may therefore be regarded as the result of much reflection on human life. It has been unfaithfully characterized as a meagre compendium of universal history: the poet's principal object is not to detail events, but, by referring to the great occurrences recorded in sacred and profane history, to illustrate general positions; and notwithstanding the great extent of his work, he can seldom be considered as languid or tedious. A Latin translation of the Monarchie was undertaken by David Carnegie of Aberdeen, who did not however live to complete the task.[1] The poem was translated into English, and repeatedly printed in London; and, along with other works of the author, was translated into Danish, and published at Copenhagen in the year 1591. The process of converting Lindsay's compositions into this language was somewhat peculiar: they were first translated into Latin prose by Andrew Robertson, and were afterwards translated into Danish verse by Jacob Mattssön.[2]

Lindsay's Dreme, which is supposed to be his earliest, has likewise been regarded as his most poetical composition. In the opinion of Warton, the prologue to this poem evinces strong talents for high description and rich imagery. His Complaynt, which is likewise addressed to the king, is a valuable and interesting production: it exhibits some lively sketches of the author's personal fortunes, of the prevalent manners of the times, and of the early history of James the Fifth. The mode in which the tender age of this hopeful prince was corrupted by the designing profligacy of his attendants, is painted in striking colours; and although the information is conveyed in rhyme, it seems to be nearly allied to historical accuracy. James was possessed of superior talents, and of a disposition capable of receiving a virtuous direction; but his education was interrupted at a critical period, and he was early initiated in vice by those who by every tie of decency were bound to inculcate the lessons of virtue. The king was himself a lover of poetry, and his court was frequented by poets: Lindsay and Bellenden belonged to the royal household; and he had sufficient discernment to appoint Buchanan the tutor of one of his natural sons. From Lindsay's "Answer to the Kingis Flyting," it appears that James was a writer of verses: he begins by stating that he had read his majesty's *ragment*, and proceeds to compliment him on his "ornate meter," proclaiming him the prince of poetry.

The "Supplication directit to the Kingis Grace, in contemptioun of side Taillis," is at least conspicuous for the author's zeal as a reformer of manners. He seems to have contemplated long trains and veiled faces with an unnecessary degree of alarm; but, like a good Christian, he recollected that a long train proceeds from pride, and pride from the devil. He is chiefly scandalized at observing nuns and other religious persons followed by trainbearers. Nor is he less offended with the "muzzled faces" of the ladies. The queen is the only female whom he proposes to exempt from the necessity of shewing her face and curtailing her gown. Kitteis Confession, another of his satirical poems, contains many happy strokes of humour. It is directed against auricular confession, a copious source of priestly influence; and the practice is exposed with equal pungency and good sense. The damsel remarks that her ghostly instructor gave her no injunctions to lead a holy life, and to confide in the merits of Christ, but only to follow certain external observances, of which she ventures to doubt the efficacy:

> Bot gave me pennance ilk ane day,
> And Ave Marie for to say,
> And frydayis fyve na fische to eit—
> Bot butter and eggis ar better meit;
> And with ane plak to by ane messe
> Fra drunkin Schir Jhone Latynlesse.

The sanctified lasciviousness of the father confessor is depicted with no unskilful pencil. But the impurities of the Romish church were exposed to a more formidable attack, in "The Testament and Complaynt of our Soverane Lordis Papingo;" a singular performance, in which he admonishes the king and his courtiers, and exposes the corrupt doctrines and vicious lives of the clergy. "In the course of the poem before us," says Mr Warton, "an allegory on the corruptions of the church is introduced, not destitute of invention, humour, and elegance; but founded on one of the weak theories of Wickliffe, who, not considering religion as reduced to a civil establishment, and because Christ and his apostles were poor, imagined that secular possessions were inconsistent with the simplicity of the gospel."[3] But if we recollect what precious fruits both Wycliffe and Lindsay had seen produced by this civil establishment of religion, it is by no means wonderful that they should have adopted such a theory. The clergy enjoyed a very large proportion of the wealth of both kingdoms, and they doubtless exhibited different degrees of piety and learning; but it cannot be denied that their profligacy bore some proportion to their opulence, and that true and vital religion, that religion which affects the heart and influences the conduct, was in a great measure supplanted by idle and unavailing ceremonies. In the Tragedie of the Cardinall, this zealous reformer still prosecutes the same design. The plan of the poem bears some resemblance to that which was afterwards adopted in the Myrrour for Magistrates. As the author, after the hour of prime, is sitting in his oratory and reading the work of Boccaccio *De Casibus Virorum illustrium*, he suddenly perceives the figure of a wounded man, with pale visage and deadly cheer. This visitor, who proves to be the ghost of Cardinal Beaton, entreats him to commit his tragic story to writing; and on his assenting to this proposal, the woe-begone cardinal begins a relation of the principal events of his wicked life; but the story is not told with much elegance or energy.

[1] Gray, Oratio de illustribus Scotiæ Scriptoribus, p. xxxi.

[2] Dialogvs, eller en Samtale imellom Forfarenhed oc en Hofftienere, om Verdens elendige Væsen, oc begribis vdi fire Böger om Monarchier: fordum screffuen paa Skotske, aff velbyrdige Herre Herr Dauid Lyndsay, Ridder de Monte, etc. oc nu nylige transfererit aff Skotske Maal paa Latine ved Anders Robertson, födt i Aberdijn i Skotland, oc siden aff Latine paa Danske Rijm ved Jacob Mattssön Kiöbenhaffn, o. s. v. Prentit i Kiöbenhaffn, 1591, 4to.—This very curious volume includes a translation of the Monarchie, the Dreme, the Complaynt, the Testament and Complaynt of the Papingo, the Tragedie of the Cardinall, and the Deploratioun of Quene Magdalene. Robertson has prefixed a preface, which is chiefly derived from that of Charteris; and he has adopted the Scotish printer's Adhortatioun, with some slight adaptations to the Danish public. From the peculiar process followed in this translation, we can scarcely expect it to be uniformly correct. Charteris, in his preface, mentions the execution of "the vicar of Dolour, Freir Kelour," and others. Friar Kelour was no doubt translated by Robertson *Frater* Kelour; Mattssön has translated it "hans Broder Kelour," and thus we have the vicar of Dollar and his brother. Andrew Robertson was a native of Aberdeen, and prosecuted his studies in the university of Copenhagen. He is the author of some Latin poems, which have escaped the notice of Nyerup. (Almendeligt Litteraturlexicon for Danmark, Norge, og Island, S. 499.) The name of Jacob Mattssön or Madsen occurs in the history of Danish poetry written by Nyerup and Rahbek. (Bidrag til den Danske Digtekunsts Historie, Bind ii. S. 88. Kiöbenhavn, 1800–19, 5 Bind. 8vo.)

[3] Warton's History of English Poetry, vol. iii. p. 149.

Lindsay has evinced his humour and good sense in ridiculing practices of another kind. One of the most barbarous usages connected with chivalry was the exhibition of tournaments, in which it frequently happened that the valiant knights displayed their courage and address at the expense of their lives; and the ladies of the middle ages attended these spectacles with nearly as little compunction as the ladies of the present age attend the representation of a tragedy at Drury Lane. It was however during the decline of chivalry that Lindsay produced his facetious account of "The Justing betwix Watsoun and Barbour." He represents this justing to have taken place at St Andrews between two gentlemen of the king's household: they are both described as adepts in physic; and as envy is apt to arise among those who follow the same calling, the subject of the poem was probably suggested by the feuds and jealousies which subsisted between these gentle leeches.

One of the author's most entertaining works is the Historie of Squyer Meldrum, which is to be considered as a tale of chivalry, although the champion and the poet flourished at the same period. Lindsay professes to have derived some part of his information from the hero of his story; and the romantic adventures of William Meldrum were yet fresh in the recollection of his countrymen. By assimilating him to the heroes of classical antiquity and of more recent romance, he has imparted to his work a certain air of fiction. With the romantic he has occasionally blended a sufficient mixture of the ludicrous. It is nevertheless to be presumed that much of his narrative is substantially true; and some parts of it can be verified from other authorities. After the exploits of his youth, the heroic squire fixed his residence in Fife, where he possessed an estate, and was appointed the deputy of Patrick Lord Lindsay, sheriff of that county. Here he is said to have administered justice in an exemplary manner, and to have dispensed physic as well as law to the poor. The desperate wounds which he himself had received directed his attention to the healing art; and as ardour was the essence of his character, he seems to have engaged in this new pursuit with his wonted enthusiasm. It is therefore evident that the squire was a person of a very singular character, and his exploits have furnished his friend, the knight of the Mount, with materials for a long and entertaining poem. In the course of his adventures, Meldrum arrives at a castle in Stratherne, and falls in love with its beautifull owner, a young widow, who had been married to his own relation, apparently a cousin. Being conducted to his bedchamber, he continues to meditate on her charms, and at length begins to vent his passion in loud ejaculations: from her own apartment the lady overhears this soliloquy of her heroic guest, and speedily arrives at the conclusion that such ardent love ought to be duly requited. We learn from Lindsay of Pitscottie that she bore him two children, and their marriage was only deferred till they should obtain a dispensation from the pope; for her deceased husband was related to the squire within the prohibited degrees.[1] It does not however appear that the dispensation was ever obtained; and in the mean time "a gentleman called Luke Stirling, envied this love and marriage betwixt thir two persons, thinking to have the gentlewoman to himself in marriage, because he knew the laird might not have the pope's licence by the laws: therefore he solisted his brother's son, the laird of Keir, with a certain company of armed men, to set upon the laird of Binns, to take this lady from him by way of deed; and, to that effect, followed him betwixt Leith and Edinburgh, and set on him beneath the Rood chapel with fifty armed men; and he again defended him with five in number, and fought cruelly with them, and slew the laird of Keir's principal servant before his face, defending himself, and hurt the laird, that he was in peril of his life, and twenty-six of his men hurt and slain; yet, through multiplication of his enemies, he was overset and driven to the earth, and left lying for dead, hought of his legs, and stricken through the body, and the knops of his elbows stricken from him. Yet, by the mighty power of God, he escaped the death, and all his men that were with him, and lived fifty years thereafter."[2]

But the most remarkable of Lindsay's productions still remains unnoticed; namely, his "Satyre of the thrie Estaits, in commendation of vertew and vituperation of vyce." Of the genuine Scottish drama this is the earliest specimen that is now to be found. It does not appear that he was the author of any other work of this description, though it is probable that the same play was somewhat modified for different representations. This play is said to have been acted at Cupar in the year 1535; and it appears to have been acted before the king and his court at Linlithgow in the year 1539. It was likewise "playit beside Edinburgh, in presence of the quene regent and ane greit part of the nobilitie, with ane exceiding greit nowmer of pepill, lestand fra nyne houris afoir none, till six houris at euin." Spectators who retain their places for the space of nine hours, must certainly meet with no slight degree of entertainment; but it appears from one of the stage-directions that the play was divided into two parts, and that they had thus an opportunity of taking some refreshment during a short pause in the representation. Lindsay's Satyre of the thrie Estaits is a morality, containing a mixture of real and allegorical characters, and cannot therefore be expected to exhibit a succession of very probable incidents. It however exhibits some curious germs of the dramatic art; and in reference to those to whom it was originally addressed, it must be regarded as a powerful satire. The principal burden of his satire falls upon the ecclesiastics. It contains an extraordinary mixture of piety and obscenity; and without approaching to the model of a regular drama, it furnishes many unequivocal proofs of the author's ingenuity. As a dramatic composition, it is not necessary to specify its defects, which are indeed sufficiently obvious: Lindsay must however be compared, not with the poets of a later age, but with those of his own; the contemporary history of English poetry presents to us no dramatic work equal to the Satyre of the thrie Estaits. Of this play there is an appendage, apparently written by the same author, which yet remains to be noticed: it is entitled the "Proclamatioun of the Play, maid be Dauid Lindsay." This proclamation is itself a dramatic entertainment, consisting of a few pages, and intended to announce that the play was to be acted on the castle-hill of Cupar on a particular day. Newspapers and play-bills were not then invented; and this was evidently a device for collecting a crowd of people on the market-day, in order to disperse the intelligence.

---

[1] In the civil law there were various fluctuations with respect to the marriages of cousins-german; and the reader, who is desirous of prosecuting such researches, will find ample information in the dissertation of Gothofredus, De Nuptiis Consobrinorum, subjoined to his edition of Philostorgii Historia Ecclesiastica, Genevæ, 1643, 4to, and in Otto's Dissertationes Juris Publici et Privati, p. 79. Traj. ad Rhen. 1723, 4to. The law of Justinian stood thus: "Duorum autem fratrum vel sororum liberi, vel fratris et sororis, jungi possunt." (Inst. lib. i. tit. 10. § 4.) The canon law has adopted a different doctrine: prohibitions introduce the necessity of dispensations; dispensations increase the influence and the emoluments of the church. It even prohibits the marriage of third-cousins; and, as we have seen in the case of Squire Meldrum, extends its rule to affinity as well as consanguinity. To this discrepancy between the civil and the canon law, as Dr Wood has suggested, we may trace the origin of a vulgar notion, still prevalent in this kingdom, that first-cousins may marry, but second-cousins may not. (Institute of the Civil Law, p. 47.) In computing the degrees of consanguinity in the transverse line, the civil and the canon law follow very different methods. The rule of the civil law is, that there are as many degrees as persons, exclusively of the common stock; that of the canon law, that degrees of consanguinity are to be reckoned by the number of descents in one line; and where the lines are unequal, the canonist takes the longer of the two. The canon law prohibits marriages in the fourth, the civil law permits them in the same degree; or, in other words, the one law prohibits the marriages of third-cousins, and the other permits the marriages of first-cousins. It may not be superfluous to mention that the earlier canonists differed from each other in one point: "Alii namque patrem in primo gradu, filios in secundo ponunt. Alii primum gradum filios appellant." (Decretum, p. 2. c. 35. qu. 2 & 3. § 21.) But the decision of pope Alexander the Second, that two degrees in the civil law make one in the canon law, has been generally adopted by later writers. "Qui tamen parens," says Canisius, "gradum non efficit, sed ipsius filius et filia primum gradum constituunt; et ex his filius et filia secundum gradum." (Summa Juris Canonici, lib. ii. tit. xii. § 9.) This decision is however overlooked by Dr Taylor, who describes first-cousins as standing in the third degree of consanguinity, according to the computation of the canon law. (Elements of the Civil Law, p. 331.)

[2] Lindsay's Hist. of Scotland, p. 129. Edinb. 1728, fol.—This fair lady was "called the Lady Gleneagies, who was daughter to Mr. Richard Lawson of Humby, provost of Edinburgh; the which lady had born to this laird two bairns, and [he] intended to marry her, if he might have had the pope's licence, because her husband before and he were sib."

Sir David Lindsay has now maintained his popularity for the space of three hundred years, and his works have been printed in a great variety of forms. The last edition, which makes very extraordinary pretensions to general erudition and to particular accuracy, was published by Mr George Chalmers. Lond. 1806, 3 vols. 8vo. The editor displays a modesty of disposition and an elegance of taste, which are only surpassed by the suavity of his manner and the profundity of his learning. All these topics might afford scope for illustration, but we shall at present confine ourselves to the subject of his erudition, which has been highly extolled by writers nearly as learned as himself. The following line occurs in Ketteis Confession.

Thocht Codrus kyte suld cleue and birst.

"I know not," says the accomplished editor, "if there be any allusion here to either of the Codruses, who are feigned by poets: Lindsay may have alluded to Urceus Codrus, an Italian professor, and poet, of a singular character, who died, in 1500." Vol. ii. p. 214. But if his classical studies had ever proceeded so far as the seventh eclogue of Virgil, he would have had no difficulty in discovering to which "of the Codruses" the poet alludes.

Pastores, hedera crescentem ornate poetam,
Arcades, invidia rumpantur ut ilia Codro.

In vol. i. p. 81. we find the subsequent remarks: "Cocburn's *Meditatio* was printed at St Andrews, by Jhone Scot, in 1555. He calls himself Johannis Scot, in the titlepage, and Johannes Scott, in the colophon." This change from *Johannis* to *Johannes* we can undertake to explain: the title bears "ex typographia Johannis Scot," and the colophon, "excudebat Joannes Scott." The numerous works of this writer betray such a radical ignorance of the Latin language, that we have no doubt of his intending to express his surprise at the variation of the genitive from the nominative case. In another publication, he enumerates "Cicero's Epistles de Senectute, de Amicitio; Terence's Comedies and Elegies; Ovid's Tristium." After meeting with these specimens of his scholarship, we are sufficiently prepared for his commentary on another passage of Lindsay, which alludes to the pretensions of the pope.

His style at lenth gif thow wald knaw,
Thow moste ga luke the cannon law:
Baith in the Sext and Clementene
His staitlie style thair may be sene.

"The allusion," he is pleased to inform his readers, "is to the Works of Pomponius Sextus, the great jurist of the 3d century." Vol. iii. p. 89. Pomponius did not flourish in the third, but in the second century: if however he had actually written in the third century, how could he have illustrated the temporal power and splendour of the pope, before Christianity was established in the Roman empire? The *Sext* to which Lindsay alludes is "Liber *sextus* Decretalium," a portion of the *Corpus Juris Canonici*. See above, vol. vi. p. 94. A further specimen of this editor's acquaintance with literary and ecclesiastical history occurs in the following passage: "We may infer, that the Calvinists were not yet known, as a sect." Vol. i. p. 425. Certainly we may infer that the Calvinists were utterly unknown as a sect in 1535, inasmuch as Calvin, the founder of that sect, did not become a minister and professor at Geneva till the ensuing year.[1] (x.)

LINDSEY, the third and largest division of the county of Lincoln, in England. On the east and north it is washed by the sea, into which it runs out with a large front; on the west it has Yorkshire and Nottinghamshire, from which it is parted by the rivers Trent and Dun; on the south it has Kestoven, from which it is separated by the river Witham and the Foss-dyke, which is seven miles long, and was cut by Henry I. between the Witham and the Trent, for the convenience of carriage in those parts. It derived its name from Lincoln, the capital of the county, which stands in it, and by the Romans was called *Lindum*, by the Britons *Lindcoite*, by the Saxons *Lindo-collyne*, probably from its situation on a hill, and the lakes or woods that were anciently thereabouts; but the Normans called it *Nichol*.

LINDUS, in *Ancient Geography*, a town of Rhodes, situated on a hill on the western side of the island. It was built by Tlepolemus the son of Hercules, according to Diodorus Siculus; but by one of the Heliades, grandsons of the Sun, named *Lindus*, according to Strabo. It was the native place of Cleobulus, one of the wise men. Here was the famous temple of the Lindian Minerva, built by the daughters of Danaus. Cadmus enriched this temple with many splendid offerings. The citizens dedicated and hung up here the seventh of Pindar's Olympic odes, written in letters of gold. The ruins of that superb edifice are still to be seen upon the top of a high hill which overlooks the sea. Some remains of the walls, consisting of stones of an enormous size, still show that it had been built in the Cyclopian style.

Lindo, the modern city, stands at the foot of the hill. A bay of considerable wideness and depth serves as a harbour to the city. Ships find good anchorage there in twenty fathoms water. They are safely sheltered from the south-west winds, which constantly prevail during the severe season of the year. In the beginning of winter, they cast anchor off a small village named Massary. Before the building of Rhodes, Lindus was the harbour which received the fleets of Egypt and of Tyre; and it was enriched by commerce. Mr Savary observes, that a judicious government, by taking advantage of its harbour and happy situation, might yet restore it to a flourishing state.

---

[1] Bayle, Dictionaire Historique et Critique, tom. i. p. 729.

LINE, in *Geometry*, a quantity extended in length only, without breadth or thickness. It is formed by the flux or motion of a point.

LINE, in the art of war, is understood of the disposition of an army ranged in order of battle, with the front extended out, so that it may not be flanked.

LINE of Battle, is also understood of the disposition of a fleet in the day of engagement; on which occasion the vessels are usually drawn up as much as possible in a straight line, as well to gain and keep the advantage of the wind, as to run the same board. See NAVAL TACTICS.

Horizontal LINE, in *Geography* and *Astronomy*, a line drawn parallel to the horizon of any part of the earth.

Equinoctial LINE, in *Geography*, is a great circle on the earth's surface, exactly at the distance of 90° from each of the poles, and of consequence bisecting the earth in that part. From this imaginary line, the degrees of longitude and latitude are reckoned. In astronomy, the equinoctial line is that circle which the sun seems to describe round the earth on the days of the equinox in March and September.

Meridian LINE, is an imaginary circle drawn through the two poles of the earth and any part of its surface.

Ship of the LINE, a vessel large enough to be drawn up in the line of battle, and to have a place in a sea-fight.

LINE, in *Genealogy*, a series or succession of relations in various degrees, all descending from the same common father.

LINES, in *Heraldry*, the figures used in armories to divide the shield into different parts, and to compose different figures. These lines, according to their different forms and names, give denomination to the pieces or figures which they form, except the straight or plain lines.

LINEAMENT, amongst painters, is used for the outlines of a face.

LINEAR NUMBERS, in *Mathematics*, such as have relation to length only; like a number which represents one side of a plain figure. If the plain figure be a square, the linear figure is called a *root*.

LINEAR Problem, that which may be solved geometrically by the intersection of two right lines. This is called a *simple problem*, and is capable of but one solution.

LINEN (in German, *linnen*, *leinwand*), a species of cloth usually made of thread of flax, but sometimes also of hemp. Linen seems to have been known and manufactured in Egypt from the earliest times, and used, if not as an article of ordinary dress, at least in swathing the bodies of the dead. But it was not worn by the Jews, the Greeks, or the Romans, under tunics of a finer texture having amongst them supplied the place of shirts; and hence the necessity of frequent bathing. Alexander Severus was the first Roman emperor who wore linen; but the use of this necessary article did not become common until long after his time.

The manufacture of this commodity has been prosecuted in England for a very long period, probably since the time of the Romans; but though its progress has been considerable, particularly within the last twenty or thirty years, it has not been so great as might have been anticipated. This is no doubt to be ascribed partly to the efforts which have been made to encourage and bolster up the manufacture in Ireland and Scotland, and partly to the rapid growth of the cotton manufacture, the fabrics of which have to a considerable extent supplanted those of linen.

In 1698, both houses of parliament addressed the king, William III., representing that the progress of the woollen manufacture of Ireland was such as to prejudice that of England, and that it would be for the public advantage were the former discouraged, and the linen manufacture established in its stead. His majesty replied that he would do all that in him lay to *discourage* the *woollen* manufacture in Ireland, to encourage the *linen* manufacture, and to promote the trade of England. Nothing can be more strikingly characteristic of the erroneous and illiberal notions which were then entertained respecting the plainest principles of public economy, than this address, and the answer made to it by the sovereign. But whatever the people of Ireland might think of the king of England deliberately avowing his determination to do all in his power to crush a manufacture in which they had made considerable progress, government had no difficulty in prevailing upon the legislature of that country to second their views, by prohibiting the exportation of all woollen goods from Ireland, except to England, where prohibitory duties were already imposed on the importation of such goods. The parliament and government of England, however, though anxious to protect the woollen manufacture of that country, never discovered any backwardness to promote the linen trade of Ireland; and ever since the reign of William III. it has been the object of regulation and encouragement. It may indeed be doubted whether the regulations in question have always been the most judicious that might have been devised, and whether Ireland has really been benefited by the forced extension of the linen manufacture. Mr Young and Mr Wakefield both contend that the extension of the linen manufacture has not been advantageous to that country; and it seems to be sufficiently established, that though the manufacture might not have been so widely diffused, it would have been in a sounder and more healthy state had it been less the subject of legislative interference.

Besides premiums and encouragements of various kinds, bounties were granted on the exportation of linen from an early period down to the year 1830. In 1829, for instance, notwithstanding the bounty had then been very much reduced, it amounted to about L.300,000, or nearly one-seventh of the declared value of the linen exported in that year. It would be difficult to imagine a greater abuse than this. Such a bounty, instead of promoting the manufacture, rendered those engaged in it comparatively indifferent to improvements; and, though it had been otherwise, the policy of persisting, during more than a century, in supplying foreigners with linens for less than they cost, cannot possibly be defended. There is no reason to doubt, that were the various sums expended in well-meant but useless attempts to force this manufacture, added together with their accumulations at simple interest, they would be found sufficient to yield an annual revenue little if at all inferior to the entire value of the linens which we now send abroad. In fact, the business never began to do any real good, or to take firm root, until this manufacture ceased to be a domestic one, and was carried on principally in mills, and by the aid of machinery; a change which the forcing system, so long pursued, tended to counteract. The only real and effective legislative encouragement which the manufacture has ever met with, has been the reduction of the duties upon flax and hemp, and the relinquishment of the absurd attempts made to force the growth of these raw commodities at home.

The following table, which it is to be regretted the parliamentary accounts do not furnish the means of continuing to the present day, exhibits an account of the quality and value of the linens exported from Ireland, during a period of nearly thirty years, from 1800 to 1829 both inclusive.

Years.	To Great Britain.	To Foreign Parts.	Total.	Amount of Bounty paid in Ireland on Linen exported to Foreign Parts.		
	Yards.	Yards.		£	s.	d.
1800	31,978,039	2,585,829	34,563,868	~~~	~	~
1802	33,246,943	2,368,911	35,615,854	~~~	~	~
1804	39,837,101	3,303,528	43,140,629	10,545	2	2
1806	35,245,280	3,880,961	39,126,241	15,668	4	6
1808	41,958,719	2,033,367	43,992,086	6,740	16	0
1810	32,584,545	4,313,725	36,898,270	16,448	19	9
1812	33,320,767	2,524,686	35,845,453	11,548	3	4
1814	39,539,443	3,463,783	43,003,226	17,231	14	11
1815	37,986,359	5,496,206	43,482,565	17,430	17	3
1816	42,330,118	3,399,511	45,729,629	12,082	6	4
1817	50,288,842	5,941,733	56,230,575	21,524	15	4½
1818	44,746,354	6,178,954	50,925,308	28,848	6	2
1819	34,957,396	2,683,855	37,641,251	16,177	8	3½
1820	40,318,270	3,294,948	43,613,218	11,928	9	11
1821	45,519,509	4,011,630	49,531,139	18,218	19	2¾
1822	43,226,710	3,374,993	46,601,703	17,112	9	2
1823	48,066,591	3,196,006	51,235,597	17,765	5	10
1824	46,466,950	3,026,427	49,493,377	17,114	13	10½
1825	52,559,678	2,553,587	55,113,265	12,015	9	6½
1826	The exportations to Great Britain cannot be ascertained for these years, the cross-channel trade having been assimilated by law to a coasting traffic.	2,726,297	....	10,249	17	9
1827		4,284,566	....	12,114	0	8
1828		3,214,911	....	9,494	7	5
1829		2,386,223	....	6,886	1	11

Of these exports more than twelve-thirteenths have been to Great Britain. The total average exportation during the three years ending with 1825, was 51,947,413 yards, of which 49,031,073 were sent to this country; the exports to all other parts being only 2,916,340 yards. Since 1825, the trade between Ireland and Great Britain has been placed on the footing of a coasting trade, so that linens are now exported and imported without any specific entry at the Custom-house.

In 1727, a board of trustees was established in Scotland for the superintendence and improvement of the linen manufacture. It is not probable that the institution of this board could of itself have been of any material service; but considerable bounties and premiums being at the same time given on the production and exportation of linen, the manufacture went on increasing. Still it did not increase as fast as cotton and some others, which received no adventitious support, until machinery began to be extensively employed in the manufacture; and hence it is doubtful whether the influence of the bounty has been as great as it might at first view appear to have been. The regulations as to the manufacture, after having been long objected to by those concerned in it, were abolished in 1822; and the bounties have in like manner ceased.

Dundee is the principal seat of the Scottish linen manufacture, and its progress there has latterly been extraordinary. The manufacture appears to have been introduced into Dundee about the beginning of the last century; but for a long period its progress was comparatively slow. In the year 1745, the quantity of flax imported amounted only to seventy-four tons, without any hemp; and the shipments of linen cloth, during the same year, were estimated at about 1,000,000 yards; but no mention is made either of sail-cloth or of bagging. In 1791, the imports of flax amounted to 2444 tons, and those of hemp to 299 tons; whilst the exports of that year were 7,842,000 yards of linen, 280,000 yards of sail-cloth, and 65,000 yards of bagging. From this period the trade began to extend itself gradually. Previously to the peace of 1815, no great quantity of machinery had been employed in spinning; but about this period, the trade began to increase rapidly, partly in consequence of the improvement of the machinery, and its extensive employment in the manufacture, and partly also from the greater regularity with which supplies of raw material were obtained from the northern powers. Indeed its progress has been quite astonishing; the imports of flax having risen from 3000 tons in 1814, to 15,000 tons in 1830. The exports of manufactured goods have increased in a corresponding ratio. During the year ending on the 31st of May 1831, there were imported into Dundee 15,010 tons of flax, and 3082 of hemp; and there were shipped off 366,817 pieces, being about 50,000,000 yards, of linen; 85,522 pieces, or about 3,500,000 yards, of sail-cloth; and about 4,000,000 yards of bagging; making a total of about 57,500,000 yards. In the year ending on the 31st of May 1833, the imports of flax amounted to 18,777 tons, besides 3380 tons of hemp. The shipments of linen, sail-cloth, and bagging, increased in a corresponding ratio, and were this year valued at L.1,600,000.

It appears, therefore, that the shipments of linen from this single port are as great as those from all Ireland; and whilst the manufacture has been tardily progressive in the latter, it has advanced in Dundee with even greater rapidity than the cotton manufacture at Manchester. It is not easy to account, in a satisfactory manner, for this wonderful advancement. Something must be ascribed to the convenient situation of the port for obtaining supplies of the raw material from the north of Europe; and more, perhaps, to the manufacture having been long established in the towns and villages of Strathmore, the Carse of Gowrie, and the northern parts of Fife, of which Dundee is the emporium. But these circumstances do not seem adequate to explain the pre-eminence which this place has recently attained in the linen manufacture; a superiority which must, we think, be ascribed, partly to a concurrence of fortunate accidents, and partly to the increased skill, enterprise, and capital of the manufacturers. From whatever causes this pre-eminence may have in the first instance arisen, it is obvious, however, that, having once been attained by any place like Dundee, it must be exceedingly difficult for others to come into competition with its manufacturers, who have on their side established connections, workmen of superior skill and dexterity, improved machinery, and constantly accumulating capital. Recently, indeed, the advantages possessed by old establishments have, to a considerable extent, been neutralised by the prevalence of combinations amongst the workmen; but it is to be hoped that means will speedily be devised for obviating this formidable, and, we fear, growing evil.

The following Table exhibits the quantity of British and Irish Linen Cloth, of all sorts, separately exported from England, Scotland, and Ireland, during the Year 1830; *specifying the quantities sent from each to the Countries importing the same, with their real or declared Values, and the Bounty paid on Exportation.*

[1] No British linen sent from Ireland.

[2] The declared value of the linens exported in 1831 was L.2,461,704.

There are no data sufficient to enable us to form an accurate estimate of the entire value of the linen manufacture of Great Britain. Colquhoun estimated it at L.15,000,000; but there cannot be a doubt that this is a great exaggeration. Sir F. M. Eden estimated the entire value of the linen manufacture of Great Britain, in 1800, at L.2,000,000; and if we assume that since that period the manufacture has been tripled in value, we shall not probably be far from the truth. Professor M'Culloch thinks that the entire produce of the manufacture in the united kingdom does not exceed L.7,500,000; but some very intelligent individuals, largely engaged in the trade, do not estimate it at so much; and, at all events, we may feel confident that this sum, if it err not in excess, is certainly by no means within the mark. If, then, we set aside a third part of this sum for the value of the raw material, and twenty-five per cent. for profits, wages of superintendence, wear and tear of fixed capital, coals, and other charges, there will remain L.3,125,000 to be divided as wages amongst those engaged in the manufacture; and, supposing every individual to earn at an average L.18 a year, the total number employed in it would be about 172,000. It may, perhaps, be thought that L.18 is too low an estimate for wages, and such would, no doubt, be the case, if Ireland were not taken into the average; but as a great many persons are there employed at very low wages, it may be inferred that L.18 is not very far from the mean rate, more especially as a vast number of persons in Ireland are only partly employed in the manufacture, whereas by this estimate it is supposed that 172,000 individuals are wholly employed in it.

It appears from official statements, which it is unnecessary to give in detail, that in 1830 the aggregate amount of the importations into the united kingdom, from various countries, of undressed hemp, flax, and tow or codilla, of hemp and flax dressed or undressed, and linen yarn, is, of the first, 506,771 cwt., of the second 944,096 cwt., and of the third, 19,211; the official value thereof being respectively, for Great Britain, L.411,832, L.1,923,428, and L.104,559, and for Ireland, L.15,926, L.18,803, and L.19,623. The official value of exports, ranged under the same heads, is, respectively, L.11,798, L.7720, and of linen yarn *nil;* so that the official value of hemp, flax, and linen yarn, left for consumption in the united kingdom, in 1830, was L.415,960, L.1,934,511, and L.124,182. From other accounts, it further appears that the consumption of foreign linens in this country is inconsiderable; in fact, the real or declared value of those entered for home consumption, in 1830, could scarcely exceed L.20,000.

The regulations as to the linen manufacture may be shortly stated. They are as follow: *1st,* Any person, native or foreigner, may, without paying any thing, set up in any place, privileged or not privileged, corporate or not corporate, any branch of the linen manufacture; and foreigners, practising the same, on taking the oath of allegiance, &c. become entitled to all the privileges of natural-born subjects. *2d,* Persons affixing stamps to foreign linens, in imitation of the stamps affixed to those of Scotland or Ireland, forfeit L.5 for each offence; and persons exposing to sale or packing up any foreign linens as the manufacture of Great Britain or Ireland, forfeit the same, besides L.5 for each piece of linen so exposed to sale or packed up. *3d,* Any person stealing, to the value of L.10, any linen, woollen, silk, or cotton goods, whilst exposed during any stage of the manufacture, in any building, field, or other place, shall, upon conviction, be liable, at the discretion of the court, to be transported beyond seas for life, or for any term not less than seven years, or to be imprisoned for any term not exceeding four years; and, if a male, to be once, twice, or thrice, publicly or privately whipped, as the court shall think fit. These regulations are founded on 15 Charles II. c. 15; 17 Geo. II. c. 30; and 7 and 8 Geo. IV. c. 49, § 14. (See M'Culloch's *Dictionary of Commerce,* art. LINEN.) (A.)

Fossil LINEN, is a kind of amianthus, which consists of soft, flexible, parallel fibres, and has been celebrated for the use to which it has been applied, of being woven, and forming an *incombustible cloth.* Paper and wicks for lamps have also been made of it.

LINGEN, a city of the province of Osnaburg, in the kingdom of Hanover, the capital of a bailiwick of the same name. It is situated on the river Ems, which is only navigable thereto for a few months in the year. It is surrounded with ditches, contains a Catholic, a Reformed, and a Lutheran church, 380 houses, and 1930 inhabitants. There is a seminary, sometimes called a university, with five professors. It has some manufactures of woollen goods. Long. 7. 12. 16. E. Lat. 52. 31. 41. N.

LINKOPING, a province in the south of Sweden, which extends in north latitude from 57. 41. to 59. 1., and in east longitude from 14. 26. to 17. 1., including 4510 square miles. It is a most picturesque country, covered with mountains, hills, lakes, rivers, and forests, but inhabited by only 165,000 inhabitants, in five cities or towns, and 5489 detached settlements. The chief employment is cutlery, sawing wood, and extracting some copper and iron from the mines. The capital is a city of the same name, situated on the Stang An, over which there is a well-constructed stone bridge. It is the seat of a bishop, and has a respectable cathedral, and two other churches; a gymnasium, with a good library and collections of natural history and medals; with 550 houses, and 2995 inhabitants, who carry on some trade in tanning and in linen weaving. Long. 15. 27. 48. E. Lat. 58. 22. 28. N.

LINLITHGOW, the capital of the county of that name, and once a place of some importance, is pleasantly situated on the bank of a fine lake, sixteen miles west from Edinburgh, and thirty-one east from Glasgow. It consists chiefly of a single street, running east and west along the south bank of the lake, containing many substantial though old houses; and is gradually improving in appearance, in consequence of the increasing number of modern buildings. The name Linlithgow is supposed by some to signify the *concavity of the Lin or Loch,* and according to others the lake of the sheltered valley. It is a very ancient town, having been the residence of royalty, and hence was entitled to be called a king's burgh in the twelfth century. It possesses an old palace or castle built by David I., which was destroyed by fire in 1745, and has not since been repaired. It has also a very ancient church, built in the Gothic style, ornamented with a spire of some height; and three dissenting meeting-houses. Though the town is very dull in appearance, the inhabitants are by no means inactive. The tanning of leather, for which the adjoining lake affords great convenience, is carried on to a considerable extent; as also the craft of shoemaking. Linen and woollen manufactures are pretty extensive, and there is a large calico-printing establishment about a mile from the town. It receives great advantage from the Union Canal, which passes in the immediate vicinity, for transporting goods to the capital. There is a weekly stock market held on Friday. The population in 1831 amounted to 4874.

LINLITHGOWSHIRE, or WEST-LOTHIAN, a county in Scotland, having the Frith of Forth on the north, Edinburghshire or Mid-Lothian on the east and south-east, Lanarkshire on the south-west, and Stirlingshire on the west, is situated between 55. 49. and 56. 1. north latitude, and 3. 18. and 3. 51. west longitude from Greenwich. It is of a triangular form, about nineteen miles long on its eastern boundary, and thirteen on its western; but at a medium it is only about seven miles broad and sixteen long, and its area is therefore 112 square miles, or 71,680 English acres; though, according to some surveys, the superficial contents of the whole is 121 square miles, or 77,440 statute acres.

So large a portion of the surface of this county is either level or gently undulating, that only a fifth part of it is stated to be unfit for cultivation. Yet a considerable space is occupied by hills. A ridge extends across it from north-west to south-east, of which Cairnpapple, the most elevated point, is about 1500 feet high. The highest ground is in the middle, and towards the west; on the south there is much moor and moss; but the hills for the most part yield good pasturage, and some of them are planted. The climate, though variable, is not severe. The prevailing winds are from the south-west, which blow for about two thirds of the year. According to a register of the weather, kept at Duddingston on the coast of the frith, about the middle of the northern boundary, the greatest number of rainy and snowy days, in any one year, for a period of thirty years, from 1778 to 1808, was 111 (in 1780), and the smallest number 22 (in 1803); but days on which slight showers fell are not included. The greatest heat in that period was in June 1785, when the thermometer stood at 87° in the shade, in a northern exposure. In June 1787, there was a week of frost, with ice one sixteenth of an inch in thickness.

Though there is a great variety of soil in this district, with considerable tracts of gravel and sand, yet clay is the most general. The coldest soil is chiefly on the south and south-western parts, which have also the coldest climate. The following estimate will show the quantity of the different kinds of soil found in the county:—Clay of good quality, 20,000 English acres; clay on cold bottom, 24,500; loam 10,000; light gravel and sand, 10,000; moors and high rocky land, 15,220; mosses, 1700; water, 500: total 81,920 English acres.

The only streams of any note are, the Almond, which rises on the border of Lanarkshire, and flows north-east for about twenty-four miles between this county and Edinburghshire; and the Avon, which forms the western boundary for about twelve miles. Both these rivulets fall into the Frith of Forth. On the north side of the town of Linlithgow there is a lake about a mile long and half a mile broad, occupying about 150 acres, which contains pike, perch, and eels; and a smaller one on the south, called Loch Coat, which occupies about twenty-two acres, stocked with the same kinds of fish. In the parishes of Linlithgow, Ecclesmachan, and Abercorn, there are several sulphureous springs; and a strong chalybeate is found in the parish of Torphichen; but none of them are much resorted to.

Silver and lead were at one time got in the hills of Bathgate, in the parish of Linlithgow; and in the neighbourhood a small vein of silver ore was found several years ago in a limestone quarry. Ironstone is wrought occasionally in the parishes of Borrowstownness and Carriden. Sandstone, in some places of an excellent quality, prevails along the coast of the Forth; and in the interior, whinstone, granite, and basalt, are also found; and there is an inexhaustible store of limestone. On Dundas Hill there is a basaltic rock 250 yards in length and about sixty feet in height, with an almost perpendicular front, consisting of a bluish granite of a very fine texture. There is also abundance of potters' clay, brick clay, red chalk, and marl. Shell marl was dragged in considerable quantities from the lake at Linlithgow, as a manure, till the benefits of lime superseded the use of it. But the chief mineral production is coal, which abounds in almost every part of the county, and is wrought in the parishes of Borrowstownness and Carriden on the Forth, in Uphall and Whitburn on the east and south, and in the parish of Bathgate in the middle. An excellent kind of coal has been wrought near Cultmuir, on the south-western border. The Union Canal, which passes through this county, affords excellent means of transporting the coal of the interior to the city of Edinburgh.

Linlithgowshire is for the most part divided into estates worth from L.200 to L.3000 a year; but there are a few above, and several below, these extremes. In the neighbourhood of the burghs of Linlithgow and Queensferry there are properties of only a few acres. Four of the greatest estates, rented at from L.4000 to L.10,000, belong to as many noblemen. The valued rent, taken in 1649, was L.75,027. 12s. 2d. Scots; in 1806, the real rent was L.64,518. 18s. 7d. sterling; and, in 1811, the real rent of the lands and mines was L.82,947. 2s., and of the houses, L.5798. 8s. Almost half the county is entailed. The principal seats are, Hopetoun House, Earl of Hopetoun, two miles west of Queensferry; Barnbougle Castle and Livingston House, Earl of Rosebery; Craigiehall, Mr Hope Vere; Duddingston, Mr Dundas; Hallyards, Mr Ramsay; Houston, Mr Sharp; Kinneil, Duke of Hamilton, near Borrowstownness; and Polkemmet, Mr Baillie.

The size of the farms is from fifty Scotch acres to 600, but the greater part consist of between 100 and 300 English acres. The rent of the better soils, which extend over half the county, varies from L.2 to more than L.5 the acre; that of the inferior clays is from 14s. to 20s., and of the high grounds from 6d. to 10d.; the average rent of the whole, in 1811, being rather more than 23s. the English acre. The common term of leases is nineteen or twenty-one years; but, in some instances, they are for twenty-four, thirty-eight, and even fifty-seven years: grazing farms are let on short leases, from one to four years. The crops raised are the same as in the other counties in this part of Scotland, which have already been described; and the general system of husbandry is not materially different, except that the dairy is more an object here than in the counties to the east and south-east. The county has two royal burghs, Linlithgow and Queensferry, and the towns of Bathgate and Borrowstownness; besides a number of thriving villages. It is divided into fourteen parishes, which, with two in Mid-Lothian, and four in Stirlingshire, form one presbytery. It sends one member to parliament, the constituency, according to the latest census, being 692. The annexed table contains an abstract of the population for 1811, 1821, and 1831.

YEARS.	HOUSES.			OCCUPATIONS.			PERSONS.		
	Inhabited.	By how many Families occupied.	Uninhabited.	Families chiefly employed in Agriculture.	Families chiefly employed in Trade, Manufactures, or Handicraft.	All other Families not comprised in the two preceding classes.	Males.	Females.	Total of Persons.

LINNÆUS, or LINNE, SIR CHARLES, a celebrated botanist and natural historian, was born on the 24th of May 1707, in a village called Roeshult, in Smaland, where his father, Nicholas Linné or Linnæus, was then vicar, but afterwards preferred to the curacy of Stenbrohult. It is said, that on the farm where Linnæus was born there yet stands a large lime tree, from which his ancestors took the surnames of *Tiliander*, *Lindelius*, and *Linnæus;* and that this origin of surnames, taken from natural objects, is not uncommon in Sweden.

This eminent man, whose talents enabled him to reform the whole science of natural history, acquired, early in life, some of the highest honours that await the most successful proficients in medical science. We find indeed that he was made professor of physic and botany in the university of Upsala at the age of thirty-four, and, six years afterwards, physician to Adolphus king of Sweden, who in the year 1753 still further honoured him, by creating him knight of the order of the polar star. Nor did his honours terminate here. In 1757 he was ennobled; and in 1776 the king of Sweden accepted the resignation of his office, and rewarded his declining years by doubling his pension, and by a liberal donation of landed property settled on him and his family.

It seems probable that Linnæus's taste for the study of nature was formed from the example of his father, who, as he has himself informed us, cultivated, as his first amusement, a garden plentifully stored with plants. Young Linnæus soon became acquainted with these, as well as with the indigenous plants of his neighbourhood. Yet, from the smallness of his father's income, the young naturalist was on the point of being destined to a mechanical employment: fortunately, however, this design was overruled. In 1717 he was sent to school at Wexio, where, as his opportunities were enlarged, his progress in all his favourite pursuits was proportionally extended. At this early period he paid attention to other branches of natural history, particularly to the study of entomology.

The first part of his academical education Linnæus received at Lund, in Sweden, under Professor Stobæus, who favoured his inclination for the study of natural history. After a residence of about a year, he removed in 1728 to Upsala. Here he soon contracted a close friendship with Artedi, a native of the province of Angermania, who had already been four years a student in that university, and, like himself, had a strong bent to the study of natural history in general, but particularly to that of ichthyology. Soon after his residence at Upsala, our author was likewise fortunate enough to obtain the favour of several gentlemen of established character in literature. He was in a particular manner encouraged in the pursuit of his studies by the patronage of Dr Olaus Celsius, at that time professor of divinity, and the restorer of natural history in Sweden; who, being struck with the diligence of Linnæus in describing the plants of the garden at Upsala, and his extensive knowledge of their names, not only patronized him in a general way, but admitted him to his house, his table, and his library. Under such encouragement, it is not strange that he made a rapid progress, both in his studies and the esteem of the professors; in fact, we have a very striking proof of his merit and attainments, since we find, that, after a residence of only two years, he was thought sufficiently qualified to give lectures occasionally from the botanic chair, in the room of Professor Rudbeck.

In the year 1731, the Royal Academy of Sciences at Upsala, having for some time meditated the design of improving the natural history of Sweden, at the instance particularly of Professors Celsius and Rudbeck, deputed Linnæus to make the tour of Lapland, with the view of exploring the natural history of that arctic region; an undertaking to which his reputation, already high as a naturalist, and the strength of his constitution, equally recommended him. He left Upsala on the 13th of May, and took his route to Gevalia or Gevels, the principal town of Gestricia, forty-five miles distant from Upsala. From thence he travelled through Helsingland into Medalpadia, where he made an excursion, and ascended a remarkable mountain before he reached Hudwickswald, the chief town of Helsingland. He then proceeded through Angermanland to Hernosand, a sea-port on the Bothnian Gulf, seventy miles distant from Hudwickswald. When he had advanced thus far, he found it proper to retard his journey, as the spring was not sufficiently advanced, and took this opportunity of visiting those remarkable caverns on the summit of Mount Skula, though at the hazard of his life.

When Linnæus arrived at Uma, in West Bothnia, about ninety-six miles from Hernosand, he quitted the public road, and took his course through the woods westward, in order first to traverse the most southern parts of Lapland. Having now reached the country that was more particularly the object of his inquiries, being equally a stranger to the language and to the manners of the people, and without any associate, he committed himself to the hospitality of the inhabitants, and never failed to experience it fully. He speaks in several places, with peculiar satisfaction, of the innocence and simplicity of their lives, and their freedom from diseases. In this excursion he reached the mountains towards Norway; and after encountering great hardships, returned into West Bothnia, quite exhausted with fatigue. He next visited Pitha and Lula, upon the Gulf of Bothnia; from which latter place he again took a western route, by proceeding up the river of that name, and visited the ruins of the temple of Jockmock in Lula Lapland or Lap Mark; he thence traversed what is called the *Lapland Desert*, destitute of all villages, cultivation, roads, or any conveniences, and inhabited only by a few straggling people, originally descended from the Finlanders, who settled in this country in remote ages, being entirely a distinct people from the Laplanders. In this district he ascended a noted mountain called Wallevari, in speaking of which he has given us a pleasant relation of his finding a singular and beautiful new plant (*Andromeda tetragona*), when travelling within the arctic circle, with the sun in his view at midnight, in search of a Lapland hut. From hence he crossed the Lapland Alps into Finmark, and traversed the shores of the North Sea as far as Sallero.

These journeys from Lula and Pitha on the Bothnian Gulf, to the north shore, were performed on foot; and he was attended by two Laplanders, one his interpreter, and the other his guide. He tells us that the vigour and strength of these two men, both old, and sufficiently loaded with his baggage, excited his admiration, since they appeared quite unfatigued by their labour, whilst he himself, although young and robust, was frequently quite exhausted. In this journey he was wont to sleep under the boat with which they forded the rivers, as a defence against rain, and the gnats, which in the Lapland summer are not less teasing than in the torrid zone. In descending one of these rivers, he narrowly escaped perishing by the oversetting of the boat, and lost many of the natural productions which he had collected.

Linnæus thus spent the greater part of the summer in examining this arctic region, and those mountains on which, four years afterwards, the French philosophers secured immortal fame to Sir Isaac Newton. At length, after having suffered incredible fatigues and hardships, in climbing precipices, passing rivers in miserable boats, suffering repeated vicissitudes of heat and cold, and not unfrequently hunger and thirst, he returned to Torneo in September. He did not take the same route from Torneo as when he set out for Lapland, having determined to visit and examine the country on the eastern side of the Bothnian Gulf. His first stage, therefore, was to Ula in East Bothnia, and thence to Old and New Carlebay, eighty-four miles south from Ula. He continued his route through Wasa, Christianstadt, and Biorneburg, to Abo, a small university in Finland. Winter was now setting in apace; he therefore crossed the gulf by the island of Aland, and arrived at Upsala in November, after having performed, mostly on foot, a journey of ten degrees of latitude in extent, exclusively of those deviations which such a design rendered necessary.

In 1733 he visited and examined the several mines in Sweden, and made himself so well acquainted with mineralogy and the docimastic art, that he was sufficiently qualified to give lectures on these subjects upon his return to the university. The outlines of his system of mineralogy appeared in the early editions of the *Systema Naturæ;* but he did not exemplify the whole until the year 1768.

In the year 1734 Linnæus was sent by Baron Reuterholm, governor of Dalecarlia, with several other naturalists in that province, to investigate the physical productions of that part of the Swedish dominions; and it was in this journey that he first laid the plan of an excellent institution, which was afterwards executed, in a certain degree at least, by himself, with the assistance of many of his pupils, and the result published under the title of *Pan Suecicus*, in the second volume of the *Amœnitates Academicæ.*

After the completion of this expedition, it appears that Linnæus resided for a time at Fahlun, the principal town in Dalecarlia, where he tells us that he taught mineralogy and the docimastic art, and practised physic; and where he was very hospitably treated by Dr More, the physician of the place. It also appears that he contracted at this time an intimacy with one of that gentleman's daughters, whom he married about five years afterwards, upon his settling as a physician at Stockholm. In this journey he extended his travels quite across the Dalecarlian Alps into Norway; but we have no particular account of his discoveries in that kingdom. In 1735 Linnæus travelled over many other parts of Sweden, some parts of Denmark and Germany, and fixed in Holland, where he chiefly resided until his return to Stockholm, about the year 1739. In 1735, the year in which he took the degree of doctor of physic, he published the first sketch of his *Systema Naturæ*, in a very compendious way, and in the form of tables, only in twelve pages in folio. By this it appears that he had at a very early period of his life, certainly before he was twenty-four years of age, laid the basis of that great structure which he afterwards raised, not only to the increase of his own fame, but to that of natural science.

In 1736 Linnæus arrived in England, and visited Dr Dillenius, the learned professor at Oxford, whom he justly considered as one of the first botanists in Europe. He mentions with particular respect the civilities he received from Dillenius, and the privileges he gave him of inspecting his own and the Sherardian collections of plants. It is needless to say, that he visited Dr Martyn, Mr Rand, and Mr Miller, and that he was in a more singular manner indebted to the friendship of Dr Isaac Lawson. He also contracted an intimate friendship with Mr Peter Collinson, which was reciprocally increased by a multitude of good offices, and continued to the last without any diminution. Dr Boerhaave had furnished him with letters to Sir Hans Sloane; but these, it seems, did not procure him the reception which the warmth of his recommendation appeared to claim.

One of the most agreeable circumstances that happened to Linnæus during his residence in Holland, arose from the patronage of Mr Clifford, in whose house he lived a considerable part of his time, being now as it were the child of fortune. *Exivi patriâ triginta sex nummis aureis dives*, are his own words. With Mr Clifford, however, he enjoyed pleasures and advantages scarcely at that time to be met with elsewhere in the world; that of a garden excellently stored with the finest exotics, and a library furnished with almost every botanic author of note. How happy he found himself in this situation, those only who have felt the same kind of ardour can conceive. Whilst in Holland, Linnæus was recommended by Boerhaave to fill the place, then vacant, of physician to the Dutch settlement at Surinam; but he declined it on account of his having been educated in so opposite a climate.

Besides being favoured with the particular patronage and friendship of Boerhaave and Mr Clifford, as has already been mentioned, he had also the pleasure of being contemporary with, and of reckoning amongst the number of his friends, many other learned persons who have since proved ornaments to their profession, and whose merit has most deservedly raised them to fame and honour. Amongst these may be mentioned Dr John Burmann, professor of botany at Amsterdam, whose name and family are well known in the republic of letters, and to whom our author dedicated his *Bibliotheca Botanica*, having been greatly assisted in compiling that work, by the free access he enjoyed to that gentleman's excellent library; John Frederick Gronovius of Leyden, editor of Clayton's *Flora Virginica*, and who very early adopted Linnæus's system; Baron Van Swieten, physician to the empress-queen; Isaac Lawson, afterwards one of the physicians to the British army, who died much regretted, at Oosterhout, in the year 1747, and from whom Linnæus received singular and most obliging civilities; Kramer, well known for an excellent treatise on the docimastic art; Van Royen, botanic professor at Leyden; and Lieberkun of Berlin, famous for his skill in microscopical instruments and experiments. To these may also be added the names of Albinus and Gaubius, and of others, were it requisite to show that our author's talents had very early rendered him conspicuous, and gained him the regard of all those who cultivated and patronized any branch of medical science; and to which, doubtless, the singular notice with which Boerhaave had honoured him did not a little contribute.

Early in the year 1738, after Linnæus had left Mr Clifford, and, as it should seem, when he resided with Van Royen, he had a long and dangerous attack of sickness; and upon his recovery went to Paris, where he was kindly entertained by the Jussieus, at that time the first botanists in France. The opportunity this gave him of inspecting the *Herbaria* of Royen and Tournefort, and those of the above-named gentlemen, afforded him great satisfaction. He had intended to proceed from thence into Germany, to visit Ludwig and Haller, with whom he was in close correspondence; but he was not able to complete this part of his intended route, and was obliged to return without this gratification.

Our author did not fail to avail himself of the advantages which access to the several museums of this country afforded him, in every branch of natural history; and the number and importance of his publications, during his absence from his native country, sufficiently demonstrate that fund of knowledge which he must have imbibed before, and no less testify his extraordinary application. These were, *Systematis Naturæ, Fundamenta Botanica, Bibliotheca Botanica*, and *Genera Plantarum;* the last of which is justly considered as the most valuable of all the works of this celebrated author. The immense application bestowed upon it the reader may easily conceive, when he is informed, that before the publication of the first edition the author had examined the characters of eight thousand flowers. The last book of Linnæus's composition, published during his stay in Holland, was the *Classes Plantarum*, which is a copious illustration of the second part of the *Fundamenta.*

About the latter end of the year 1738, or the beginning of the next, Linnæus settled as a physician at Stockholm, where he seems to have met with considerable opposition, and was oppressed by many difficulties; but all of these he at length overcame, and got into extensive practice; and, soon after his settlement, married the lady before mentioned. By the interest of Count Tessin, who was afterwards his great patron, and even procured medals to be struck in honour of him, he obtained the rank of physician to the fleet, and a stipend from the citizens for giving lectures in botany. And what at this time especially was highly favourable to the advancement of his character and fame, by giving him an opportunity of displaying his abilities, was the establishment of the Royal Academy of Sciences at Stockholm, of which Linnæus was constituted the first president, and to which the king granted several privileges, particularly that of free postage to all papers directed to the secretary. By the rules of the academy, the president held his place but three months. At the expiration of that term, Linnæus made his *Oratio de memorabilibus in Insectis*, on the 3d of October 1739; in which he endeavours to excite an attention and inquiry into the knowledge of insects, by displaying the many singular phenomena that occur in contemplating the nature of those animals, and by pointing out, in a variety of instances, their usefulness to mankind in particular, and to the economy of nature in general.

During all this time, however, Linnæus appears to have had his eye fixed upon the botanical and medical chair at Upsala, then occupied by Rudbeck, who was far advanced in life. We learn indeed that he was so intent on pursuing and perfecting his great designs in the advancement of his favourite study of nature, that he had determined, if he failed in procuring the professorship at Upsala, to accept the offer which had been made to him by Haller, of filling the botanic chair at Göttingen. However, in course of time, he obtained his wish. In the year 1741, upon the resignation of Roberg, he was constituted joint professor of physic, and physician to the king, with Rosen, who had been appointed in the preceding year on the death of Rudbeck. These two colleagues agreed to divide the medical departments between them; and their choice was confirmed by the university. Rosen took anatomy, physiology, pathology, and the therapeutic part; Linnæus, natural history, botany, materia medica, dietetics, and the diagnosis morborum.

During the interval of his removal from Stockholm to Upsala, in consequence of this appointment, our professor was deputed by the states of the kingdom to make a tour to the islands of Oeland and Gothland in the Baltic, attended by six of the pupils, commissioned to make such inquiries as might tend to improve agriculture and arts in the kingdom, to which the Swedish nation had for some time paid particular attention. The result of this journey was very successful, and having proved fully satisfactory to the states, was afterwards communicated to the public. On his return he entered upon the professorship, and on the 17th of October pronounced before the university his oration *de Peregrinationum intra Patriam necessitate*, in which he forcibly displays the usefulness of such excursions, by pointing out to the students that vast field of objects which their country held out to their cultivation, whether in geography, physics, mineralogy, botany, zoology, or economics, and by showing the benefit that must accrue to themselves and their country as rewards of their diligence. The animated spirit which pervades the whole of this composition renders it one of the most pleasing and instructive of all our author's productions.

Linnæus was now fixed in the situation which was the best adapted to his character, his taste, and abilities; and which seems to have been the object of his ambition and the centre of his hopes. Soon after his establishment, he laboured to get the academical garden, which had been founded in 1657, put upon a better footing, and very soon effected it, procuring also a house to be built for the residence of the professor. The whole had been in ruins ever since the fire in 1702; and at the time Linnæus was appointed professor of botany, the garden did not contain above fifty plants that were exotic. His correspondence with the first botanists in Europe soon supplied him with great variety. He received Indian plants from Jussieu of Paris, and from Van Royen of Leyden; European plants from Haller and Ludwig: American plants from Mr Collinson, Mr Catesby and others; and a variety of annuals from Dillenius; in short, how much the garden owed to his diligence and care in a few years, may be seen by the catalogue published under the title of *Hortus Upsaliensis, exhibens plantas exoticas horto Upsaliensis Academiæ a sese* (*Linnæo*) *illatas ab anno* 1742, *in annum* 1748, *additis differentiis synonymis, habitationibus, hospitiis, rariorumque descriptionibus, in gratiam studiosæ juventutis*, Holm. 1748, 8vo. By this catalogue it appears that the professor had introduced eleven hundred species, exclusively of all the Swedish plants and varieties, which, in ordinary gardens, amount not unfrequently to one third of the whole number. The preface contains a curious history of the climate at Upsala, and the progress of the seasons throughout the whole year.

From the time that Linnæus and Rosen were appointed professors at Upsala, it should seem that the credit of that university, as a school of physic, had been increasing: numbers of students resorted thither from Germany, attracted by the character of these two able men; and in Sweden itself many young men were invited to the study of physic by the excellent manner in which it was taught, who otherwise would have engaged in different pursuits.

Whilst Linnæus was meditating one of his capital performances, which had long been expected and greatly wished for, he was interrupted by a tedious and painful attack of the gout, which left him in a very weak and dispirited state; and, according to the intelligence which his friends gave of him, nothing was thought to have contributed more to the restoration of his spirits than the seasonable acquisition, at this juncture, of a collection of rare and undescribed plants.

The fame which our author had now acquired by his *Systema Naturæ*, of which a sixth edition, much enlarged, had been published at Stockholm in 1748, in 8vo, with eight tables explanatory of the classes and orders, had brought, as it were, a conflux of every thing rare and valuable in every branch of nature, from all parts of the globe, into Sweden. The king and queen of Sweden had their separate collections of rarities, the former at Ulricksdahl, and the latter, very rich in exotic insects and shells, procured at a great expense, at the palace of Drottningholm, both of which our author was employed in arranging and describing. Besides these, the museum of the Royal Academy of Upsala had been augmented by a considerable donation from the king, whilst hereditary prince, in 1746, by another from Count Gyllenborg the year before, and by a third from M. Grill, an opulent citizen of Stockholm.

From this time the professor appeared in a more elevated rank and situation in life. His reputation had already procured him honours from almost all the royal societies in Europe; and his own sovereign, sensible of his merit, and greatly esteeming his character and abilities, favoured him with a mark of his distinction and regard, by creating him a knight of the polar star. With science, it was no longer *laudatur et alget.* His emoluments kept pace with his fame and honours; his practice in his profession became lucrative; and we find him soon after possessed of a country-house and gardens at Hammarby, about five miles from Upsala. He had moreover received one of the most flattering testimonies of the extent and magnitude of his fame that perhaps was ever shown to any literary character, the state of the nation which conferred it, and all its circumstances, being duly considered. This was an invitation to Madrid from the king of Spain, there to preside as a naturalist, with the offer of an annual pension for life of two thousand pistoles, letters of nobility, and the perfect free exercise of his own religion. But, after the most perfect acknowledgments of the singular honour done him, he respectfully answered, "that if he had any merits, they were due to his own country."

In the year 1755, the Royal Academy of Sciences at Stockholm honoured our professor with one of the first premiums, agreeably to the will of Count Sparree, who had decreed two gold medals, of ten ducats value each, to be annually given by the academy to the authors of such papers, in the preceding year's Stockholm Acts, as should be adjudged most useful in promoting agriculture particularly, and all branches of rural economy. This medal bore on one side the arms of the count, with this motto, *Superstes in scientiis amor Frederici Sparree.* Linnæus obtained it in consequence of a paper *De plantis quæ Alpium Suecicarum indigenæ, magno rei œconomicæ et medicæ emolumento fieri possint;* and the ultimate intention was to recommend these plants as adapted to culture in Lapland. This paper was inserted in the Stockholm Acts for 1754 (vol. xv.). Linnæus also obtained the *præmium centum aureorum*, proposed by the Imperial Academy of Sciences at St Petersburg, for the best paper written to establish or disprove, by new arguments, the doctrine of the sexes of plants. It was, if possible, an additional glory to Linnæus to have merited this premium from the St Petersburg Academy, inasmuch as a professor of that society, a few years before, had with more than common zeal, although with a futility like that of the other antagonists of our author, endeavoured to overturn the whole Linnæan system of botany, by attempting to show that the doctrine of the sexes of plants had no foundation in nature, and was unsupported by facts and experiments.

It appears that Linnæus, upon the whole, enjoyed a good constitution; but that he was sometimes severely afflicted with a *hemicrania*, and was not exempted from the gout. About the close of 1776, he was seized with an apoplexy, which left him paralytic; and at the beginning of the year 1777, he suffered another attack, which very much impaired his mental powers. But the disease supposed to have been the more immediate cause of his death, was an ulceration of the urinary bladder, of which, after a tedious indisposition, he died, on the 11th of January 1778, in the seventy-first year of his age. His principal other works, besides those already mentioned, are, The *Iter Oëlandicum et Gotlandicum, Iter Scanicum, Flora Suecica, Fauna Suecica, Materia Medica, Philosophia Botanica, Genera Morborum,* different papers in the *Acta Upsaliensia*, and the *Amœnitates Academicæ.* The last of his treatises was the *Mantissa Altera*, published in 1771; but before his death he had finished the greater part of the *Mantissa Tertia*, afterwards completed and published by his son.

To the lovers of science it will not appear strange that uncommon respect was shown to the memory of this great man. We are told, "that on his death a general mourning took place at Upsala, and that his funeral procession was attended by the whole university, as well professors as students, and the pall supported by sixteen doctors of physic, all of whom had been his pupils." The king of Sweden, after the death of Linnæus, ordered a medal to be struck, one side of which exhibits Linnæus's bust and name, and the other Cybele, in a dejected attitude, holding in her left hand a key, and surrounded with animals and growing plants, with the legend, *Deam luctus angit amissi;* and beneath, *Post Obitum Upsaliæ, die x. Jan.* M.DCC.LXXVIII. *Rege jubente.* The same generous monarch not only honoured the Royal Academy of Sciences with his presence when Linnæus's commemoration was held at Stockholm, but, as a still higher tribute, in his speech from the throne to the assembly of the states, he lamented Sweden's loss by his death.

His stature was diminutive, being below the middle size; his head was large, and its hinder part very high; his look was ardent, piercing, and apt to daunt the beholder; his ear was not sensible to music; and his temper quick, but easily appeased. Nature had, in an eminent manner, been liberal in the endowment of his mind. He seems to have possessed a lively imagination, corrected by a strong judgment, a most retentive memory, unremitting industry, and the greatest perseverance in all his pursuits. This is evident from that continued vigour with which he prosecuted the design, which he appears to have formed so early in life, of totally reforming and constructing anew the whole science of natural history. And this fabric he raised, and gave to it a degree of perfection unknown before; and he had moreover the uncommon felicity of living to see his own structure rise above all others, notwithstanding every discouragement its author at first laboured under, and the opposition it afterwards met with. Neither has any writer more cautiously avoided the common error of building his own fame upon the ruin of another man's. He everywhere acknowledged the peculiar merits of each author's system; and no man appears to have been more sensible of the partial defects of his own. Those anomalies which had principally been the objects of criticism, he well knew that every artificial arrangement must abound with; and having laid it down as a fixed maxim, that every system must finally rest on its intrinsic merit, he willingly committed his own to the judgment of posterity. Perhaps there is no circumstance of Linnæus's life which shows him in a more dignified light than his conduct towards his opponents. Disdaining controversy, and justly considering it as an unimportant and fruitless sacrifice of time, he never replied to any assailant, numerous as they were at one season.

To all who observe the aid which this extraordinary man has brought to natural science, his talents must appear in a very conspicuous point of view; but more especially to those who, from similarity of tastes, are qualified to see more distinctly the vast extent of his original design, the greatness of his labour, and the elaborate execution he has given to the whole. He had a happy command of the Latin language, which alone is the language of science; and no man ever applied it more successfully to his purposes, or gave to description such copiousness, united with that precision and conciseness which so eminently characterize his writings.

The ardour of Linnæus for the study of nature, even from his earliest years, and that uncommon application which he bestowed upon it, gave him a most comprehensive view both of its pleasures and usefulness, at the same time that it opened to him a wide field, hitherto but little cultivated, especially in his own country. Hence he was early led to regret, that the study of natural history, as a public institution, had not made its way into the universities; in many of which, logical disputations and metaphysical theories had too long prevailed, to the exclusion of more useful science. Availing himself therefore of the advantages which he derived from a large share of eloquence, and an animated style, he never failed to display, in a lively and convincing manner, the relation which this study has to the public good; to incite the great to countenance and protect it; to encourage and allure youth into its pursuits, by opening its manifold sources of pleasure to their view, and showing them how greatly this agreeable employment would add, in a variety of instances, both to their comfort and emolument. His extensive view of natural history, as connected with almost all the arts of life, did not allow him to confine these motives and incitements to those only who were designed for the practice of physic. He also laboured to inspire the great and opulent with a taste for this study, and wished particularly that such as were devoted to an ecclesiastical life should possess some share of natural science; not only as a means of sweetening their rural situation, confined, as many are, perpetually to a country residence, but as that which would almost inevitably lead, in a variety of instances, to discoveries.

Linnæus lived to enjoy the fruit of his own labour. Natural history raised itself in Sweden, under his culture, to a state of perfection unknown elsewhere; and was from that time disseminated throughout all Europe. His pupils dispersed themselves all over the globe; and, with their master's fame, extended both science and their own. More than this, he lived to see the sovereigns of Europe found several public institutions in favour of this study; and even professorships established in different universities for the same purpose, chairs which do honour to their founders, and which have excited a curiosity for the science, and a sense of its worth, that cannot fail to advance its progress, and in time to raise it to that rank which it is entitled to hold amongst the pursuits of mankind.

LINOSA, an island in the Mediterranean Sea, belonging to the kingdom of Naples. It is about six miles in circumference, and entirely volcanic, with an extinct crater in its eastern side, and three others, smaller, but distinctly marked, in other parts. It is uninhabited. Long. 12. 52. 9. E. Lat. 35. 51. 50. N.

LINT. See Flax and Linen.

Lint, in *Surgery*, is the scrapings of fine linen, used by surgeons in dressing wounds. It is made into various forms, which acquire different names according to the difference of the figures. Lint made up in an oval or orbicular form is called a *pledgit;* if in a cylindrical form, or in the shape of a date, or olive-stone, it is called a *dossil.*

LINTON, a market-town of Cambridgeshire, in the hundred of Chilford, forty-six miles from London, and ten from Cambridge. The ancient Roman road, the Ikeneld Street, runs to this town, and the river Granta flows at the end of it. The market day is Thursday. The population amounted in 1801 to 1157, in 1811 to 1373, in 1821 to 1519, and in 1831 to 1678.

LINTSTOCK, in military affairs, a wooden staff about three feet long, having a sharp point in one end, and a sort of fork or crotch on the other; the latter serving to contain a lighted match, whilst by the former the lintstock is occasionally stuck in the ground, or in the deck of a ship during an engagement. It is frequently used in small vessels, where there is commonly one fixed between every two guns, by which the match is always kept dry, and ready for firing.

LINZ, a city of Austria, in the circle of Muhlviertel, and province of Upper Ens. It is the capital of the province and the circle, and stands on the right bank of the Danube. It is a well-built city, with three suburbs, a fine market-place, and a castle upon a hill which overlooks it. It contains three churches, three monasteries, and two nunneries, 1280 houses, and 18,500 inhabitants. There is an academical institution, with eighteen professors, directing studies in divinity, law, philosophy, surgery, and medicine, and a library of 22,000 volumes. It is a place of manufacturing industry, producing good woollen cloths, cassimeres, and carpets, as well as some cotton goods and hosiery. It carries on considerable trade by the Danube, both upwards and downwards, and has two fairs annually, which continue fourteen days. Long. 14. 11. 25. E. Lat. 48. 18. 54. N.

Linz, a city, the capital of the circle of the same name, in the Prussian government of Coblentz. It is situated on the river Rhine, and contains 380 houses, with 1980 inhabitants, who grow some wine, and carry on fisheries, and also navigation on the river. Near it are some iron-works.

LINUS, in classical history, a native of Colchis, who was contemporary with Orpheus, and one of the most ancient poets and musicians of Greece. It is impossible, at this distance of time, to discover whether Linus was the disciple of Orpheus, or Orpheus of Linus. The majority, however, seem to decide this question in favour of Linus. According to Archbishop Usher, he flourished about 1280 B. C. and is mentioned by Eusebius amongst the poets who wrote before the time of Moses. Diodorus Siculus tells us, on the authority of Dionysius of Mitylene the historian, who was contemporary with Cicero, that Linus was the first amongst the Greeks who invented verses and music, as Cadmus first taught them the use of letters. The same writer likewise attributes to him an account of the exploits of the first Bacchus, and a treatise upon Greek mythology, written in Pelasgic characters, which were also those used by Orpheus, and by Pronapides the preceptor of Homer. Diodorus says that he added the string called *lichanos* to the Mercurian lyre, and ascribes to him the invention of rhythm and melody, which Suidas, who regards him as the most ancient of lyric poets, confirms. Marpurg conceives that Linus invented catgut strings for the use of the lyre, which, before his time, was only strung with thongs of leather, or with different threads of wax strung together. He is said by many writers to have had several disciples of great renown; amongst whom were Hercules, Thamyris, and, according to some, Orpheus. Hercules, says Diodorus, in learning from Linus to play upon the lyre, being extremely dull and obstinate, provoked his master to strike him; which so enraged the young hero, that instantly seizing the lyre, he beat out the brains of the musician with his own instrument.

LIONCELLES, in *Heraldry*, a term used for several lions borne in the same coat of arms.

LIOTARD, called the *Turk*, an eminent painter, was born at Geneva in 1702, and was intended by his father to be a merchant; but, by the persuasion of his friends, who observed the genius of the young man, he was permitted to give himself up to the art of painting. He went to Paris in 1725, and in 1738 accompanied to Rome the Marquis de Puisieux, who was going as ambassador to Naples. At Rome he was taken notice of by the Earls of Sandwich and Besborough, who engaged Liotard to attend them in a voyage to Constantinople. There he became acquainted with Lord Edgecumbe, and with Sir Everard Fawkener, our ambassador, who persuaded him to proceed to England, where he staid two years. In his journey to the Levant he had adopted the eastern habit, and wore it here with a very long beard. It contributed much to the portraits which he drew of himself, and, some thought, to draw customers; but he was really a painter of uncommon merit. After his return to the Continent, he married a young wife, and sacrificed his beard to Hymen. He came again to England in 1772, and brought a collection of pictures of different masters, which he sold by auction, and some pieces of glass painted by himself, with surprising effect of light and shade, but which were a mere curiosity, as it was necessary to darken the room before they could be seen to advantage. He remained here about two years, as in his former journey. He has engraved some Turkish portraits, one of the empress queen, and the eldest archduchess, in Turkish habits, besides the heads of the emperor and empress. He painted well in miniature, and also in enamel, though he seldom practised it. But he is best known by his works in crayons. His likenesses were as exact as possible, sometimes too like to please those who sat to him. Being devoid of imagination, he could render nothing but what he saw before his eyes. Freckles, marks of the small-pox, every thing found its place; not so much from fidelity, as because he could not conceive the absence of any thing that appeared to him. Truth prevailed in all his works, grace in few or none. Nor was there any ease in his outline; the stiffness of a bust prevailed in all his portraits.

LIPARI, the collective name of a group of islands in the Mediterranean Sea, forming a part of the kingdom of Naples. They were known in the most remote ages as the Ephestiades, in the subsequent centuries as the Æolian Islands, and latterly have commonly borne the name of the most considerable of their number. According to the mythology of the heathens, they were imagined to be the chimneys of a vast subterraneous cavity, inhabited by Steropes, Brontes, and Argos; and the caverns in which Æolus confined the winds were in this archipelago. Here Diana was said to have been placed by Latona in her infancy, and here also Vulcan forged the thunderbolts of Jupiter.

It is most probable that, at an early period, Liparus, the son of Auson, having passed from Italy with some of his followers, planted the largest of the islands, and conferred his name upon it. Æolus, the son of Hippotas, arrived afterwards, and marrying Cyane, the daughter of Liparus, succeeded to the throne; and being very attentive to meteorology, and often successfully predicting changes of weather, this may have given rise to the fabulous power attributed to him. This colony had suffered a decline, in spite of an augmentation of the inhabitants by the immigration of some Rhodians and Cnidians, when it was visited by some Etruscan pirates, who built the city of Lipari, and, by means of husbandmen transported from the continent, extended cultivation to the other islands. Since that period, they have been subject to Sicily, forming in Christian times a bishopric, restricted in 1394 to these islands. The whole of these islands exhibit the corrosive effects of gases and spray; but their western coasts, rising abruptly in precipitous masses, and shelving down gradually to the eastward, form an interesting geological feature, in which it agrees with the greater part of the West India and other islands. It is remarkable that, besides the western coasts of all these islands being steep and craggy, they have each of them a high isolated rock on their northern shores. The basis of the whole group is hornstone, with the various alterations and decompositions occasioned by volcanic influence; an influence easily traceable throughout these islands, in its grandest and wildest varieties.

The climate is highly salubrious, and the weather generally soft and refreshing; but though there are a few trifling springs, a general scarcity of water is experienced, as the soil, consisting almost entirely of scoriæ, tuffa, pumice, pozzolana, and ashes, without any intervening stony stratum, except occasional masses of obdurate vitrification, rapidly absorbs the moisture. The natives are consequently obliged to construct capacious cisterns, in which rain-water is preserved in a cool temperature. Most of the cattle are lean, and they are not abundant, as the pasturage is only adapted for the most part to the feeding of goats. The land is well cultivated, and yields grapes, currants, figs, prickly pears, corn, cotton, olives, and pulse, which latter grow under the cane trellises that support the vines. Violent rains sometimes cause great injury to the grounds, owing to their situation, and the friability of the soil; and at other times swarms of locusts greatly injure and diminish the produce. A large quantity of wine and currants is annually exported, and an active trade is carried on in bitumen, pumice, nitre, pozzolana, cinnabar, coral, and fish. At one period alum formed a considerable article of export, but it has decreased, probably owing to the diminished heat of the subterranean fires. Some sulphur is still shipped, but in less quantity than formerly, owing to a prejudice entertained by the inhabitants, that the vapour which arises from purifying it infects the air, and is injurious to vegetation.

The inhabitants, who amount in all these islands to 22,350, are contented, temperate, and hardy, and are esteemed excellent sailors; but they are commonly considered as impertinent, mean, and immoral. They are by no means rich, but few are in extreme poverty; and, from leading an active life, they are healthy, except that, from their filthy habits, the itch is very prevalent amongst all classes. They are described as very expert slingers and throwers of stones, a valuable talent in an unarmed population, exposed to predatory visits from corsairs. The islands are variously enumerated, some stating them to be eight or nine, and others eleven. This has arisen from those who stated them at the greater numbers including some which are uninhabited, or may be considered as mere rocks belonging to adjacent islands.

1*st*, The island of Lipari is the largest and most populous of the whole group. It is accessible by a bay on the east side of the island, formed on the north by Monte Rosso, an immense mass of volcanic matter, and on the south by Cape Capistello, a rugged rock of lava. It is hilly, but intermixed with peculiarly beautiful and fertile valleys and plains, from which, amongst other produce, is supplied the Malmsey wine, whose flavour is admired in most parts of the world. The extent of the island is 110 square miles, and the population amounts to about 15,000 persons. Lipari has not suffered from volcanic eruptions for many ages, but its subterraneous fires are not yet extinguished; for, on digging in the central parts of the island to a trifling depth, heat, smoke, and a sulphureous smell, immediately arise. The highest mountain, St Angelo, contains a crater 200 feet wide; and on another mountain, Guardia, the course of the lava from an eruption is still visible. Lipari is literally the wreck of a vast conflagration, and affords perhaps the finest field in the world for the study of the geologist. This island contains the capital, the seat of government of the whole group. It is a city of the same name, situated on the south-east side; it has two havens, is the see of a bishop, and has a castle, a cathedral, and several other churches. It is healthy, though crowded, irregular, and filthy. It contains 12,500 inhabitants. Long. 14. 57. 50. E. Lat. 38. 27. 56. N.

2*d*, Volcano is a lofty island, fifteen miles in circuit, and possesses two small ports on the northern side. At a small distance from these ports is a hill, having a great crater, with a deep valley encircling, and detaching it from the neighbouring hills. It is about 2400 feet in height, but accessible to the summit with no little fatigue and some danger. The crater is a mile and a quarter in circumference, and nearly a quarter of a mile deep, forming an inverted elliptical cone, with the northern considerably higher and hotter than the southern side. The interior is full of volcanic scoriæ, coated over with sulphur, alum, vitriol, and muriate of ammonia, diverging into every possible shade of brown, red, green, blue, orange, black, yellow, and white. From the numerous apertures in every part, a sulphureous and hydrogenous vapour rushes out in gusts, which, when collected on the sides, where a considerable quantity of sulphur has been deposited by sublimation, forms a species of stalactite, covered with boracic or other light efflorescences. The bottom is about two or three hundred yards in extent. There is a frequent explosion of gases, and a continued roar similar to that of a cataract, or of many anchor-smiths' forges, which impress on the imagination the horrid feeling of being only separated by a frail crust from some vast abyss of central fire. Fire is only observable at night, when a pale lambent flame is seen to issue from many of the fissures, accompanied with nauseous fumes and vapours. There are but few inhabitants, and these are mostly employed in the sulphur works. Long. 14. 57. 50. E. Lat. 38. 27. 56. N.

3*d*, Salina. This island is to the north-west of Lipari, and is about fourteen miles in circumference, with an industrious population of 4000 persons, employed in raising grain, fruit, pulse, capers, salt, alum, and soda. Although no mention is made in history of any eruption, it is evidently of volcanic origin, and there are palpable vestiges of its once desolating craters, the fires of which must have ceased before the dawn of history, whilst they have now become the most pleasing and fertile spots of the group of islands. Long. 14. 55. 56. E. Lat. 38. 35. 40. N.

4*th*, Felicudi. This island is ten miles to the westward of Salina, is nine miles in circumference, and contains about 1100 inhabitants. The soil consists chiefly of detached masses of ferruginous and argillaceous lava, strongly marked with white felspars and black schorl, intermixed with enamel, cinders, sand, and pozzolana. It is highly fertile, and produces wheat, barley, grapes, olives, pulse, and flax, in abundance. It is an extinct volcano, with three high mountains; but there are no remains of the fire that produced the island, nor does history give any accounts of eruptions. Long. 14. 29. 37. E. Lat. 38. 34. 5. N.

5*th*, Alicudi. This is the westernmost of the islands, and rises like a cone from the sea, having a crater, the fires of which have been extinct for ages; but the lava is seen in grotesque streams, extending from the summit to the sea. The few spots capable of cultivation are highly fertile, and support 750 inhabitants. Long. 14. 16. 30. E. Lat. 38. 32. 41. N.

6*th*, Panaria, a small island to the north of Lipari, is seven miles in circumference, has a good port, and about two hundred inhabitants, who, from a rich soil, produce corn, wine, soda, and especially excellent raisins. The rocks around it, called the Dattoli, appear to have formed the circumference of an immense crater. It was known by the Romans as *Thermissea*, and was celebrated for its warm baths. Long. 15. 2. 55. E. Lat. 38. 37. 40. N.

7*th*, Basiluzzo, a small island to the north of Panaria, is about a mile and three quarters in circumference, and is very thinly inhabited. It produces corn, flax, and culinary vegetables, and is overrun with rabbits, which injure the crops. Like the rest of the group, this island exhibits abundant proofs of its volcanic origin. Long. 15. 7. 54. E. Lat. 38. 39. 50. N.

8*th*, Stromboli, the most northern of this group of islands, was known to the ancients by the name of *Strongyle*. It is a conical mountain, with an irregular base. It is upwards of 2000 feet high, is bifurcated, and about nine miles in circumference; and, from every indication, seems an evident product of subterranean fire. The crater has been rarely visited, on account of the great difficulty of ascending to it. The best description is that of Captain William Henry Smyth, who surveyed the whole of these islands, as well as the shores of the Mediterranean. About one third of the way from the summit of the mountain the crater appears. It is continually burning, with frequent explosions, and a constant ejection of fiery matter. It is of a circular form, about one hundred and seventy yards in diameter, with a yellow efflorescence adhering to its sides like that of Ætna. When the smoke clears away, an undulating igneous substance is to be seen, which at short intervals rises and falls with great agitation, and, when swollen to the utmost height, bursts with a violent explosion and a discharge of red-hot stones in a semi-fluid state, accompanied with showers of ashes and sand, and a strong sulphureous smell. The masses are usually thrown up to the height of from sixty or seventy to three hundred feet; but some, the descent of which Captain Smyth found to occupy from nine to twelve seconds, must have ascended above a thousand. In the moderate ejections, the stones in their ascent gradually diverge like a pyrotechnical exhibition, and fall into the abyss again, except on the side next the sea, where they roll down in quick succession, after bounding from the declivity, to a considerable distance in the water. This crater, which is on the north-west side of the mountain, has burned without intermission from the earliest periods. The incessant combustion is supposed to be kept up by oxygen, pyrites, and sulphur; but there are no traces of the presence of bitumen. It appears to be not only the vent of all these islands, but to have a subterraneous communication with Sicily and Italy; for, previous to a severe earthquake taking place in those parts, Stromboli has been observed to be covered with dense clouds of smoke, and to emit, with increased activity, unusually ardent flames. It appears, moreover, from the concurrent relation of the islanders, to be influenced by atmospheric changes, as storms, particularly those from the southward, which are preceded by thick volumes of smoke, so that the native pilots are guided at night by its flame, and gain intimation of the weather by day from the smoke.

The island contains about 1200 inhabitants, who have neither magistrate nor lawyer, but are governed by two priests. The soil is a fertile black mould, producing wine, wheat, barley, cotton, raisins, currants, and figs. There is an extinct volcano on Mount Schicceola, which burned in the time of Aristotle, and was noticed by him. The church is dedicated to St Bartholomew, and is in long. 15. 13. 10. E. and lat. 38. 48. 12. N.

LIPES, a province of Bolivia, or Upper Peru, in the department of Potosi, about sixty leagues long from north-west to south-east, and twenty in breadth. It was formerly a place of great wealth, possessing a considerable number of valuable mines; but many of them have been abandoned on account of the breaking in of water. It has still two mines of gold, one of silver, and one of copper; together with mines of red and white copper, the strata of which are intermixed with gold, silver, iron, and loadstone. The climate is generally cold, and the land unfruitful; but there are particular parts where it is good, and vegetation considerable. Cattle are found in great abundance, inhabiting that part of the chain of the Andes which intersects the province. There are also great numbers of birds.

LIPES, the capital of the above province, was formerly a large and populous town, but has gradually decayed in importance with the province. It is now a small and miserable place. Long. 68. 16. W. Lat. 21. 40. S. The population of the district and town is estimated at about 20,000.

LIPEZK, a circle in the Russian province of Tambow, extending from north latitude 52. 6. to 52. 4., and from east longitude 39. 18. to 40. 32., and containing 1208 square miles. It consists of an extended plane, which includes some steppes, and is more abundant in corn than in wood. It is watered by the rivers Woronesh and Worona. The capital is the city of the same name situated on the Woronesh, 760 miles from St Petersburg, containing 1015 houses and 6440 inhabitants. Long. 39. 45. E. Lat. 52. 50. N.

LIPPA, a fortified town of the circle of Arad, in the province of Farther Theiss, in Hungary. It stands on the river Maros, has a Catholic and a Greek church, and is the seat of a protopope. It contains 390 houses, and 2530 inhabitants, who make much culinary salt, and grow good corn and wine. Long. 21. 35. 7. E. Lat. 46. 5. 9. N.

LIPPE, the capital of a county of the same name in the circle of Westphalia, in Germany. It is situated on a river of the same name, and was formerly the residence of the principal branch of the house of Lippe. It is now in the possession of the king of Prussia, and carries on a good trade in preparing timber for building vessels on the Rhine, with which it has a communication by the river Lippe. The country round it is unwholesome and marshy. Long. 8. 12. E. Lat. 51. 43. N.

LIPPE-DETMOLD, a principality in the north-west of Germany. It is bounded on the north by the Prussian Westphalian province, on the north-east by Schauenburg, on the east by Hanover and Waldeck, and on the south-east, south, and west by the Prussian provinces. It is 453 square miles in extent, and comprehends six walled towns, five market-towns, and 145 villages, with 71,450 inhabitants. It is a hilly and woody district, between the Rhine and the Weser. On the slope of the hills there is some good wheat and rye land, but the whole principality produces barely corn sufficient for the consumption, and the cultivation of potatoes has been of late years extended in a degree commensurate with the increase of the population. The only articles for exportation furnished by the state are wood, which passes down the Weser to Bremen; flax and linen yarn, which is sold to the makers of linen in Lemgo, Bielfield, and other parts of Westphalia; and wool, which passes by Bremen to England or Holland. There are no mines, but there is a saline spring at Salzuflen, from which 35,000 bushels of culinary salt are prepared. The income of the state is about L.48,000 yearly, of which L.30,000 is derived from the princely domains and royalties. There was a national debt till lately, but it is nearly discharged by a sinking fund. The military force consists of a battalion of infantry, containing 300 men; besides which there is a militia, in which every man is liable to serve. The principality is divided into twelve bailiwicks. The capital is the city of Detmold, containing 2500 inhabitants.

LIPPI, Lorenzo, an historical and portrait painter, was born in 1606, and learned the principles of painting from Matteo Roselli. He had a fine genius for music and poetry, as well as for painting; and in the latter his proficiency was so great, that some of his compositions in the historical style were taken for those of Roselli. But becoming dissatisfied with the manner of that master, he chose that of Santi di Titi, who was excellent both in design and invention, and appeared to have more of simple nature and truth in his compositions than any other artist of that time. At Florence Lippi painted many excellent designs for the chapels and convents, by which he extended his reputation; and at the court of Innspruck he painted a great number of portraits of the first nobility, which were deservedly admired. Yet, although he was fond of imitating simple nature without any embellishments of invention, his works are held in the highest esteem for the graceful airs of the heads, the correctness of his outline, and the elegant disposition of the figures. He died in 1664.

LIPPSTADT, a city, the capital of a circle of the same name in the Westphalian Prussian government of Arensburg. It stands on the river Lippe, and contains 575 houses and 3290 inhabitants. There are in it one Catholic, one Calvinist, and four Lutheran churches. One half of the city belongs to the prince of Lippe-Detmold, but the garrison consists of Prussians, and the officers of that monarch regulate the affairs of the post. There is some trade in linen and woollen goods, and in making oil, soap, vinegar, and corn spirits. Long. 7. 45. 55. E. Lat. 51. 38. 59. N.

LIPSIUS, Justus, a critic and antiquary of high reputation, was born on the 18th of October 1547, at the village of Isque, situate at an equal distance from Brussels and Louvain. His father, Gilles Lipse, a native of Brussels, belonged to one of the best families of that city, and inherited considerable property, which he impaired by his improvident mode of life. The name of his mother was Isabelle Petirive. At the age of six he removed to Brussels along with his parents; and being then sent to school, he discovered great aptitude for acquiring the elements of learning. Having reached his tenth year, he was placed at Ath in Hainaut, where he was initiated in Latin grammar; and after another interval of two years, he became a student in the college of the Jesuits at Cologne. There he devoted himself to the study of the Greek language, and likewise of history and philosophy. It was the policy of the Jesuits to allure into their society such of their pupils as exhibited the greatest promise of talent; and this young scholar was nearly entangled in their net, when his parents, having heard of his desire to enrol himself in the fraternity, recalled him from Cologne, and sent him to the university of Louvain. He had then attained the age of seventeen, and had already begun to exhibit various indications of his future eminence in letters. His father had destined him for the legal profession, and, that he might seem to comply with his wishes, the son bestowed some attention upon the study of jurisprudence; but philology and philosophy were his favourite pursuits, and of his proficiency in philology he exhibited a very early and conspicuous specimen. The death of his father, when he himself had nearly completed the eighteenth year of his age, left him at full liberty to devote himself to such studies as best suited his own inclination. After this event, his mother fixed her residence at Louvain, bringing with her an only daughter: she made a strenuous effort to preserve the remnant of their fortune, but her worldly cares were soon terminated by a dropsy. In the year 1567, before he had completed the age of twenty, he published his "Variarum Lectionum libri tres," which he dedicated to Cardinal de Granvelle, and which procured him no mean reputation as a critic. It likewise had the effect of recommending him to the favour of this dignitary; who on proceeding to Rome for the purpose of assisting at the election of a pope, was accompanied by Lipsius in the capacity of his Latin secretary.

Here he had an opportunity of attending the prelections of Muretus, who was at that time a professor in the university of Rome; and with this very elegant scholar he appears to have contracted some degree of intimacy. He likewise became acquainted with several other learned men who then resided in Italy. His leisure hours were chiefly devoted to the examination of manuscripts preserved in the Vatican and other libraries; nor did he neglect those monuments of antiquity which, in so many different forms, solicited the notice of a young and ardent scholar. In the service of the cardinal he continued nearly two years; and having then returned to Louvain, and being released from all his engagements, as well as from all restraint, he there spent another year with little improvement of his learning or morals. But he at length became sensible of the folly of a life wasted in the frivolous and unsatisfactory pursuit of pleasure; and in order to effect a complete interruption of his habits and associations, he adopted the prudent resolution of again travelling in foreign countries. On passing through Franche Comté, he directed his course to Dole, the seat of a university, and there pronounced a panegyric on his friend Victor Giselin, on the occasion of his taking a doctor's degree in physic. To the banquet which followed this ceremony he did so much honour, that he was seized with a fever which endangered his life. On regaining sufficient strength, he pursued his journey to Vienna, and there became acquainted with Busbequius, Sambucus, Pighius, and other men of learning. Such was the impression of his talents and attainments, that he was solicited to remain in the Austrian dominions; but he declined more than one offer of employment, and adhered to the resolution of returning to his native country. Proceeding to Bohemia, he visited Prague, and was travelling through Germany, when he received an alarming account of the progress of the war in the Netherlands, and the serious injury to which his own property had been exposed. In this situation of his affairs, he was glad to accept the professorship of history and eloquence in the university of Jena. To this office he was admitted in the year 1572, and he retained it till the first of May 1574, when some indications of a favourable change had encouraged him to think of revisiting his native soil. But he first directed his course towards Cologne, where he married a widow named Anne Calstrie, who was descended of a good family at Louvain, and by whom he had no children. His first edition of Tacitus was printed in octavo, at Antwerp, in the year 1574. To the illustration of this favourite author he afterwards devoted much labour; and a sixth edition, in folio and quarto, was printed at the same place in 1600. His "Antiquarum Lectionum libri quinque" were printed at Antwerp in 1575.

Having lingered nine months at Cologne, he conducted his wife to Isque, where he hoped to lead a life of studious tranquillity; but his dreams of felicity were speedily dispelled by the renewal of hostilities in that vicinity, and he found it expedient to seek shelter at Louvain. At the suggestion of his friends, he resumed the study of jurisprudence, and in the year 1576 he took the degree of LL. D. His taste and inclination did not lead him to the practice of this profession; but his knowledge of the civil law was of material use in the illustration of Roman antiquities. In 1577 he published his "Epistolicarum Quæstionum libri quinque; in quîs ad varios Scriptores, pleræque ad T. Livium, Notæ." Here he could not long pursue his studies without alarm and danger: the war continuing with unabated vigour, Louvain was exposed to a siege, and changed its masters. After this event, he was offered the professorship of history in the university of Leyden; to which he accordingly removed in the year 1579, and there taught with high reputation. At Louvain he was a papist, at Jena he had been a Lutheran, and at Leyden he now became a Calvinist; if any adequate preferment had allured him to Constantinople, he would in all probability have become a Mohammedan. Towards the close of his life, Lipsius denied that he had ever conformed to the established church of Holland; but if any regard is due to this denial, how are we to understand the positive declaration of his zealous biographer Le Mire, who has stated that after his retreat from Leyden, he was publicly reconciled to the church of Rome? If he had never forsaken its communion, where was the necessity or the pretext for such a reconciliation? Niceron admits that he long appeared to be very indifferent about religion, and that it was his great principle to conform to the religion of the place where he resided; but, subjoins the reverend father, he at length quitted this state of indifference, and was constantly and sincerely attached to the Catholic faith, in which he was born.[1] Of the sincerity of a man who had so long adhered to this great principle, that is, who had so long evinced a total want of principle, it would seem but reasonable to require some very substantial evidence. During the latter years of his life, he certainly adhered to the tenets of popery, and endeavoured to signalize his zeal by professing to merge his intellect in the most abject superstition: but this was perhaps the mere zeal of a convert making his third profession, and fully aware of the extreme suspicion which his previous conduct could not have failed to excite; and had the course of his fortunes finally conducted him from Louvain to Oxford, it is by no means a violent or uncharitable supposition that he might have closed his career in the odour of high-church sanctity.

At Leyden he produced several of his more elaborate works. In 1580 appeared "Electorum liber primus," and in 1582 "Electorum libri duo; in quibus, præter Censuras, varii prisci Ritus;" in 1584 "De Amphitheatro liber; in quo Forma ipsa Loci expressa, et ratio spectandi;" to which is subjoined "De Amphitheatris quæ extra Romam libellus;" and in 1585 "Saturnalium Sermonum libri duo, qui de Gladiatoribus." In 1586 he published "De recta Pronuntiatione Latinæ Linguæ Dialogus;" of which dialogue the scene is laid in Rome, and the interlocutors are Lipsius and Muretus. It is dedicated to Sir Philip Sidney. His edition of the tragedies ascribed to Seneca was printed in 1588. Nor were his enquiries confined to philology and antiquities. In 1584 he had published "De Constantia libri duo, qui Alloquium præcipue continent in publicis Malis;" and in 1589 he produced a more ample work entitled "Politicorum, sive Civilis Doctrinæ, libri sex, qui ad Principatum maxime spectant." The publication of this work was attended with some unpleasant consequences to the author, and it served to evince that his wisdom was not equal to his learning. He recommends, in very plain terms, the punishment of heretics, or, in other words, of those who dissent from the established faith; nor can it escape the observation of the most obtuse reader that this recommendation proceeded from a man who, according to his own doctrine, ought to have been punished at Jena if he had adhered to the opinions which he professed at Louvain, who ought to have been punished at Leyden if he had adhered to the opinions which he professed at Jena. But it must be admitted that his conduct was perfectly consistent in one respect, inasmuch as he changed his religion as often as he changed his place of residence. Wherever his lot was cast, he was never to be found among the nonconformists. This doctrine of exterminating heresy by fire and sword, proceeded with a peculiar grace from an individual who, having escaped from the wreck of his fortunes, had been protected and cherished by a people so recently released from the iron yoke of Spain, with all the atrocities of the Spanish inquisition. His intolerant opinions were immediately attacked by Theodore Koornhert; and finding himself placed in a situation of no small embarrassment, he, in 1590, made a very abortive attempt to defend himself, in a work entitled "De una Religione adversus Dialogistam liber; in quo tria capita libri quarti Politicorum explicantur." His antagonist prepared a reply, which was not printed till after the death of the author.[2] In consequence of these illiberal and unseasonable speculations, he probably found that his residence in Holland had been rendered less agreeable. Under the pretext of drinking the medicinal waters, he proceeded to Spa, and afterwards withdrew to Mentz, where the Jesuits gladly received the lost sheep returning to the sheepfold. From this place, on the 14th of April 1591, he addressed a canting letter to Delrio, a learned father of the same order; and only a short time elapsed before he was publicly reconciled to that church whose communion he had renounced as often as it suited his interest. So true it is that the bigots of a corrupt church are easily satisfied with a specious show of outward conformity, while the disguise of their votary is too transparent to deceive any one who is unwilling to be deceived. On ascertaining that there was no hope of his returning to

[2] See Bayle, Dictionaire Historique et Critique, tom. ii. p. 1723.

Leyden, the curators of the university manifested the utmost anxiety to find another scholar of equal and even superior attainments; and with true discernment they selected Joseph Scaliger, a man distinguished beyond all others by the extent and solidity of his learning. The rulers of the state acted with conspicuous liberality towards him, and afterwards towards Salmasius; "who," as Dr Bentley has remarked, "were invited out of their own country with the solemnity almost of an embassy, that they would honour a potent republic with their presence, and accept of a noble pension without any incumbrance of an office."[1] In many respects, Scaliger was greatly superior to Lipsius, and in none more than in the knowledge of the Greek language and literature, both of which his capacious mind had embraced in their entire compass. His advice and example had a great and lasting influence in recommending this study to the youth of his adopted nation, in which it long continued to flourish with a degree of vigour scarcely equalled in any other country of Europe.[2]

Having entered Mentz as a heretic and quitted it as a good catholic, he afterwards lingered for about two years at Spa and Liege. During this interval, many advantageous offers were made to him by princes and by dignitaries of the church. One offer, not from a king or cardinal, but from a private individual, deserves to be recorded: Benedictus Arias Montanus, a learned Spaniard whose name is so frequently mentioned in the annals of biblical literature, repeatedly urged him to come and share his income during his life, and to be the heir of all his property at his death. But the love of his native land prevailed over many other inducements, and Lipsius finally returned to Louvain as professor of history and eloquence. His salary as a professor amounted to eight hundred florins; and with the title of historiographer royal, Philip the Second bestowed upon him a pension of one thousand. The archduke Albert, governor of the Netherlands, added two hundred florins, and nominated him a member of the council; but having no wish or aptitude to engage in public affairs, he wisely restricted himself to the duties of his academical office. He taught with much ability, and with high reputation, but his lectures did not attract a numerous auditory; the students of that university having been trained by the Jesuits to set a higher value upon scholastic disputation than upon classical erudition.[3] He however continued with unabating ardour to pursue his favourite investigations, and about this period he composed several of his antiquarian works. "De Cruce libri tres, ad sacram profanamque Historiam utiles," appeared in 1595; "De Militia Romana libri quinque; Commentarius ad Polybium," in 1596; "Poliorceticωn, sive de Machinis, Tormentis, Telis, libri quinque," in the same year; "Admiranda, sive de Magnitudine Romana, libri quatuor," in 1598; "De Vesta et Vestalibus," in 1603. In 1604 he published "Manuductionis ad Stoicam Philosophiam libri tres, & Physiologiæ Stoicorum libri tres, L. Annæo Senecæ, aliisque Scriptoribus illustrandis." "Monita et Exempla Politica, libri duo, qui Virtutes et Vitia Principum spectant," followed in 1605. In the course of the same year he published his edition of Seneca the philosopher, and likewise "Lovanium, sive Oppidi et Academiæ ejus Descriptio." It would have been well for his reputation if he had adhered to such lucubrations as these, instead of occupying himself with miserable details of the miracles of our Lady of Hall and of Zichem. In 1604 he published "Diva Virgo Hallensis; Beneficia ejus et Miracula fide atque ordine descripta;" and in 1605 "Diva Sichemiensis, sive Aspricollis; nova ejus Beneficia et Admiranda." These abject tales of superstition exposed him to the ridicule and contempt of protestants, nor have the more rational papists commended him for such a manifestation of his zeal. His idolatry of the wooden goddess[4] afforded occasion for several controversial tracts; and the character of Lipsius was not much indebted to those friends who undertook his vindication. One of his fiercest antagonists was our learned countryman George Thomson, who was a protestant clergyman in France, and the author of several works in French as well as Latin.[5] In the year 1602 the professor had suspended his silver pen in the chapel of our Lady of Hall, to whose intercession he ascribed his recovery from a painful disease; and his votive tablet was ornamented with an effusion in Latin verse, not remarkable for the elegance of the composition. Here we very clearly discern the spirit of pagan idolatry; and it was under the same cloud of superstitious delusion that he awaited the approach of death. His biographer has deemed it worthy of record, that, when the spark of life was nearly extinct, he prayed with great fervour to the blessed virgin: of his reliance on the mercy of God through the atonement and mediation of Christ, we find a less anxious commemoration. With his dying breath he directed his wife to deposit his academical gown at the altar of the virgin in the church of St Peter; and having now testified as much false and as little true devotion as the five priests in attendance could require or expect, he expired on the 23d of March 1606, in the fifty-ninth year of his age. According to the direction of his testament, his remains were interred before the altar of the virgin in the church of the Franciscan friars. His death was lamented and his merits were extolled in prose and in verse by many different writers. One of his admirers undertook to prove that he was a good catholic; and of what materials a good catholic may be composed, we have already had occasion to state. Another, Wower of Antwerp, thought himself well employed in defending the propriety of his devout dedication of an old gown edged with fur; an act of driveling imbecility which had exposed his memory to much sarcastic animadversion.

[1] Bentley's Dissertation upon the Epistles of Phalaris, p. c.

[2] "Sub ipsa academiæ incunabula Leidæ bonas literas docuit Justus Lipsius, perfectus literis Latinis, Græcarum mediocriter peritus. Is dicere ausus est, Græcas literas homini erudito decoras esse, necessarias non item. Quod stultissimum dictum Isaaco etiam Casaubono, quo non fuit leuioris naturæ criticus, vehementer bilem movit. Sed bonum factum, quod tam perniciosa literis opinio nullas radices egit. Mox enim tamquam cœlo missus Josephus Scaliger, cui Batavi prope omnem rectum ingenii cultum, quem ex eo tempore ceperint, si grati esse velint, acceptum referre debent, Scaliger igitur cum ceteras ingenuas artes, tum Græcas literas, earumque cum Latinis conjunctionem, in his regionibus fundavit. Scaligerana disciplina per Grotios, Heinsios, Gronovios, Grævios, et alios usque ad patrum nostrorum memoriam propagata est." (Ruhnkenii Elogium Tiberii Hemsterhusii: Opuscula, tom. i. p. 268.)

[3] "Docet vir doctus," says Scultet in allusion to Puteanus, "ut et ante ipsum Lipsius, in sterili auditorio, non alia de causa (ex magno viro hoc audivi) quam quod juventus a melioribus studiis ad tricas disputationum scholasticarum per Jesuitas avocatur: a quibus hominibus, imperium in orbis terrarum academias affectantibus, nihil aliud quam barbarica politiorum literarum captivitas est expectanda." (De Curriculo Vitæ, inprimis vero de Actionibus Pragensibus Abrah. Sculteti, p. 66. Emdæ, 1625, 4to.) Erycius Puteanus was the immediate successor of Lipsius.

[4] An anonymous work, written by P. Denaisius, a German lawyer, was published under the following title: "Dissertatio de Idolo Hallensi, Justi Lipsii Mangonio et Phaleris ornato, atque producto." Heidelbergæ, 1605, 4to. This dissertation was answered by a Carmelite friar named Anastase Cochlet: "Palæstrita Honoris D. Virginis Hallensis pro Justo Lipsio." Antv. 1607, 8vo.

[5] Vindex Veritatis: adversus Justum Lipsium libri duo. Prior insanam ejus religionem politicam, fatuam nefariamque de Fato, sceleratissimam de Fraude doctrinam refellit. Posterior Ψευδοπαρθένου Sichemiensis, id est, Idoli Aspricollis, et Deæ ligneæ miracula convellit. Uterque Lipsium ab Orco Gentilismum revocasse docet. Auctore Georgio Thomsono Andreapolitano Scoto-Britanno. Londini, 1606, 8vo. The defence of Lipsius was undertaken by Claude Dausquei, a canon of Tournay, who published a work entitled "Scutum duplex, alterum B. Virginis Aspri-Collensis, alterum J. Lipsii; utrumque adversus Agricolæ Thracii satyricas petitiones." Duaci, 1610, 8vo. Thomson is mentioned in the following terms by Dominicus Baudius: "Georgium Thomsonum amo quidem et æstimo plurimum, ob studium bonarum partium, et egregios in solida doctrina progressus; sed, ut verum apud te fabuler, nullo modo possum probare nimiam ejus violentiam atque asperitatem in nostrum Lipsium: cujus quidem Divarum sanos omnes pudet pigetque, sed tamen majore cum reverentia tractandum fuit præstantissimum pene ingenium hujus seculi, et qui pro parte sua strenue tutatus est literarum gloriam." (Baudii Epistolæ, p. 298. edit. Lugd. Bat. 1650, 12mo.) See likewise p. 242. and Camdeni Epistolæ, p. 71. Lond. 1691, 4to. His treatment of Lipsius is more strongly censured by Scaliger: "De libro Georgii Thomsoni gratias ago. Mitius illi cum Lipsio agendum, et alia via cum illo congrediendum fuit. Nam præfractam illam et gladiatoriam violentiam non laudo. Non enim tanquam vindex veritatis, ut ipse profitetur, sed tanquam ultor offensæ alicujus cum eo agit, quum tamen ab eo nunquam ne verbulo quidem ullo læsus aut perstrictus fuerit." (Scaligeri Epistolæ, p. 809. Lugd. Bat. 1627, 8vo.) George Thomson was born at St Andrews, and studied in the university of his native city. Here he took the degree of A. M. and was incorporated at Oxford on the 30th of August 1605. (Wood's Fasti Oxonienses, part i. col. 309. Bliss's edit.) He was appointed minister of the reformed church at Châtaigneraye in Poitou. His command of the French language, and his eloquence as a preacher, are celebrated by John Dunbar. (Epigrammaton centuriæ sex decades totidem, p. 191. Lond. 1616, 8vo.) Under the date of 1617, we find the following obituary notice by Robert Boyd: "Mr Thomson, pasteur de la Chaistaignoraye, demeurant à la laiterie en Poytou;

> Vidit homo frigere suæ miracula divæ,
> Crassaque pro calido stragula thure dedit.

The personal appearance of Lipsius presented nothing very striking or dignified. Le Mire, who abounds in rhetorical flourishes, is pleased to inform us that he had a divine twinkle in his eye; but he does not attempt to disguise the fact, that many of the strangers who came to visit him were not a little disappointed at the meanness of his aspect. He had an ample forehead, and was of an ordinary size and shape; but during the latter part of his life, his appearance was much affected by the diseased state of his liver. He lived in a plain style, and retained only one man servant, who likewise acted as his amanuensis. Nature had denied him all relish for music; but from his literary toils he found an agreeable relaxation in the cultivation of his garden, which was planted with a variety of flowers, and was particularly rich in tulips. His biographer has likewise thought it worthy of notice that he was always fond of dogs, and that during his last residence at Louvain he generally kept three, one of them being of a Scotish breed.

Lipsius was a great master of the Latin language and literature. He has evinced much critical skill, as well as much erudition, in illustrating many of the ancient authors, and many different branches of Roman antiquities. His lucubrations on the poets are not in general very felicitous, nor did his taste particularly qualify him for this department of classical criticism: of the style and scope of historians, philosophers, grammarians, and rhetoricians, he was a more competent judge. In the Greek language he was not eminently skilled; and he has occasionally treated of subjects which required that knowledge in which he was somewhat deficient. His treatise on the military affairs of the Romans is founded on the Greek text of Polybius, which he transcribes and expounds; but, according to the opinion of Casaubon, where that text was formerly obscure, he has left it without any new elucidation. It is another charge against the same work, urged by Scaliger and Salmasius,[1] and repeated by many later writers, that the materials are in a great measure stolen from the Italian treatise of Patrizi.[2] Nor is this the only occasion on which an accusation of downright plagiarism has been preferred against him: Muretus complained of his having appropriated some of his emendations on Tacitus; and Faber, in more indignant terms, averred that from his *Semestria* Lipsius had without acknowledgment borrowed the best part of the materials for his treatise on the gladiators. Torrentius and other writers had similar charges to prefer against him, nor is it easy to believe that these accusations were destitute of all foundation.[3]

The political writings of Lipsius possess little or no value, except as a mere collection of facts and quotations. Here he displays no liberality or enlargement of mind; and beyond the limits of classical erudition, he appears to have been a man of very slender judgment. His two treatises on the Stoic philosophy are however of more interest and importance. His taste in composition was singularly quaint and affected, nor does he seem to have retained the power of conveying any information in plain and direct terms. This vitiated mode of writing excited the disgust of some of his most learned contemporaries; and on the Latinity of Lipsius a volume of 560 pages was published by H. Stephanus.[4] A considerable portion of it is however occupied with considerations respecting a war with the Turks; and this, says Scaliger, appeared so ridiculous that some person proposed to entitle it "De Lipsii Latinitate *adversus Turcam*." "The style of Lipsius," says Dr Jortin, "is execrable, in his later compositions; for in his

---

homme scavant, disert, joyeuse, entier, et d'un fort agréable conversation." (Bannatyne Miscellany, vol. i. p. 289.) Thomson is the author of a large volume entitled "La Chasse de la Beste Romaine: où est refuté le xxiii. chap. du Catechisme et Abregé des Controverses de nostre temps touchant la Religion Catholique, imprimé à Fontenay le Comte en l'an M.DC.VII. et est recerché et evidemment prouvé que le Pape est l'Antichrist. Par George Thomson, Pasteur de l'Eglise Reformée de la Chastegneraye." Rochelle, 1611, 8vo. Geneve, 1612, 8vo. Some copies of the second edition likewise bear Rochelle. Some passages of this elaborate work were attacked by René le Corvaisier, in "La Chasse au Loup Cervier, contre les Calomnies de G. Thomson." Paris, 1612, 8vo. Thomson strenuously defended himself in "La Desroute de la Chasse du Loup Cervier; ou, Refutation du Traicté du Ieusne, fait par Maistre René le Corvaisier, soi disant Theologien de la Faculté de Paris: contre quelques passages par lui attaqués en la Chasse de la Beste Romaine. Par George Thomson," &c. Rochelle, 1612, 8vo. Thomson had at an earlier period published a French version of Napier's commentary on the Revelation, under the subsequent title: "Ouverture de tous les Secrets de l'Apocalypse ou Revelation de S. Iean, par deux traités, l'un recerchant et prouvant la vraye interpretation d'icelle, l'autre appliquant au texte ceste interpretation paraphrastiquement et historiquement, par Iean Napeir (c. a. d.) Nonpareil, Sieur de Merchiston: reveue par lui-mesme, et mise en François par Georges Thomson Escossois." Rochelle, 1602, 4to. Rochelle, 1605, 8vo. Rochelle, 1607, 8vo. To the second edition he added "Quatre Harmonies sur la Revelation de S. Iean." His Latin poems are partly reprinted in the *Delitiæ Poetarum Scotorum*, tom. ii. p. 509-38.

[2] La Militia Romana di Polibio, di Tito Livio, e di Dionigi Alicarnaseo, da Francesco Patricii dichiarata, e con varie figure illustrata: la quale a pieno intesa, non solo darà altrui stupore de' suoi buoni ordini e disciplina, ma ancora, in paragone, farà chiaro quanto la moderna sia difettosa e imperfetta. Ferrara, 1583, 4to.

[3] Thomasii Dissertatio philosophica de Plagio Literario, § 115. 222. 487. Lipsiæ, 1673, 4to. Crenii de Furibus Librariis Dissertationes epistolicæ, p. 95. Lugd. Bat. 1716, 12mo.

[4] De Lipsii Latinitate (ut ipsimet antiquarii antiquarium Lipsii stylum indigitant) Palæstra I. Henr. Stephani, Parisiensis, nec Lipsiomimi, nec Lipsiomomi, nec Lipsiocolacis, multoque minus Lipsiomastigis, &c. Francofordii, 1595, 8vo.

youth he wrote far better, till he fell into a broken, incoherent, sententious, oracular, and figurative language, not through incapacity of doing better, but through an affected and vitiated taste. He had a few disciples, who imitated him, and wrote ten times worse than he, because they had not his learning, and his fancy, and vivacity; he was ingenious, and they were dull."[1] His Latinity has been zealously vindicated by Klotz, who was however a lover of paradoxes; nor is it very probable that his arguments have made much impression on any scholar of a genuine taste for classical composition.[2]

The epistles of Lipsius, amounting to the number of a thousand, occupy an entire volume in the collection of his works; and to this number a very large addition was afterwards made by Burman.[3] Many of them relate to topics of literature, and are very elaborate. On epistolary composition he has left a brief treatise, entitled "Epistolica Institutio." Another of his short tracts may likewise deserve to be mentioned, namely, "De Bibliothecis Syntagma," which relates to the libraries of ancient times. His only labour as a civilian is a collection of "Leges Regiæ et Leges Decemvirales," to which he has however added no illustrations. Of his critical treatises he published a collection under the title of "Justi Lipsii Opera omnia quæ ad Criticam spectant." Antv. 1585, 4to. Lugd. Bat. 1596, 8vo. An elegant edition of his works appeared with the subsequent title: "Justi Lipsii, V. C. Opera omnia, postremum ab ipso aucta et recensita: nunc primum copioso rerum indice illustrata." Antverpiæ, 1637, 4 tom. fol. A life of the author by Aubertus Miræus, or Aubert le Mire, and various panegyrics and defences, are inserted in the first volume. The collection of his works is sometimes described as consisting of six folio volumes; but this enumeration includes his edition of Tacitus and Velleius Paterculus, forming one volume, and his edition of Seneca the philosopher, forming another volume of the same size. Of his original works there is a more recent edition. Vesaliæ, 1675, 4 tom. 8vo. The third volume contains seven very slight tracts on Roman antiquities, which are not inserted in the folio edition, and which ought never to have been printed. Lipsius contributed brief annotations on Catullus, Tibullus, Propertius, Martial, the younger Pliny, Florus, Suetonius, and Valerius Maximus; but his reputation as an editor chiefly depends on his emendations and elucidations of Seneca, and more especially of Tacitus.[4] (x.)

LIQUEFACTION, an operation by which a solid body is reduced into a liquid by the action of heat.

LIQUID, a body which has the property of fluidity, as water, mercury.

Liquid, amongst grammarians, is a name applied to certain consonants which are opposed to mutes. Thus *l*, *m*, *n*, and *r*, are liquids.

LIQUOR, a name for any fluid substance of the aqueous or spirituous kind. The principal beverage amongst the Jews, as well as the Greeks and Romans, was water, milk, and the juices of various plants infused therein. For a long time, under the commonwealth of Rome, wine was so scarce, that in their sacrifices to the gods the libations were made with milk only. Wine did not become common there till the year 600 of the city, when vines began to be planted.

LIS, or Lys, John Vander, painter of history, landscapes, and conversations, was born at Oldenburg in 1570, but went to Haerlem to place himself as a disciple under Henry Goltzius; and as he was endowed with great natural talents, he soon distinguished himself in that school, and imitated the manner of his master with great success. He adhered to the same style till he went to Italy, where, having visited Venice and Rome, he studied the works of Titian, Tintoret, Paolo Veronese, and Domenico Fetti, so effectually, that he improved his taste and judgment, and altered his manner entirely. He soon received marks of public approbation; and his compositions became universally admired for their good expression, their lively natural colouring, and the sweetness and delicacy of his pencil; although it must be acknowledged that he could never totally divest himself of the ideas and taste peculiar to the Flemings. His subjects were usually histories taken from the sacred writings, or the representations of rural sports, marriages, balls, and villagers dancing, dressed in Venetian habits; all which he painted in a small as well as a large size, with a number of figures, well designed, and touched with a great deal of delicacy. He likewise painted naked figures admirably, with natural and elegant attitudes, and a very agreeable turn of the limbs. A capital picture of this master is, Adam and Eve lamenting the death of Abel, which is admired, not only for the expression, but also for the beauty of the landscape; and in the church of St Nicholas at Venice is another of his paintings, representing St Jerome in the desert, with a pen in his hand, and his head turned to look at an angel, who is supposed to be sounding the last trumpet. The colouring of this picture is rather too red; but it is designed in a fine style, and charmingly pencilled. The paintings of this master are very rarely to be purchased, He died in the year 1629.

Lis, *John Vander*, of Breda, an historical painter, was born at Breda about the year 1601, and became a disciple of Cornelius Polemburg, whose manner he imitated with extraordinary exactness, in the tint of his colouring, his neatness of pencilling, and the choice of his subjects. There are some paintings of this master which, though they appear to have somewhat less freedom and lightness of touch, are nearly equal to those of Polemburg, and are frequently taken to be his.

LISBON, a city of Portugal, the metropolis of that kingdom, as well as of the province of Estremadura, in which it is situated. It is built on the banks of the river Tagus, which is a most secure and capacious harbour, well defended, and capable of admitting 10,000 sail of vessels, without danger to them. The only difficulty is the bar at the entrance, which makes it hazardous either to enter or depart without the aid of skilful pilots. Between the bar and the city the strong castle of Belem, under whose guns all ships must pass, is a sufficient protection. Few finer objects can be seen than a panoramic view from the harbour of Lisbon. The smooth expanse of water studded with ships, the vineyards on the surrounding hills, interspersed with villas, and the magnificent city extending two miles along the shore, afford a coup d'œil which has few equals.

---

[1] Jortin's Life of Erasmus, vol. i. p. 466.—Grotius entertained nearly the same opinion of his style: "Cum floridum ipsi et profluens natura haud abnegaret, alterum maluit dicendi genus, consisum quidem, nec sine festivitate, sed vere novum obtentu antiqui: quod cum imitarentur, quibus ingenii judiciique non idem fuit, ad corruptissima quæque deventum est." (Hist. de Rebus Belgicis, lib. v. p. 378.)

[2] Klotzii Opuscula varii argumenti, p. 1. Altenb. 1766, 8vo.

[3] Burmanni Sylloge Epistolarum, tom. i. ii. The correspondence of Lipsius occupies all the first volume, and 193 pages of the second.

[4] "Lipsii opera ita probata est viris intelligentibus, ut et *Sospitator Taciti* diceretur, et inter principes interpretum referretur." (Fabricii Bibliotheca Latina, tom. ii. p. 396. edit. Ernesti.) With the works of Tacitus he was so familiarly acquainted, that, according to the statement of De Rossi, he could repeat them from beginning to end. (Erythræi Pinacotheca tertia, p. 2.) This morsel must however be taken with a grain of salt.

Lisbon is a city of great antiquity; it was known in remote periods by the name Ulyssippo, and its origin attributed to Ulysses. It was a *municipium* under the Roman government, and one of the favourite cities under the Moorish yoke. It was regained from the African marauders in 1154, by Alphonso, who had a few years before assumed the regal power, and who was assisted by a fleet of adventurers bound on a crusade to the Holy Land. Since that period it has continued the metropolis of Portugal, an independent kingdom, except from the year 1580 to 1640, when it was united to the Spanish monarchy.

From the vicissitudes this city has experienced, we may expect to find it abounding in Phœnician, Roman, and Moorish antiquities; but the tremendous earthquake which it suffered in 1755 buried most of what then remained in a heap of ruins. After the dismal catastrophe of that period, the city rose again with unexampled rapidity, and with a beauty and splendour far exceeding its former condition. The traces of this calamity are not, however, wholly obliterated. Near the river, and the Praça di Commercio, large masses of ruined churches and convents are visible amongst the modern buildings; and the fractured strata of the rocks on which these stand, still show the nature of the concussion which destroyed the former city. This city seems exposed to this calamity, as there have been frequent shocks of earthquakes since; and indeed few years pass without some slight indications of a tendency in the earth to similar *tremblemens*. The streets of Lisbon are of competent breadth, and paved; but, owing to the inequality of the ground on which they stand, and their slippery state, they are uncomfortable to walk or ride through. The attention of a vigilant police is wanted to enforce a greater observance of cleanliness. As few of the Portuguese nobility reside on their estates, their residences within the city are very splendid; and some of the richer merchants have houses, which in appearance rival those of the higher orders; but the habitations of the lower classes of the inhabitants are miserable and disgusting by their excessive filthiness.

The public buildings are very spacious; and some of the few which sustained the concussion of 1755 exhibit fine specimens of ancient architecture. The church of Belem is one of these, and though two of the columns which supported the roof were then thrown down, and have since been replaced by two mis-shapen masses of modern masonry, it exhibits the finest specimen of the Arabesque-Gothic style of building. The royal palace is finely situated on the banks of the Tagus at Belem, but, being composed of wood, is not equal to the general taste of the other public buildings. The most imposing object near Lisbon is the aqueduct, which conveys fresh water to the city, and which in grandeur yields to no work of ancient or modern times. The cathedral is a large and magnificent building, and endowed with a revenue estimated at more than L.100,000 sterling annually.

Lisbon is enriched with such establishments as usually adorn the capitals of kingdoms. It possesses an academy of sciences, a botanic garden, a well arranged cabinet of natural history, some public libraries, amongst which that of the Regalia contains upwards of 80,000 volumes, a college for the nobles, and several other seminaries. Amongst other charitable institutions, is an hospital, where the sick of all countries are freely admitted and relieved.

The climate of Lisbon is remarkably salubrious, and is sought after by invalids from the more northern countries, for relief in pulmonary complaints. It is thought that the water drunk in this city has a tendency to alleviate these maladies. This water, which is brought from Montelavar by the aqueduct, is strongly impregnated with carbonate of lime, and, on analysis, is like the water of Clifton, but has a greater quantity of lime in a state of suspension.

The markets of Lisbon are most profusely supplied with every article that can administer to human appetite. The consumption of animal food is small, that of beef exceeding that of mutton in a very great degree; but, for the number of inhabitants, the quantity of animal food consumed in Lisbon is only one eighth of that which London requires to supply it. Fish, both from the sea and the rivers, is abundant and cheap. Fruit of every kind, and flour of excellent quality, are to be purchased; and garlic, which seems to be one of the articles in most extensive demand, is furnished in prodigious quantities.

Before the great earthquake of 1755, the city of Lisbon was calculated to contain 150,000 inhabitants; but, by the census taken in 1804, the number amounted to 240,000. The removal of the court to Brazil did not diminish the population, but it has since declined, so that in 1830, by the last census, there were only 200,000, which, indeed, was both increased and enriched by this city having been during the peninsular war the focal point through which communication with the army was maintained, and the depôt for the ammunition, provisions, and recruits, destined to support the forces employed in the interior of Spain and Portugal.

There are few people in Lisbon occupied in manufactures. Some fine woollen cloths are made, some linens, and a quantity of silk goods more than equal to that of both the others. The greatest taste of this city is displayed in its jewellery business, in which, though rather tawdry than elegant, they excel. The goldsmiths and silversmiths are excellent workmen. As a specimen of the best faculties exercised in that branch, it deserves to be noticed, that the splendid service of plate presented to the Duke of Wellington by the government of Portugal was wholly made in Lisbon; and no person was permitted to execute the least part of the work who was not a native of the kingdom. This service, both for value and for the exquisite workmanship, is the first collection that was ever seen, and far exceeds that of any royal household in Europe.

The foreign trade of Lisbon is second to no city in Europe excepting that of London. Its domestic productions, wine, oil, fruits, and bay salt, are conveyed to all the northern parts of the continent of Europe, but more especially to England, with which is the principal commerce. It receives in return from every country the articles in which it excels; from Russia, hemp, flax, and other naval stores; from the other parts in the Baltic Sea, linens, iron, steel, salted fish, timber, pitch, and tar; from Germany and Holland it obtains linens, corn, and some other commodities. England makes returns in cloths, linens, cotton, hardware, porcelain, and the various products of its looms, its forges, and its kilns. France supplies some linens, and the more fanciful articles of its tasteful industry. These varied commodities, received at Lisbon, are partly consumed in Portugal, whilst a very considerable proportion of them are destined for re-exportation to the transmarine settlements.

The commerce of Lisbon is considerable with the Portuguese establishments in China, in India, and on both sides of the continent of Africa. The latter consists principally of such articles as are required to be given in exchange for human beings, in that abominable traffic denominated the slave-trade, but which deserves to be stigmatized as the commerce of cruelty and the stimulus to murder and barbarism. Brazil furnished for a long period the great rudiments of the distant trade of Lisbon. Its sugars were distributed from hence to all the continental ports, where they obtained the name of the port at which they had first been received in Europe. The cotton from that country, before the recent encouragements to its growth had given birth to its present enormous production, all centred in Lisbon; and it was the entrepôt for the gold, the silver, and the precious stones which the mines of Brazil yielded.

The removal of the seat of the Portuguese government from the European metropolis to its American dominions, caused a great revolution in the commercial relations of both parts of the empire. Brazil, having quitted its colonial character, had its ports opened to the commercial ships of all nations; the transit trade of Lisbon was in some measure terminated; but the alteration communicated such a stimulus to Brazil, and its population, its wealth, and its productions, increased so much within the first ten years that elapsed after the emigration of the court, that, after allowing for what passed direct to and from Brazil in its intercourse with other countries, its transactions of commerce with Lisbon were as great as before the removal of the government.

We have no authentic accounts of the foreign imports and exports; but some judgment may be formed from the returns of the vessels that entered the port in the years, 1829, 1830, and 1831, as furnished by the British consul:—

Countries.	Ships in 1829.	Ships in 1830.	Ships in 1831.
British	322	294	230
Portuguese	320	242	131
Foreign	560	692	308
Total	1202	1228	669

The average number of vessels, and their tonnage, which belonged to the port of Lisbon in the same three years, was, by the consular report, sixty ships, and of 9090 tons burden.

Lisbon is situated in north latitude 38. 42. 20., and west longitude from London 8. 37. 25., as determined by trigonometrical observations.

LISBURN, a town of Ireland, in the county of Antrim, situated on the western bank of the river Lagan, about seven miles south-south-west of Belfast. It is a large and busy town, being the second in commercial importance in the county. The manufacture of linen, muslin, and cambric, is carried on to a considerable extent. The principal public buildings are, a fine church, a market-house, an infirmary, a catholic chapel, and several dissenting places of worship. It was destroyed by fire in 1707, and rebuilt in its present form. It returns a member to parliament. It contains a population of 6201.

LISIEUX, an arrondissement of the department of Calvados, in France, extending over 339 square miles, and inhabited by 69,500 persons. It is divided into five cantons, and these into 142 communes. The capital is the city of that name situated at the junction of the two rivers Toques and Orbec. It was formerly fortified, but the ramparts have been converted into elegant promenades. It contains 1700 houses, and 11,500 inhabitants, who are employed in the woollen manufacture, and also, but to a greater extent, in making linen of a superior quality, known as *toiles crétonnes* through France. It is particularly celebrated for its bleaching and its dyeing. Long. 0. 10. E. Lat. 49. 11. N.

LISLE, or LILLE, an arrondissement of the department of the North, in France. It extends over 356 square miles, is divided into sixteen cantons, and subdivided into 129 communes, which together contain 241,800 inhabitants. The capital is the city of the same name, the most celebrated fortified place in Europe, and in the most fertile district of France. It is situated on the river Deule, which is navigable for barges and other small craft. The streets are broader than is usual in fortified places, and the new part of the city is handsome. Some of the public buildings, especially the theatre, the exchange, the barracks, and St Stephen's church, are fine. It contains 11,500 houses, and 62,500 inhabitants, who are occupied in numerous manufactures, though most of them are on a small scale. The most important are sugar-refining, glass-making, weaving linen, cotton, and woollen goods. The spinning of lace, and making of thread, employs many hands, as does the fabrication of pillow-lace. A vast quantity of seed-oil and of oil-cake is also made, both for domestic use and for exportation. Long. 2. 59. 11. E. Lat. 50. 37. 50. N.

LISLE, *Joseph Nicholas de*, an eminent astronomer and geographer, was born at Paris in the year 1688. His father having taught him the principles of grammar, he afterwards attended lectures in Mazarin College, where he delivered rhetorical exercises in the year 1706. A total eclipse of the sun having taken place on the 12th of March in that year, his taste for mathematics was thus discovered, and he was accordingly placed under a proper tutor, who taught him the elements of geometry, fortification, and mechanics; but his favourite study was the science of astronomy.

In 1707, he obtained the place of engineer at Martinico, which made him acquainted with the art of drawing; an acquisition which proved highly useful to him in his geographical labours, and also in the study of astronomy. His father having procured a copy of an Account of a Voyage to the South Sea, from his son's master, young De Lisle was excited by the perusal of it to the study of natural history, and began to make collections of insects, and sketch their varieties; but being afterwards persuaded that a study requiring such immense collections to be made as he found in Aldrovandus, was wholly incompatible with the unremitting attention which his favourite science required, he relinquished it entirely. The attention he paid to astronomical researches was so great, that he was considered as meriting the correspondence of some of the ablest astronomers of Europe at the early age of twenty-one. In 1709 he made a wooden quadrant, which he divided with the utmost accuracy, and which answered the intended purpose in his early observations. He likewise constructed a table for Cassini, of the right ascensions and declinations, adapted to all the degrees of latitude and longitude of the planets, and the obliquity of the ecliptic; and this table was made use of by Cassini in foretelling the occultations of the stars by the moon.

De Lisle being informed by Cassini in 1710 of his method of representing an eclipse of the sun, by the projection of a terrestrial parallel on a plane, he instantly conceived the idea of applying it to every part of the earth, by means of a globe mounted and prepared for that purpose. Such astronomers as he made acquainted with his project conceived it to be impracticable; but when the machine was completed, they bestowed the highest encomiums on the noble invention. The first memorable observation made by De Lisle was that of the moon, on the 23d of January 1712, after which his labours experienced some interruption from indisposition. About this time the situation of his father's numerous family rendered it necessary that he should provide for himself, so that he was obliged to make his astronomical knowledge subservient to the absurdities of astrology, receiving pecuniary presents from the regent for his services. He also received, in 1715, the grant of a pension of six hundred livres, on which occasion he calculated tables of the moon according to the Newtonian theory, prior to Halley's communications to him, which were printed in 1719. De Lisle was chosen a member of the Academy of Sciences in 1714.

In 1720 he delivered a proposal to the academy for ascertaining in France the figure of the earth, a design which was carried into execution some years afterwards. In 1723 he delivered to the same body a memoir on the transits of Mercury, wherein a method of calculating them was proposed by him, as well as the way in which they were to be observed, and the inferences to be deduced from these observations. He proposed the use of the quadrant in observing the transits of Venus and Mercury, which has been found superior to any other instrument for that important purpose, and is sanctioned since his day by the practice of the ablest astronomers.

De Lisle visited England in the year 1724, and there became acquainted with Newton and Halley, and had the honour of obtaining their approbation. Newton made him a present of his own portrait, and Halley gave him a copy of the tables which he had published in 1719. He was also created a member of the Royal Society, and enjoyed similar honours from every literary society in Europe before his death. In 1721 he received an invitation from Peter the Great to go to St Petersburg to fill the chair of astronomer in the Imperial Academy of Sciences. Upon the death of that emperor, his successor Catharine renewed the invitation, at the same time offering him a considerable pension, which he accepted, and, in 1726, set out for St Petersburg, accompanied by his brother Louis and M. Vignon, who were to act as his assistants. He reached St Petersburg in the month of October, and was established in the observatory erected by Peter the Great, which he occupied for twenty-one years. It was in every respect commodious, but extremely deficient in astronomical apparatus, which his own ingenuity and indefatigable application in a great measure supplied.

A transit of Mercury over the sun's disc was expected in the year 1740, which would not be visible in Europe, and therefore De Lisle undertook a journey to the distant regions of Asia; but after travelling through the inhospitable wilds of Siberia, the cloudiness of the atmosphere prevented him from observing the transit; a mortification which he endeavoured to support by his geographical and physical remarks, and in drawing up a description of the country. He constructed an interesting map of Russia, assisted by his brother Louis, who was appointed to make observations in the most distant parts of that immense empire. He was occasionally employed for the long period of forty years in making meteorological observations, which he executed with an accuracy almost incredible.

After a number of discouragements and difficulties, and the irregular payment of his pension, had been long experienced by De Lisle at St Petersburg, he returned disgusted to his native place, and was chosen professor of mathematics at the Royal College, where he rendered the most essential service to the sciences, by the important instructions which he gave to his numerous pupils, many of whom became afterwards the most distinguished characters, such as MM. de Lalande and Messier.

When the transit of Mercury over the sun was eagerly expected in 1753 by the greatest astronomers, De Lisle published an interesting map of the world, representing the effect of Mercury's parallaxes in different countries, that those places might be known which were proper for making such observations on the transit as might determine the distance of the sun. As the apparent orbit of the planet traversed nearly the centre of the sun, De Lisle made use of this circumstance to determine the diameter of that luminary. The last work of our author which was inserted in the volumes of the French Academy was a memoir on the comet which appeared in the year 1758, discovered by a peasant in the vicinity of Dresden.

It may perhaps be asserted with justice, that the most important service which he rendered to astronomers was the correction of the double error of Halley respecting the transit of Venus, looked for in the year 1761, as by this means he prevented many learned men from undertaking long voyages in order to observe it. About the year 1754, De Lisle was appointed by the king of France astronomical geographer to the marine, in which capacity he was employed to collect plans and journals of naval captains, to arrange them methodically, and to make extracts from them of whatever might be beneficial to the service. About the year 1758 he withdrew into retirement at the abbey of St Geneviève, where much of his time was spent in devotional exercises, and in acts of charity and beneficence. Still, however, he continued to prosecute those studies which had been so dear to him during the earlier part of his life. In 1768, he was seized with a scorbutic complaint, of which he was cured by his medical friends; but in the month of September of the same year he was seized with a species of apoplexy, which carried him off on the 11th of that month, in the eighty-first year of his age.

His extraordinary merit as a man of science may in some measure be gathered from this concise account of his life; and, as a citizen of the world, his piety was unaffected, his morals pure, his integrity undeviating, his spirit generous and disinterested, and his whole manners highly amiable. The only publication of his, besides those already mentioned, consisted of Memoirs illustrative of the History of Astronomy, in two vols. 4to.

LISMORE, one of the Hebrides, or Western Islands of Scotland, belonging to Argyleshire, situated at the mouth of Loch Linnhe, about nine miles in length, and from one to two in breadth. The surface is hilly and uneven; but the soil is fertile, and yields a sufficient quantity of grain for the support of the inhabitants; oats, barley, potatoes, and flax being the articles of crop generally cultivated. The whole island lies upon a rock of limestone, which article is exported in considerable quantities. In the lakes there are strata of marl found varying from ten to sixteen feet in depth. It was anciently the residence of the bishops of Argyle, and contained, until very recently, a Roman Catholic college for the education of the clergy of that persuasion in this part of the country. The ruins of an old castle are still to be seen, and in several places vestiges of fortified camps. The population amounted in 1831 to 1790.

LISMORE, a town of Ireland, in the county of Waterford, situated on the southern bank of the Blackwater, about twenty-six miles north-east of Cork. It was formerly a considerable city, being the see of a bishop, but has been often destroyed by fire, and is now a small, mean place. It possesses a small cathedral, and a castle situated on the verge of a rock which rises perpendicularly over the river. It has no manufacture of any kind, the inhabitants being principally engaged in agricultural pursuits.

LISSA, an island in the Adriatic Sea, being a part of the Austrian province of Dalmatia. It is fifty-seven square miles in extent, and contains 4557 inhabitants. Although it is mountainous, it is very productive in wine, oil, honey, figs, almonds, and silk, but deficient in corn. There are large flocks of sheep yielding excellent wool, and many goats, and upon the coast there are large fisheries. The chief town, of the same name, is on a convenient harbour, and contains, including the two adjoining hamlets of Banca, 2676 inhabitants. It is situated on the spot where formerly stood the celebrated city of Issa, noticed by Strabo.

LISSA, a city of Polish Prussia, in the government of Posen, and circle of Fraustadt. It is situated on the frontier towards Silesia, is a well-built city, in a sandy district. It contains two churches of Calvinists, one of Lutherans, and one of Catholics, two hospitals, 780 houses, with 7954 inhabitants, of whom 3640 are Jews. It enjoys considerable trade, chiefly carried on by the Jews, who make linen, woollen, and other goods. Long. 16. 32. 20. E. Lat. 51. 51. 55. N.

LIST, in commerce, the border of cloths or stuffs, serving not only to show their quality, but to preserve them from being torn in the operations of fulling, dyeing, &c. List is used on various occasions, but chiefly by gardeners for securing their wall trees.

List is also used to signify the enclosed field or ground wherein the ancient knights held their jousts and combats. It was so called, as being hemmed round with pales, barriers, or stakes, as with a list. Some of these were double, one for each cavalier, which kept them apart, so that they could not come nearer each other than within a spear's length.

Civil List, in the British polity. The expenses defrayed by the civil list are those which in any shape relate to civil government, as the expenses of the household; all salaries to officers of state, to the judges, and every one of the king's servants; the king's private expenses, or privy purse; and other very numerous outgoings. The civil list is indeed properly the whole of the king's revenue in his own distinct capacity; the rest being rather the revenue of the public or its creditors, though collected and distributed again in the name and by the officers of the crown. It now stands in the same place as the hereditary income did formerly; and as that has gradually diminished, the parliamentary appointments have increased. See England.

LISTER, Martin, an eminent English physician and naturalist, was born in 1638, and educated at Cambridge. He afterwards travelled into France, and on his return practised physic at York, and afterwards at London. In 1683, he was created doctor of physic, and became fellow of the College of Physicians in London. In 1698, he attended the Earl of Portland in his embassy from King William III. to the court of France (of which journey he published an account on his return), and was afterwards physician to Queen Anne. He also published, 1. *Historia Animalium Angliæ*, 4to; 2. *Conchyliorum Synopsis*, folio; 3. *Cochlearum et limachum exercitatio anatomica*, in four vols. 8vo; 4. Many pieces in the Philosophical Transactions; and other works.

LITANY, a solemn form of supplication to God, in which the priest utters some things fit to be prayed for, and the people join in their intercession, saying *we beseech thee to hear us, good Lord.* The word comes from the Greek λιτανεια, *supplication*, from λιτανευω, *I beseech.*

At first the use of litanies was not fixed to any stated time, but they were only employed as exigencies required. They were observed, in imitation of the Ninevites, with ardent supplications and fastings, to avert the threatening judgments of fire, earthquakes, inundations, or hostile invasions. About the year 400, litanies began to be used in processions, the people walking barefoot, and repeating them with great devotion; and it is pretended, that by this means several countries were delivered from great calamities. The days upon which these were used were called *rogation days.* These were appointed by the canons of different councils, till it was decreed by the council of Toledo that they should be employed every month throughout the year; and thus by degrees they came to be used weekly on Wednesdays and Fridays, the ancient stationary days for fasting. To these days the rubric of the episcopal church has added Sundays, as being the greatest days for assembling at divine service. Before the last review of the common prayer, the litany was a distinct service by itself, and performed some time after the morning prayer was over; at present it is made one office with the morning service, being ordered to be read after the third collect for grace, instead of the intercessional prayers in the daily service.

LITCHFIELD, a city in the hundred of Offlow, in Staffordshire, situated upon a branch of the river Trent, 119 miles from London by Coventry, and 124 by Northampton. It has been an episcopal city almost from the introduction of Christianity into this island; and the cathedral is said to have been first built in the year 300. It is a fine building, walled in like a castle, and, from its elevated situation, a prominent object over a great extent of country. A spire rises from the centre, 256 feet in height; and at the west end are two towers, terminating also in spires. This city was for a short period in the eighth century made the see of an archbishop; but was soon afterwards reduced again to a bishopric. In the year 1072, it was removed to Chester, and in 1102 to Coventry, and united to that see. The cathedral is a fine piece of architecture, and the interior is adorned with some marble monuments, particularly those of Dr Johnson and Mr Garrick, both natives of the city. The government is executed by a corporation consisting of two bailiffs and twenty-four burgesses, and sends, as before the passing of the reform act, two members to parliament. It is a county, with exempt jurisdiction. There is little trade, except what is internally carried on upon the canals. It has markets on Tuesdays and Fridays. The population amounted in 1801 to 4712, in 1811 to 5022, in 1821 to 6075, and in 1831 to 6723.

Litchfield, a county of Connecticut, United States, bounded on the north by Massachusetts, on the east by Hartford, on the south-east by New Haven, on the south-west by Fairfield, and on the west by New York. The face of the country is rough and mountainous; but the soil is good, yielding excellent crops of wheat and Indian corn, and affording fine pasturage. From the inland situation of the county, no maritime commerce can be carried on, and the inhabitants are almost wholly engaged in agricultural and manufacturing pursuits. The population amounted in 1830 to 42,855.

Litchfield, the capital of the above county, a post-town, situated about thirty miles west of Hartford, and thirty-one north-north-west of New Haven. The situation is elevated, and affords a beautiful and extensive prospect of the surrounding country. The town contains a court-house, a jail, a female academy, a law-school, a printing establishment, a bank, and nine places of worship. It is a good agricultural town, and possesses numerous mills and manufacturing establishments, cotton manufactories, iron-works, &c. Long. 73. 37. W. Lat. 41. 50. N. The population amounted in 1830 to 4456.

LITERARY, any thing belonging to literature.

Literary Property, or *Copyright.* See Copyright.

LITERATI (*letrados*, lettered), an epithet given to such persons amongst the Chinese as are able to read and write their own language. The literati alone are capable of being made mandarins. Literati is also the name of a particular sect, either in religion, philosophy, or politics, consisting principally of the learned men of that country, amongst whom it is called *jukiao*, or learned. It had its rise in the year of Christ 1400, when the emperor, to awaken the native affection of the people for knowledge, which had been quite banished by the preceding civil wars, and to stir up emulation amongst the mandarins, selected forty-two of the ablest of the doctors, to whom he gave a commission to compose a body of doctrine agreeable to that of the ancients, which was then become the rule or standard of the learned. The delegates applied themselves to the business with very great attention; but some fancied them rather to have wrested the doctrine of the ancients to make it consist with their own, than to have built up theirs upon the model of the ancients. They speak of the Deity as if that being were no more than mere nature, or the natural power or virtue that produces, disposes, and preserves the several parts of the universe. He is, say they, a pure, perfect principle, without beginning or end;

the source of all things, the essence of every being, and that which determines it to be what it is. They make God the soul of the world; they say he is diffused throughout all matter, and produces all the changes which occur in it. In short, it is not easy to determine whether they resolve God into nature, or lift up nature into God; for they ascribe to it many of those things which we attribute to the Deity. This doctrinc introduced a refined kind of atheism, instead of the idolatry which prevailed before. The work, being composed by so many persons of learning and parts, and approved by the emperor himself, was received with infinite applause by all the people. Many were pleased with it, because it seemed to subvert all religion; others approved of it, because the little religion that it left them could not give them much trouble. And thus was formed the sect of the literati, consisting of the maintainers and adherents to this doctrine. The court, the mandarins, and the persons of fortune and quality, and others, are generally amongst its adherents; but a great part of the common people still hold to their worship of idols. The literati freely tolerate the Mahommedans, because they adore, with them, the king of heaven, and author of nature; but they entertain a perfect aversion to all sorts of idolaters, and it was once resolved to extirpate them. The disorder this would have occasioned in the empire prevented it; and they now content themselves with condemning them, in general, as heresies, which they do solemnly every year at Pekin.

LITHARGE, a preparation of lead, usually in form of soft flakes, of a yellowish-red colour. If calcined lead be urged with a hasty fire, it melts into the appearance of oil, and on cooling concretes into litharge. The greater part of the litharge met with in the shops is produced in the purification of silver from lead, and the refining of gold and silver by means of this metal. According to the degree of fire and other circumstances, it proves of a pale or deep colour. The first has been commonly called *litharge of silver*, the other *litharge of gold.*

LITHGOW, William, a Scotchman, whose sufferings by imprisonment and torture at Malaga, and whose travels on foot over Europe, Asia, and Africa, seem to raise him almost to the rank of a martyr and a hero. He published an account of his peregrinations and adventures. Though the author deals much in the marvellous, the account of the strange cruelties which he gives us has yet an air of truth. Soon after his arrival in England from Malaga, he was carried to Theobald's upon a feather-bed, that King James might be an eye-witness of his "martyred anatomy," by which he means his wretched body, mangled, and reduced to a skeleton. The whole court crowded to see him, and his majesty ordered him to be taken care of, and he was twice sent to Bath at his expense. By the king's command he applied to Gondomar, the Spanish ambassador, for the recovery of the money and other things of value which the governor of Malaga had taken from him, and for L.1000 for his support. He was promised a full reparation for the damage he had sustained; but the perfidious minister never performed his promise. When he was upon the point of leaving England, Lithgow upbraided him with the breach of his word, in the presence-chamber, before several gentlemen of the court. This occasioned their fighting upon the spot; and the ambassador, as the traveller oddly expresses it, had his fistula, with which disorder he was afflicted, contrabanded with his fist. The unfortunate Lithgow, who was generally condemned for his spirited behaviour, was sent to the Marshalsea, where he continued a prisoner during nine months. At the conclusion of the octavo edition of his *Travels,* he informs us, that in his three voyages, "his painful feet have traced over, besides passages of seas and rivers, 36,000 and odd miles, which draweth near to twice the circumference of the whole earth." Here the marvellous seems to rise to the incredible, and to place him, in point of veracity, below Coryat, whom it is nevertheless certain that he far outwalked. His description of Ireland is whimsical and curious. This, together with the narrative of his sufferings, is reprinted in Morgan's *Phœnix Britannicus.*

LITHOGRAPHY.

Lithography is the art of taking impressions from drawings or writings made on *stone.*

The principles upon which this art is founded are, 1*st,* The quality which a compact granular limestone has of imbibing grease or moisture; and, 2*dly,* The decided antipathy of grease and water for each other.

A drawing being made upon the stone with an ink or crayon of a greasy composition, is washed over with water, which sinks into all the parts of the stone not defended by the drawing. A cylindrical roller, charged with printing-ink, is then passed all over the stone, and the drawing receives the ink, whilst the water defends the other parts of the stone from it on account of its greasy nature.

This process, therefore, depends entirely upon chemical principles, and is thus distinct from letter-press or copperplate printing, which are altogether mechanical. On this account it has in Germany been called *chemical printing;* and, as metallic plates can be prepared to be printed from in a similar manner, lithography is considered only as a branch of chemical printing.

I. HISTORY OF LITHOGRAPHY.

History of the art.

The invention of lithography was the result of accident. Its inventor, Alois Senefelder, the son of a performer at the theatre-royal of Munich, was placed for education at the university of Ingolstadt, as a student of jurisprudence; but after his father's death he attempted a theatrical career. Not succeeding in this, he became an author, though his poverty prevented him from publishing his works. He now tried many plans with copperplates and compositions, as substitutes for letter-press, in order to be his own printer. He found, in the course of his experiments, that a composition of soap, wax, and lamp-black, formed a good material for writing on his plates; that, when dry, it became firm and solid, and that it resisted aquafortis. Wanting facility in writing backwards on the plates, he got some pieces of Kilheim stone, as cheap materials, upon which he could practise after polishing their surfaces. One day being desired by his mother to take an account of some linen about to be sent to be washed, and having no paper at hand, he wrote the account on a polished stone, with his composition ink, intending to copy it at his leisure. When he was afterwards about to efface this writing, it occurred to him that he might obtain impressions from it; and, having eaten away the stone with acid for about the hundredth of an inch, he found that he could charge the lines with printing ink, and take successive impressions. This new mode of printing appeared to him very important, and he persevered through all difficulties in applying his discovery to practical purposes, and in improving it.

In the course of many experiments, he found that it was not necessary to have the letters raised above the surface of the stone, but that the chemical principles by which grease and water are kept from uniting, were alone sufficient for his purpose. This point obtained, lithography may be said to have been fully discovered. All that was required was the improvement of the materials, and the mode of working with them, and the construction of a proper press for taking the impressions.

The perseverance with which he followed up his experiments, in order to overcome the difficulties which successively arose in his progress, is astonishing, and the more so, considering the total want of method in his proceedings. Often did he waste months in surmounting a difficulty which a little knowledge, or a very little reasoning, would have enabled him to conquer immediately. His uniform plan seems to have been, to try the first thing that came to hand, and so on in succession, till chance rewarded his assiduity by presenting to him the material suited to his purpose.

The first essays he made to print for publication were some pieces of music, executed in 1796; but afterwards he attempted drawings and writings. The difficulty he had in writing backwards led him to the process of *transfer;* and the use of dry soap, which was found to leave permanent traces that would give impressions, naturally led to the mode of chalk drawings.

Having made considerable improvements, Mr Senefelder obtained, in 1799, a patent privilege for Bavaria, when he made known his process, and afterwards entered into partnership with Mr André of Offenbach, who proposed to establish presses, and take out patents at London, Paris, and Vienna. For this purpose Senefelder came to London with a brother of André's, and the invention having been much spoken of, under the name of *Polyautography*, most of the principal English artists made trials of it. Unfortunately, however, the art of printing from the stones was not then fully understood, and the difference between the materials of Germany and those of England, used both for the purposes of drawing and printing, caused constant failures, and the artists in succession abandoned the practice of it. To this cause is to be attributed the slow progress which lithography made for many years in England, as it was left entirely in the hands of *amateurs*, whose productions, generally speaking, did no credit to the art, and whose faults were in some degree supposed to be those of the art itself.

In August 1800, Senefelder, who had now separated from André, went to Vienna, where, after much difficulty, a patent was obtained, and extensive preparations were made, for applying his process to print cottons; but bad management, and some unfortunate circumstances, prevented his success, and he returned to Munich in 1806, leaving the establishment in other hands.

In 1806, Mr Mitterer, professor of drawing at the public school at Munich, practised lithography to multiply copies for the pupils, and is said to have invented the chalk composition in its present form, or at least to have improved it greatly.

From this period, the practice of the art has extended and improved rapidly, and more particularly at Munich, where several establishments were formed for the purpose of applying it to the fine arts, as well as for printing writings and official forms for the different departments of the government.

In October 1809, Senefelder was appointed inspector of the royal lithographic establishment at Munich, for printing from stone a complete map and survey of Bavaria; after which period he devoted his time to experiments, and to writing the history of his invention. Among other points of improvement to which his attention was directed, was a substitute for the stones, which are inconvenient to use on account of their weight; and they are also liable to break in the press, when used without due caution, or when they contain flaws. For this purpose he made a composition of drying oil, finely ground earth, and other substances, which was thinly spread over pieces of parchment; but nothing of this sort has hitherto been found to answer. The surface cracks after repeated wetting and exposure to the power of the press, and the printing ink then enters the cracks, and spoils the impressions. Thus a very small number only of good impressions can be obtained. A public exhibition of printing from this stone paper was made in London, on the 23d July 1821, by a partner of Mr Senefelder; but the result was not such as to induce much confidence in the ultimate success of the trials to form this desirable substitute of a light material for a heavy one.

In England lithography was never entirely given up from its first introduction in 1800, although it was but little practised after 1806, till its revival at the latter end of 1817. Since then it has been most sedulously cultivated, and with such success, that its importance as a branch of trade is now almost equal to the art of engraving.

In France but little was done in lithography till 1815, when it was established at Paris by Lasteyrie, and being taken up by good artists, it soon attained great excellence.

Since this period it has extended most rapidly, and there is not now a town of any importance, either in Europe, North America, or in the East or West Indies, where lithography is not practised.

II. DESCRIPTION OF THE MATERIALS, AND THE MODE OF PREPARING THEM.

1. *Of the Stones, and the manner in which they are prepared to receive the Drawings.*

Stones.

As calcareous stones will all imbibe grease and moisture, and effervesce with an acid (the use of which will appear when we speak of the process of printing), they are all capable of being used for lithography. Those are best adapted to the purpose which are very compact, of a fine and equal grain, and free from veins, or imbedded fossils or crystals.

The quarries of Solenhofen, near Pappenheim, in Bavaria, furnished the first plates, and none have as yet been found to equal them in quality. They are of a very uniform pale yellowish-white colour. The fracture is perfectly conchoidal. The beds divide into thin portions of considerable size, with perfectly flat surfaces, and were on this account carried to Munich, and other places, for paving kitchens and halls, and thus came in the way of Senefelder, when he discovered the chemical process of printing.

The stones of this quarry vary in their quality, but the best may be had in great abundance. Generally speaking, the hardest are the best, provided they are quite uniform in texture. Such are necessary for fine chalk drawings; softer ones may do for ink, or for coarser drawings in chalk.

In France, stones have been found near Chateauroux (*Departement de l'Indre*), of a similar colour to those of Solenhofen, and even harder and of a finer grain; but they are so full of large spots of a softer nature, that it is scarcely possible to get one perfect of a greater size than twelve inches square.

In England, a stone has been used for lithography which is found at Corston, near Bath. It is one of the white lias beds, but not so fine in grain, or so close in texture, as the German stone, and therefore far inferior. But it is good for transfers, and does tolerably well for ink drawings or writings. Another stone, found near Stony Stratford, is also used; but it is of a brownish-gray tint, and too dark in colour to show the effect of the drawing with sufficient clearness.

To bear the pressure used in taking the impressions, a stone twelve inches square should be at least an inch and a quarter thick. The thickness must increase with the size of the stone, but two inches and a half are a thickness sufficient for stones of three feet by three feet and a half.

The stones, when sawn to a proper size and thickness, are ground level by rubbing two of them face to face with water and sand, and very carefully examined with a straight-edge, to ascertain that they are perfectly level in all directions. This applies only to the side which is afterwards to receive the drawing, as the natural division of the stone is sufficiently true for the back.

To prepare them for chalk-drawings, two stones, which have been perfectly levelled, are well washed, in order to free them from any of the coarser grains of sand which have been previously used upon them. They are now to be placed on a board over a trough, and a small quantity of water and fine sand being strewed over the surfaces, they are to be rubbed face to face, adding occasionally a little fresh sand and water. The best sort of sand in England is that called silver sand for preparing the stone, and the common brown sand for giving a fine grain. The sands must be passed through a sieve of the fineness required, which will vary with the nature of the drawing; and the greatest care must be taken to have the sieves perfect, and to prevent any coarser particles of sand from being mixed with the rest. A single grain would fill the stone with innumerable scratches, which would all appear in the drawing. The upper stone is in this operation moved in small circles carefully and equally all over the under one, taking care not to move the one beyond the edge of the other, or the faces would become rounded. When the grain is equal, and sufficiently fine, the stones are carefully washed, and wiped with a clean cloth. The stone, thus prepared, should have, when dry, a perfectly uniform appearance in the colour and grain, and resemble a sheet of vellum. It should be free from scratches, and have no shining parts. The upper stone is always the finer grained of the two.

To prepare the stones for ink drawings or writings, the process just described is first followed; they are then well washed to get rid of the sand, and the same operation of rubbing two together is continued with powdered pumice-stone and water. When perfectly smooth, they are again washed, and afterwards separately polished with a large piece of fine pumice-stone, or Water of Ayr stone. The polish now given to the stone should be such as to show the reflection of objects to the eye placed close to the stone, and looking along it towards the light.

When a writing or drawing has been fully used, and the stone is to be again prepared, sand is strewed over the surface, and it is sprinkled with water, and rubbed with another stone, as before described, till all traces of the drawing has disappeared. After this, the stone is again prepared for a new drawing with fine sand, by being grained or polished, as before.

Ink drawings sink deeper into the stone than the chalk, and require the stone to be more ground away to efface them. The longer drawings remain upon the stone, the deeper the ink or the chalk penetrates.

2. *Lithographic Ink and Chalk.*

For these materials, the union of several qualities is required; and as no single substance possesses them all, it is necessary to combine several substances together.

Lithographic Ink.

Ink.

The qualities required in lithographic ink, by which is meant the ink for drawing on stone, are, first, that it shall have in its composition such a quantity of greasy or fatty matter as will secure its imparting to the stone, even when it is laid on in the most delicate lines, a trace strong enough to attract readily the ink afterwards to be applied by the roller; and, secondly, that this grease be so prepared, by being mixed with alkali and other substances, as to be easily soluble in water, and to flow readily from the pen or brush when used for drawing. Many receipts have been given for this purpose, but the following is one of the most approved; and, ordinary care being taken in its preparation, it will be found to answer.

Composition of Lithographic Ink for drawing on Stone.

Tallow candle	2 oz.
Virgin wax	2 oz.
Shell lac	2 oz.
Common soap	2 oz.
Lamp black, about one twentieth of the whole.	

These materials are prepared in an iron saucepan, with a cover. The wax and tallow are first put in and heated till they ignite; whilst they are burning, the soap must be thrown in in small pieces, one at a time, taking care that the first is melted before a second is put in. When all the soap is melted, the ingredients are allowed to continue burning till they are reduced one third in volume. The shell lac is now added, and as soon as it is melted, the flame must be extinguished. It is often necessary, in the course of the operation, to extinguish the flame, and take the saucepan from the fire, to prevent the contents from boiling over; but if, after the process above described, any parts are not completely melted, they must be dissolved over the fire without being again ignited.

Sometimes a larger proportion of wax is used, when only half of the soap is put in, and the burning goes on until the quantity is reduced one half. The remainder of the soap is then added over a fire which keeps the mass melted without igniting it.

The black, being previously mixed with thick varnish, such as will be described when we come to treat of printing inks, should now be added; and when it is completely dissolved, the whole mass should be cast on a marble slab, and a heavy weight laid over it, to render its texture fine. When cold, though not so hard, it should in its fracture have an appearance resembling Indian ink.

So much here depends upon the manipulation, that even the most experienced person can never be sure that the desired result is altogether attained, until the product is subjected to experiments; the mass may have been burned a little more or a little less than enough; too much or too little time may have been allowed to elapse betwixt the putting in of one ingredient and another: such circumstances, trifling as they appear, are quite sufficient to render the ink altogether unfit for use. It not unfrequently happens, therefore, that such faults as the following are to be found: If it has been too little burned, it may appear soft, and, if soluble, it may, when mixed with water, speedily become thick and slimy, in which case it must be re-melted and burned a little more; but if, on the other hand, it has been burned too much, it may appear to be composed of sand, and, when used, although it will flow pleasantly enough, may not have enough of grease left in it to attract the printing ink when applied. This fault may be corrected by remelting it, and adding a small quantity of soap and wax.

Keeping in view the principles here pointed out, any one can, after a few trials, make good lithographic ink.

Ink for Transfers.

This ink may be composed of the same materials as the ink for drawing on stone, with the addition of a little more wax. If it is too little burned, the lines of the writing or drawing will spread on being transferred to the stone; if too much, a sufficient quantity of grease will not be imparted to the stone to attract the ink from the roller when it is applied: but either of these defects may be corrected as before directed.

Lithographic Chalk.

Cha. This should have the qualities of a good drawing crayon; it should be even in texture, and carry a good point. It is, however, difficult to avoid making it too soft and greasy on the one hand, and too brittle on the other. For the chalk, as for the ink, more or less of the soap, wax, and tallow may be used, as the extent of the burning may render necessary; and the remedies pointed out for defects of the ink will enable the operator to judge of what is wanting.

The following proportions are the best:

Common soap	1½ oz.
Tallow	2 oz.
Virgin wax	2½ oz.
Shell lac	1 oz.

The manipulation is similar to that for the ink. It is well, however, to throw in a little of the wax just before the flame is extinguished. Less black must be mixed with the chalk than with the ink, its only use being to colour the drawing, so that the artist may see the lines he traces.

When the whole is well mixed, it should be poured into a mould, and very strongly pressed to prevent any bubbles, which would make the texture irregular.

3. *Mode of Drawing.*

Drawing. With these materials the artist proceeds to work on the prepared stone, taking care first to wipe the stone with a clean dry cloth. The ink being rubbed with warm water like Indian ink, is used on the *polished* stone; and it is to be observed, that a gradation of tints can be obtained only by varying the thickness of the lines, and the distance at which they are placed apart, as the line traced by the ink, being sound and unbroken throughout, receives the printing ink all over. Hence it follows, that the artist cannot gain any advantage by diluting the ink for the lighter tints of the drawing, as the printing ink will take effect equally upon all the lines, and at once render all of them equally black. The object of the artist is to mix the ink to that consistency which, whilst it works freely, shall yet be strong enough to stand perfect through the process of printing. A consistency a little stronger than writing ink is sufficient for this purpose.

The chalk cannot be used upon the polished stone.

The *grained* stone, prepared for chalk, being carefully wiped to free it from dust, must be drawn upon with the crayon as common drawing chalk is used on paper. The subject may be traced on the stone with lead pencil or red chalk, but care should be taken to do this very lightly, so as not to fill up any of the grain of the stone. In drawing, the degree of pressure of the hand will vary the strength of the tint, and it is desirable to give the requisite strength at once, as the surface of the stone is a little altered by receiving the chalk, and hence it does not take any additional lines with the same equality. Practice is necessary to give a command of the material, as it does not work quite like the common crayon, there being great difficulty in keeping a good point. There is also much difficulty in obtaining the finer tints found in the impression; and for the light tints it is necessary to put the chalk in a reed, as the metal port-crayon is too heavy to draw them, even without any pressure from the hand; and therefore the artist cannot draw them with freedom, as his touch will be unsteady, by being obliged to support the pencil from the stone.

It is necessary to observe the grain with which the stone is prepared, which should vary with the fineness of the drawing. Several pieces of chalk should be prepared to use in succession, as the warmth of the hand softens it.

It is useful to cut the chalk in the form of a wedge rather than a point, as it is less likely to bend in that form.

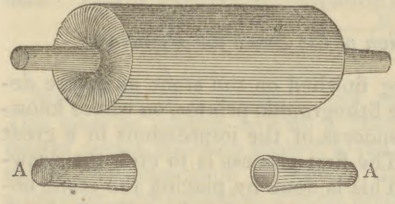
Small portions of the point will break off during the drawing; and these must be carefully removed with a small brush.

4. *Printing Press and Roller.*

The printing press for lithography does not differ materially from the ordinary copperplate press. A detailed description of one of the most approved construction will be given under the article Printing. Printing press.

The Roller.

The following is a representation of the roller:



The length may vary, Roller. but it ought to be full four inches in diameter. It is covered with flannel, rolled tightly three or four times round, and nailed at the ends. It is then covered with a stretched calf-skin, fitting quite tight. The seam must be made neatly with the boot-maker's closing stitch. The ends of the leather are gathered with a string, and tied round the projecting ends of the roller. Loose handles, A, A, made of thick leather, are put on these ends when it is used. The leather must be put on the roller with the smooth side outwards.

5. *Printing Ink.*

The printing ink is composed, as other printing inks are, Printing ink. of oil, varnish, and very fine lamp-black, well mixed together. To prepare the varnish, a saucepan is about half filled with pure linseed oil, and heated over a fire till it ignites from the flame of a piece of burning paper. It should then be allowed to burn till it be reduced to the degree required; and if, during the operation, there appear danger of its boiling over, it should be immediately taken off the fire, and the cover, which ought to fit quite close on the saucepan, must be put on to extinguish the flame. This is to prevent accidents; and the operator cannot be sufficiently cautioned against the danger attending the burning of the varnish, which ought never to be performed in a room with a boarded floor, or indeed in any part of a house. Wet sacks are the best things to put out the flame in case of accident.

Several inks must be prepared, differing in the degree of viscidity, or thickness of the varnish from which they are made, and the quantity of black mixed with them. The longer the oil is burned, the thicker the varnish becomes. The thinnest varnish is burned till it has lost nearly one fourth of its volume; the next till it is reduced one third; the thickest till it is reduced one half.

These directions are to be considered as very general ones; and the state of the varnish is best judged of during the burning, by taking out some with a spoon, and letting a drop fall on a cold earthenware plate, and trying its degree of viscidity with the finger. The thinnest sort should be like common honey, and the other should draw out in strings, which will be longer as the varnish is thicker. The thickest will draw out in strings two or three feet in length.

It is quite essential to have the oil pure, and the saucepan perfectly clean, and to keep the varnish in clean close jars in a cool place. It is best not to make the varnish long before it is wanted; for if any decomposition takes place in it, the drawing will be spoiled by the printing ink. The black is mixed with the varnish on a grinding stone with a muller, in small successive quantities; care being taken that the first portion of black is equally mixed with the varnish before a second is added. In the thickest inks this requires considerable labour. By mixing the varnishes together, any degree of stiffness of the ink may be obtained; and by putting more or less black, its thickness is regulated. The printer must always have by him several small pots, each containing a different printing ink, to be used as occasion requires. A small quantity, not more than the size of a hazel-nut, should be used at a time; for it is desirable to charge the roller with as small a quantity as possible. It must be worked well on the colour table with the roller in all directions, that it may be equally distributed all over the roller. Ink drawings are generally printed with a stiffer ink than chalk drawings.

6. *Preparation of the Stone for Printing.*

Etching.

The drawing being finished on the stone as before described, is sent to the lithographic printer, on whose knowledge of his art the success of the impressions in a great measure depends. The first process is to etch the drawing, as it is called. This is done by placing the stone obliquely on one edge over a trough, and pouring over it nitric acid very much diluted. It is poured on the upper part of the stone, and runs down all over the surface. The stone is then turned, and placed on the opposite edge, and the etching water, being collected from the trough, is again poured over it in the same manner. The degree of strength, which is little more than one per cent. of acid, should be such as to produce a very slight effervescence; after the etching water has lain on the stone for a second or two, its strength must vary according to the heat of the atmosphere and the degree of fineness of the drawing. It is desirable to pass the etching water two or three times over the darkest parts of the drawing, as they require more etching than the lighter tints; and when the drawing is fine, a little green should be mixed with it. Some stones also, and different chalks, require different degrees of strength of the acid; and experience alone can guide the lithographer in his practice on this point. Chalk drawings require weaker acid than the ink.

The stone is now carefully washed, by pouring clean rain-water over it, and afterwards with gum-water; and when not too wet, the roller, charged with printing ink, is rolled over it in both directions, viz. sideways, and from top to bottom, till the drawing takes the ink. It is then well covered over with a solution of gum-arabic in water, of about the consistency of oil. This is allowed to dry, and preserves the drawing from any alteration, as the lines cannot spread, in consequence of the pores of the stone being filled with the gum. After the etching, it is desirable to leave the stone for a day, and best not to leave it more than a week, before it is printed from. In some establishments a few proofs are taken immediately after the drawing is etched, but it is better not to do so.

The operation of the etching requires great nicety, and must be done quickly. If the drawing is etched too strongly, the fine tints disappear; if too weak, the printing ink mixes with the darker parts, and the drawing runs into blots. A soft stone requires weaker acid than a hard one, if they are equally pure in quality. The differences in the composition of the stones also require differences in the strength of the etching water, so that no strict or certain rules can be given.

The effect of the etching is, *first*, to take away the alkali mixed with the drawing chalk or ink, which would make the drawing liable to be affected by the water; and, *secondly*, to make the stone refuse more decidedly to take any grease. The gum assists in this latter purpose, and is quite essential to the perfect preparation of the surface of the stone.

7. *Printing.*

Printing.

When the stone is to be printed from, it is placed on the bed or platten of the press; at this time a proper sized scraper for the printing is very carefully adjusted to the surface of the stone. The gum on the stone is now sprinkled with rain-water, and being gradually dissolved, and a wet sponge passed lightly all over it, the printer works the ink which is on the colour table placed beside him, with the roller, in all directions, till it is equally and thinly spread all over the roller. He then, the stone being wet, passes the roller all over the stone in both directions, observing, as his experience enables him to do, that all parts of the drawing take the ink in due proportion. The roller should be applied with an equal motion and pressure, which must be regulated according to the mode in which the drawing takes the ink; if it does not take it readily, the pressure must be increased, and the roller moved more slowly. The roller should turn freely as it passes over the stone; if it slips, the cause is either that the stone is too wet, or that too much of the gum remains upon the stone; in the first case, a drier sponge will correct the evil; in the second, the stone must be again washed with a little water; but this must be done with caution, as the gum should not be entirely washed off the stone.

At first the drawing receives the ink with some difficulty, and it is frequently necessary to wet the stone and roll it in several times, before it will take the ink readily. Care must now be taken not to wet the stone too much; the less dampness the better, provided it is sufficient to keep the stone from taking the ink in the parts where there is no drawing; at all events, no drops of water should be seen upon the stone, as they spoil the printing ink, and also are imbibed by the roller, which therefore becomes unfit for use. After the drawing is thus rolled in, the sheet of paper is placed on the stone, and the impression taken in the manner described in the account of the press. When, after the impression, the paper is taken up, the stone appears dry, the moisture having been imbibed by the paper. It must be again wetted with a damp sponge, and rolled in with ink as before, taking care to work the roller well on the colour table each time before applying it to the stone.

Generally the first few impressions are imperfect, from the drawing not taking the ink fully; but this is gradually corrected in the succeeding impressions.

During the printing some gum must always remain on the stone, though it will not be visible, otherwise the ink will take on the stone, and also spoil the drawing. If, by too much wetting, or by rubbing too hard with the sponge, the gum is entirely removed, some fresh gum-water must be laid on. If the stone has, in the first instance, been laid by with too small a quantity of gum, and the ink stains the stone on being first applied to it, gum-water must then be used to damp the stone instead of pure water. Sometimes, however, this may arise from the printing ink being too thin, as will appear below. If some spots on the stone take the printing ink, notwithstanding the above precautions, some strong acid must be applied to them with a brush; and after this is washed off, a little gum-water is dropped on the place. A steel point is here frequently necessary to take off the spots of ink. The edges of the stone are very apt to soil, and generally require to be wiped with an old sponge or rag after the rolling in. They must also frequently have an application of acid and gum, and sometimes be rubbed with pumice-stone. Chalk drawings are much the most difficult to print. After this general description of the printing, the following development of the principles on which it is regulated, and notice of the difficulties which arise in its progress, will be found useful. *An ink which is too thin*, and formed of a varnish not sufficiently burned, will soil the stone, notwithstanding that the proper precautions are taken of wetting the stone, and preparing it properly with acid and gum. *Ink which is too stiff* will tear up the lighter tints of the chalk from the stone, and thus destroy the drawing.

The consideration of these circumstances leads us at once to the principles of the printing. These accidents arise at the extreme points of the scale at which the printing inks can be used; for it is evident, that the only inks which can be employed are those which are between these points, that is, thicker than that which soils the stone, and at the same time thinner than that which takes up the drawing. Any increase of temperature will diminish the consistency of the printing ink; the stone will therefore soil with an ink which could be safely used at a lower temperature; hence a stiffer ink must be used. Now, if the temperature should increase so much that the stone will soil with any ink at all less thick than that which will take up the drawing, it is evident that the printing must cease till, by standing, the lines of the drawing shall have acquired additional strength. This, though it sometimes occurs, is a rare case; but it shows that it is desirable to draw with a chalk or ink of less fatness in summer than in winter; and also, that if the printing-room is in winter artificially heated, pains should be taken to regulate the heat as equally as possible.

We will now enumerate some other difficulties which are not referrible to the above general principle.

If the pressure of the scraper is too weak, the ink will not be given off to the paper in the impression, although the drawing has been properly charged with it. Defects will also appear from the scraper being notched, or not correctly adjusted, or from any unevenness in the leather or paper.

Inequalities in the roller will cause the drawing to receive the ink unequally, and if the roller or its leather is too hard, it will not ink the drawing clearly.

After printing a considerable number of impressions, it sometimes happens that the drawing takes the ink in dark spots in different parts. This arises from the printing ink becoming too strongly united with the chalk or ink of the drawing, and if the printing is continued the drawing will be spoiled. A little consideration will show us the reason of this accident. The printing ink readily unites with the drawing, and being of a thinner consistency, it will by repeated applications accumulate on the lines of the drawing, soften them, and make them spread. In this case it is necessary to stop the printing, and let the stone rest for a day or two, for the drawing to recover its proper degree of hardness. If the drawing should run smutty from any of the causes before enumerated, the following mixture will clean it.

Mi ture to ean th drawin while pr ting.

Take equal parts of water, spirits of turpentine, and oil of olives, and shake them well together in a glass phial, until the mixture froths; wet the stone, and throw this froth upon it, and rub it gently with a sponge. The printing ink will be dissolved, and the whole drawing also will disappear, though, on a close examination, it can be distinguished in faint white lines. On rolling in again with printing ink, the drawing will gradually re-appear as clear as at first.

B ched pa r unfit fo ithogr hy.

Accidents sometimes occur in the printing, from the qualities of the paper. If the paper has been made from rags which have been bleached with oxymuriatic acid, the drawing will be incurably spoiled after thirty impressions. Chinese paper has sometimes a strong taste of alum; this is so fatal as to sometimes to spoil the drawing after the first impression.

Printing ink.

When the stone is to be laid by after printing, in order that it may be used again at a future period, the drawing must be rolled in with a *preserving ink*, called by Senefelder, *aetzfarbe*, as the printing inks would, when dry, become so hard, that the drawing would not take fresh printing ink freely. The following is the composition of the preserving ink.

Thick varnish of linseed oil	2 parts.
Tallow	4 do.
Venetian turpentine	1 do.
Wax	1 do.

These must be melted together, and then four parts of lamp-black very carefully and gradually mixed with it, and it must be preserved for use in a close tin box.

Very fine effects are produced in lithographic prints, by printing from two or more stones with different coloured inks. This is managed by preparing a composition of

Wax	2 parts.
Soap	1 do.
A little vermilion.	

Melt them in a saucepan, and cast them into sticks. This must be rubbed up with a little water to the thickness of cream, and then applied to the surface of a polished stone. An impression is taken in the common way from a drawing, and applied to a stone prepared in this manner, and passed through the press, care being taken to mark, by means of this impression, two points in the margin corresponding on each of the stones. The artist having thus on the second stone an impression from the first drawing to guide him, scrapes away the parts which he wishes to remain white in the finished impression. The stone must now be etched with acid stronger than the common etching water, having one part of acid to twenty of water. The whole is then washed off with turpentine.

This plan has been very much followed at Munich, and in this country some splendid specimens have lately been produced. It is generally used to print a middle tint from the second stone. The black impression being given from the first stone, a flat transparent brownish tint is given from the second, and the white lights are where the paper is left untouched. The dots are necessary to regulate the placing of the paper on the corresponding parts of the two stones.

The coloured inks for the tints are differently made, according to the tint required, but the varnishes alone make very good light browns.

The paper for lithographic printing should not be so damp as for copperplate printing.

8. *Different manners of Lithography.*

Besides the manners already described of drawing with ink and chalk, lithography is practised in various other ways.

Transfers.

Transfers.

The most useful of these is the transfer before alluded to in speaking of the inks, as it saves the labour and inconvenience of writing backwards. This is performed by writing with the composition ink on a prepared paper, and then transferring the writing to a stone, by passing it through the press.

Tints.

Dissolve in some water half an ounce of gum-tragacanth, to which, after it is well mixed and strained, add one ounce of glue and half an ounce of gamboge.

Then take of French chalk	4 ounces.
old plaster of Paris	½ ditto.
starch	1 ditto.

Powder these, and sift them through a fine sieve; grind them with a portion of the gum-tragacanth, glue, and gamboge; then add sufficient water to give it the consistency of oil, and apply it with a brush to thin sized paper. The writing must be made with the ink on the prepared side.

When the transfer is to be made, a polished stone is warmed to about 130° Fahrenheit, and placed in the press. The paper is then carefully damped at the back with a sponge, and placed between some sheets of soft paper. It is next placed on the stone with the writing towards it, and passed through the press as in printing an impression. This must be repeated four or five times without raising the leather cover of the bed of the press, beginning with a slight pressure at first, and increasing it every time. The press is now to be opened, and the paper, being damped, taken off, when the writing will appear to have come off the paper on the stone.

When the stone is quite cold, it is etched and prepared for printing in the usual manner.

This mode is peculiarly valuable for maps, plans, writings, &c. when expedition and economy are objects of importance; and the impressions produced by skilful lithographers retain all the purity and sharpness of the original drawing or writing.

Imitation of Wood Cuts.

Imitation of wood cuts.

This is a very easy mode, though not much practised. A polished stone is covered all over with lithographic ink, and the parts which are to be left white are scraped away with a steel point. Very fine lines are most easily obtained by putting them in with a hair pencil. The stone is etched as before described.

Etchings on Stone.

Lithographic etchings.

A polished stone is prepared for this mode by washing it with diluted acid as weak as the water used for etching a drawing; and after that is washed off, and the stone is dry, it is to be covered with weak gum-water and a little lamp-black. This forms a coating to the stone, and the artist works on it with an etching needle, as in etching upon copper. The lines which he traces appear white, but look stronger than they will appear afterwards. The stone should be a little warmed, for the needle to work freely through the coating, and care must be taken not to breathe upon it. When the etching is finished, the surface is to be rubbed all over with linseed oil, which penetrates into the lines drawn by the needle. After this the coating is to be all washed off with water.

In this mode lines can be drawn as fine as on copperplate; it is, however, but little practised in England, though it is often employed in Germany.

The great distinction between lithography and engraving, when employed for works of art, is, that the former gives a fac-simile of an original drawing, which retains all the freedom and touch of the artist's own hand; whilst, on the contrary, an engraving must be a copy. This character in a lithographic print arises from the facility with which the drawing is produced, as the process is exactly that which the artist would follow in making a common drawing: and the farther advantage of a great saving of expense is derived from the same cause; for the drawing being made at once on the stone, the whole expense of the engraving is saved. This is particularly the case with drawings in chalk, or with outlines or slight works in ink; and thus the door is opened to the production of many works which could not otherwise be published on account of the expense of engraving.

The more finished drawings in ink, however, have not the same advantages, for the gradations in tint can be obtained only by the variations in the breadth and distance of the lines, which is the same principle as that on which the engraver works; and hence the labour is more nearly equal in the two methods.

There is, however, much less difficulty in drawing lines on the stone than in cutting them on copper, and of course the operation is less expensive; and the cost of printing from stone is also considerably under that of printing from plates, which renders the employment of lithography doubly advantageous when a large number of copies are required. The number of impressions that may be taken from a chalk drawing varies according to the fineness of the tints and the manner in which the drawing has been executed. Some drawings will be exhausted by 1500 or 2000 copies, others have stood 20,000, and some even 30,000 impressions.

Ink drawings and writings give considerably more; the finest, if properly managed, will give from 6000 to 10,000; others it seems to be impossible to exhaust, hundreds of thousands having been printed from some without any material injury.

The advances which lithography has made within these few years have been really immense. Specimens in the chalk manner have been produced which vie in beauty with the stippled engravings in the line manner. Efforts equally wonderful have been made, and there seems no reason to doubt that further improvements will yet be effected in this infant art. The external delicacy of tint of the finest engravings there is reason to believe, as has already been shown, it never can equal; and it is more than probable that the station which it has already attained, is that which it is destined to fill; that is, betwixt the first class of engravings and the middling productions of copper and steel, its greatest advantages being economy and expedition in the execution. The innumerable instances in which the public have already been presented with valuable works by means of lithography, which could not have been produced by the more expensive and tedious mode of engraving, are sufficient evidences of its vast importance, and afford ground for the anticipation of still greater benefits.

LITHOMANTIA, in *Antiquity*, a species of divination performed with stones. Sometimes the stone called *siderites* was used. This they washed in spring-water in the night by candle light; and the person who consulted it was purified from all manner of pollution, and had his face covered. This being done, he repeated divine prayers, and having placed certain characters in an appointed order, the stone then moved of itself, and in a soft, gentle murmur, or, as some say, in a voice like that of a child, returned an answer. By a stone of this nature Helenus is reported to have foretold the destruction of Troy.

LITHONTRIPTICS (from *λιθος, a stone*, and *ϑρυπτω, to break*), an epithet applied to medicines that are supposed to break or dissolve the calculus in the bladder.

LITHOSTROTON, amongst the Romans, was a pavement of mosaic work, consisting of small pieces of cut marble of different kinds and colours, and first used in the time of Sylla, who caused one to be formed at Præneste, in the temple of Fortune, and afterwards in private houses. They were brought to such perfection, that they exhibited representations of nature with all the accuracy of the finest painting.

LITHOTOMY, in *Surgery*, the operation of cutting for the stone. See SURGERY.

LITHUANIA, an extensive province of Poland, now annexed to Russia. See the article RUSSIA.

LITINA, a circle of the Russian province of Podolia, extending in north latitude from 49. 5. to 49. 45., and in east longitude from 27. 45. to 28. 31. It is watered by the Bug, and has a rich and productive soil. The chief place, of the same name, is 1028 miles from St Petersburg. Long. 27. 4. E. Lat. 49. 19. N.

LITMUS, in the arts, is a blue pigment, formed from *archil*. It may be prepared by adding quicklime and putrified urine, or spirit of urine distilled from lime, to archil previously bruised by grinding. The mixture being cooled, and the fluid suffered to evaporate, becomes a mass of the consistence of a paste, and is laid on boards to dry in square lumps. It is only used in miniature paintings, but cannot be much depended on, because the least approach of acid changes it instantly from blue to red.

LITTER (*lectica*), a kind of vehicle borne upon shafts, anciently esteemed the most easy and genteel way of carriage. Du Cange derives the word from the barbarous Latin *lecteria*, straw or bedding for beasts; but others conceive that it comes from *lectus*, a bed. Pliny calls the litter the *traveller's chamber;* it was much in use amongst the Romans, and was borne by slaves kept for that purpose. The Roman *lectica* made to be borne by four men was called *tetraphorum;* that borne by six, *hexaphorum;* and that borne by eight, *octaphorum.* The invention of litters, according to Cicero, was due to the kings of Bithynia.

Litter also denotes a parcel of dry old straw put on the floor of a horse's stall, for him to lie down and rest upon.

LITTLETON, Sir Thomas, a judge of the common pleas, was the eldest son of Mr Thomas Westcote, of the county of Devon, by Elizabeth, sole heiress of Thomas Littleton of Frankley in Worcestershire, at whose request he took the name and arms of that family. He was educated at one of the universities, probably at Cambridge, and thence removed to the Inner Temple, where he became one of the readers. He was afterwards made steward or judge of the court of the palace, or marshalsea of the king's household, to Henry VI. In 1455, being the thirty-third of that reign, he was appointed king's sergeant, and travelled the northern circuit as judge of assize. In 1462, the second of Edward IV., he obtained a pardon from the crown; and, in 1466, was appointed one of the judges of the common pleas, and went the Northamptonshire circuit. In the year 1474 he was, with many of the first nobility, created knight of the bath. He died in 1481, and was buried in the cathedral church of Worcester, where a marble tomb, with a statue on it, was erected to his memory. As to his character as a lawyer, it is sufficient to state, that he was the author of the treatise upon tenures, on which Sir Edward Coke wrote a comment, well known by the title of *Coke upon Littleton.*

Littleton, *Adam*, descended from an ancient family in Shropshire, was born in 1627, educated at Westminster school, and entered at Oxford as a student of Christ Church, whence he was ejected by the parliamentary visitors in 1648. Soon afterwards he became usher of Westminster school, and in the year 1658 was made second master of that institution. After the Restoration he taught a school at Chelsea in Middlesex, and was admitted rector of the church of that place in the year 1664. In 1670 he obtained his degree in divinity, being then chaplain in ordinary to his majesty. In 1674 he became prebendary of Westminster, of which church he was afterwards sub-dean. Besides the well-known Latin and English Dictionary, he published several other works. He died in the year 1694, and was interred at Chelsea.

LITURGY denotes all the ceremonies in general belonging to divine service. The word comes from the Greek, λειτουϱγια, *service, public ministry*, formed from λειτος, *public*, and ἐϱγον, *work*. In a more restricted signification, liturgy is used amongst the Roman Catholics to signify the mass, and amongst the Episcopalians it is used to signify the common prayer.

In the primitive days divine service was exceedingly simple, being clogged with but few ceremonies, and consisting of only a small number of prayers; but by degrees the number of external ceremonies was increased, and new prayers were added, to make the office look more venerable to the people. At length things were carried to such a pitch, that regulation became necessary; it was found proper to put the service, and the manner of performing it, into writing; and this was what was called a *liturgy.*

In the early ages of the church every bishop had the power to form a liturgy for his own diocese; and if he kept to the analogy of faith and doctrine, all circumstances were left to his own discretion. Afterwards the practice was for the whole province to follow the metropolitan church, which also became the general rule of the church; and this Lindwood acknowledges to be the common law of the church, intimating, that the use of several services in the same province, which was the case in England, had no warrant except by long custom.

The liturgy of the church of England was composed in the year 1547, and established in the second year of Edward VI. (2 and 3 Edw. VI. cap. 1.) In the fifth year of this king it was reviewed, because some things were contained in that liturgy which showed a compliance with the superstition of the time, and various exceptions were taken against it by some learned men at home, and by Calvin abroad. Certain alterations were made in it, which consisted in adding the general confession and absolution, and the communion to begin with the ten commandments. The use of oil in confirmation and extreme unction was left out; prayers for souls departed, and what tended to a belief of Christ's real presence in the eucharist, were also omitted. This liturgy, so reformed, was established by the act 5 and 6 Edward VI. cap. 1. But it was abolished by Queen Mary, who enacted that the service should stand as it was most commonly used in the last year of the reign of Henry VIII. The liturgy of 5 and 6 Edward VI., however, was re-established with some few alterations and additions by 1 Elizabeth, cap. 2. Some further alterations were introduced, in consequence of the review of the common-prayer book, by order of James I. in the first year of his reign, particularly in the office of private baptism, in several rubrics, and other passages, with the addition of five or six new prayers and thanksgivings, and all that part of the catechism which contains the doctrine of the sacraments. The book of common prayer, so altered, remained in force from the first year of James I. till the fourteenth of Charles II. The last review of the liturgy was made in the year 1661, and the last act of uniformity enjoining the observance of it is 13 and 14 Car. II. cap. 4.

LITUUS, amongst the Romans, was the staff made use of by the augurs in quartering the heavens. It was crooked at one end, and thickest in the curved part, according to Aulus Gellius. Upon medals we frequently meet with a representation of it, amongst other pontifical instruments. It was called *Lituus Quirinalis,* from Quirinus, a name of Romulus.

Lituus was also an instrument of music in use in the Roman army. It was straight, excepting that it had a little bending at the upper end, like a lituus or sacred staff of the augurs; and from the similitude it derived its name.

LIVADIA, an ancient town of Turkey in Europe, and capital of a province of the same name in Greece. It is a large and populous place, situated on the Gulf of Lepanto, about twenty-five miles from the city of that name. It has now a considerable trade in woollen stuffs and rice. Anciently it was celebrated for the oracle of Trophonius, which inhabited a cavern in a hill above the town. Long. 23. 29. E. Lat. 38. 40. N.

LIVER. See Anatomy

LIVERPOOL.

Liverpool.

This town, which, after London, is the most considerable place of commerce in the British empire, or perhaps in the world, is situated in the hundred of West Derby, on the eastern bank of the river Mersey, in 53° 22′ 30″ of north latitude, and 2° 57′ of longitude west from Greenwich, at a distance of 30 miles west of Manchester, and 205 miles north-west of London. The town is bounded on the west by the river Mersey, on the east by Low Hill and Everton, on the north by the township of Kirkdale, and on the south by Toxteth Park.

The limits of the ancient borough were defined by marks called mere-stones, within which its liberties were included. It occupied an area of 2202 acres, of which about 1000 belonged to the Corporation, and the rest to individuals; but under the Parliamentary and Municipal Reform Acts, the limits of the present borough have been greatly extended, and now include a large part of Toxteth Park, Edge Hill, Low Hill, West Derby, Everton, and Kirkdale.

History.

The name of this place has given rise to much discussion. The most ancient record in which it is mentioned, is the charter of Henry II., where it is called Lyrpul or Litherpul, either of which is inconsistent with the fanciful derivation from the heraldic bird called the liver. It seems to be agreed that the latter part of the name designates a *pullum*, or pool of water; and Camden, who gives a Saxon derivation, explains only the termination.[1] But as the name *Lyferpole* does not rest upon any Saxon authority, its correctness may be questioned. To account for the more ancient orthography, however, it has been supposed that the name *Litherpool* was formed of the words *lithe pol*, signifying gentle lake. In an assessment of Lancashire, made in 1245, when Lancaster was charged thirteen merks, and Preston fifteen, Liverpool paid only eleven. In Leland's account of his journey, made about the years 1515 and 1516, we find this passage: "Lyrpole, or Lyrpoole, is a pavid towne, hath but a chapel, Walton a iv miles of, not far from the se is paroche chirch. The king hath a castlet there, and the Erle of Darbe hath a stone house there. Irisch marchants cum much thither as to a good haven. At Lyrpole is smaule custom payid, that causith marchants to resort. Good marchundise at Lyrpole, and much Irisch yarn that Manchester men do by ther."

A charter was granted to this town by King John in 1203, and renewed by Henry III. in 1228, by which he constituted Leverpolle a free borough. In 1272 a census was taken of the town, when it was found to consist of 168 houses, and occupied by about 800 inhabitants. Some records of the year 1555 represent it as a poor and obscure place, having only 138 householders and cottagers; but six years afterwards, the number of vessels belonging to the port were twelve, of 177 tons, and manned by 175 seamen.

In 1626 Charles I. granted a new charter, by which a corporate and politic body was created. At the levy of ship-money, in the early part of that reign, this town was assessed for L.25, whilst Chester was rated at L.26, and Bristol at L.1000, which may be some guide to the relative importance of the several places. During the civil war, in the latter part of this reign, it was the scene of several conflicts between the royalists and the parliamentarians; and, after a siege, when it was taken by the former, it suffered severely by the plague, which carried off 200 of its inhabitants. About this time, the ships in Liverpool and the dependent ports had increased as follows:—

Liverpool. . ships, 24 . . tons, 462 . . men, 76.

After the restoration, and the internal national peace that followed it, Liverpool seems gradually to have gone on increasing in extent, population, and trade. It appears that, in 1753, there were 3700 houses, and 20,000 inhabitants; and that in 1760, the houses were 4200, and the population 25,000. Dr Enfield, to whom we are indebted for these two comparative statements, does not give any data that can be implicitly confided in, but they have every appearance of approximating to accuracy.

Till the year 1698, Liverpool was included in Walton parish, but in that year it was separated from it. In 1699 it became an independent parish. The first newspaper was established in the year 1756; and in the year 1760, the first stage-coach was established between Liverpool and London. In 1770, the public library commenced, and about the same time the Society of Artists of Liverpool was founded.

The African and West India trade had been rapidly growing during seventy years, and all other branches had also been increasing. In the year 1754, there were

83 ships in the African trade.
124 ... in the West India trade.
28 ... in the American and foreign trade.
21 ... in the London cheese trade.
101 coasters and Irish traders.
80 sloops and flats on the river.

At this time a new dock was constructed, and received the name of the Salt-house Dock.[2] From that period, the progress of Liverpool has been truly without example in any other British port, or perhaps in any other age or country.

Antiquities.

On the site of St George's Church, formerly stood the ancient castle of Liverpool. According to Camden, it was built as early as the year 1076. Whatever may have been its origin, it was demolished by order of Parliament in the year 1659; but it existed in a dilapidated state from that time till the year 1721, when it was razed to the ground. There was also a building denominated the Tower, which occupied a site of about 3700 square yards, and was situated near the bottom of Water Street. It served for ages as the residence of the Earls of Derby, then as an assembly-room, and afterwards as a prison. It was demolished in 1819, and with it disappeared the last remaining vestige of the ancient days of Liverpool.

Population.

The state to which Liverpool has arrived, and the gradual steps by which it has been accomplished, within the present century, may be most accurately shewn by the returns obtained in the four decennial enumerations of Great Britain, which, by the diligence and acuteness of Mr Rickman, have been collected, arranged, and presented to the two houses of parliament. Every ten years exhibits more fully the state of the country than was to be found in the volumes that preceded it.

Population of Liverpool, including that of Toxteth Park.

---

[1] Ubi *Litherpoole* floret, Saxonice *Lyferpole*, vulgo Lirpool, a diffusa paludis in modum aqua, ut opinio est, nominatus. Camden *Britan.* p. 614. 1590, 8vo.

[2] The first dock constructed was the Old Dock, as it is called, which had been formed in 1699.

In the last of these years, the families were 38,122, of whom 227 were chiefly employed in agriculture; 18,881 were principally employed in trade, manufactures, or handicraft; and 19,014 were not comprehended in either of the before-mentioned classes.

The number of males who had attained the age of twenty years was 44,726. Of these, the portion employed in agriculture were, 39 occupiers of land, employing labourers; 165 occupiers of land, not employing labourers; and 132 employed as labourers in agriculture. The remainder are thus classed: 359 making manufacturing machinery; 21,208 employed in retail trade, or in handicraft, as masters or as workmen; 5201 capitalists, bankers, professional and other educated men; 16,095 labourers employed in labour not agricultural; 1214 others not particularly classed, and 313 domestic servants. The number of female servants was 9033.

Of the whole population, as before stated, of 189,242 individuals, the males were 87,919, and the females 101,323. The excess of the latter over the former may be attributed to the number of seafaring people, a part of whom must necessarily be much absent from their residences.

The rapid increase of the town will be observed from what has been stated; but the most authentic record of this increase is to be found in the bills of mortality, as preserved in the parish registers, and from them the following results are derived:—

	1700.	1760.	1800.	1810.	1820.	1830.	1834.
Baptisms,...	132	986	3033	4001	4718	7258	8154
Burials,......	124	599	3157	1544	3680	3845	5881
Marriages,..	35	408	1217	1434	1653	2220	2675

Exclusive of the baptisms, marriages, and burials in the places of public worship in Toxteth Park and Everton, and of the burials at the Necropolis, which, in 1834, amounted to 1586.

It appears by the bills of mortality that the increase of the population, as shewn by deducting the number of burials from the number of baptisms, would have been only 22,108 individuals in the ten years, from the year 1821 to the year 1831; whereas the returns shew an increase of 59,441; thus proving that besides the increase from itself, there must have been an immigration of 37,333 persons at Liverpool. The increased salubrity of the town is also observable. The whole of the burials in 1821 were 3267, out of a population of 131,801, or about one in forty; and in 1830 they were 3620, out of a population of 189,242, or one in fifty-two.

The increase in the population since 1830 has been remarkably steady, although the town has been twice visited by the cholera, and on one of the occasions very severely. The births in 1835 were 8145.

Docks. One of the main causes of the increase and prosperity of Liverpool has been the construction of the docks for the reception of ships. The river Mersey, on the right bank of which the town is built, empties itself through a great estuary filled with banks, and crossed by a bar at its mouth, which is very shallow at low-water; but the tides rise twenty-one feet at neap, and twenty-eight feet at spring-tides. The land around is low, and ships in the river are in consequence exposed to gales of wind. The entrance to the river is easy and safe, from some of the prominent objects on the peninsula which separates the Dee from the Mersey; and the nearer approach to the harbour has been facilitated by the construction of light-houses, by the erection of buildings called the Bootle-marks on the shore, by the establishment of floating-lights, and by an appropriate placing of buoys to mark the channel. The Mersey is navigable for vessels of sixty tons thirty-five miles above Liverpool, to the confluence of the Irwell. The river Weaver falls also into the estuary, and is navigable for vessels of sixty tons as far as Northwich, the great depository of rock-salt. It was to remedy the inconveniences felt after entering the harbour, that the docks here described were constructed. Between the town and the river, a tract of low land, nearly three miles in length, extending to low-water mark, was found adapted for the purpose of forming docks. The space thus recovered from the sea by persevering labour has been gradually converted into docks, containing 111 acres, and much of it is covered with warehouses and other buildings required by commerce.

Brunswick Dock. In the notices of the docks, we shall follow their position from south to north rather than the date of their construction. The southernmost of these is the Brunswick Dock. It is the largest of all, being chiefly constructed for the use of vessels employed in the timber trade. The east and west ends are 430 yards long, and the north and south 140 yards. It is connected with another, called the Half-Tide Basin, the dimensions of which are 120 by 108 yards.

Queen's Dock. The Queen's Dock, which is next to the Brunswick, has a communication with it by means of the Half-Tide Dock of the latter. It was opened in 1796, and is now chiefly frequented by vessels from the Baltic and from Holland. The mean length is about 400 yards, and the mean breadth about 100 yards. The gates are 42 feet wide, and 28 deep. At the south end, and the east and west sides, there are well-constructed sheds, affording shelter from the inclemency of the weather, whilst the cargoes are receiving or discharging. The quay is very extensive, and between it and the river are two graving-docks, 170 yards in length, admirably calculated for the building and repairing of ships.

King's Dock. The King's Dock, to the north of the Queen's and with an opening into it from a basin common to both, was first used in the year 1788. It extends from north to south 270 yards, and from east to west 95 yards. It is surrounded by spacious quays, with sheds for discharging tobacco, which constitutes the cargoes of most of the vessels that repair to it. The entrance, which is on the south side, has strong gates, 28 feet deep, and 42 wide, with a cast-iron bridge turning on a swivel. On the west side of this dock is one of the most capacious storehouses in the world, intended as the warehouse for bonded tobacco. It is a plain brick building, with walls eighteen inches in thickness, extending from north to south 575, and from east to west 239 feet; being in extent fifty per cent. more than the internal area of St Paul's cathedral in London, and containing three acres one rood and twenty perches. In this dock a vessel has been converted into a floating chapel, in which divine service is performed on Sundays. The pier on the west side forms a fine promenade, from which an extensive prospect over the river may be obtained.

Bridgewater Dock. The next dock, so called from the name of the constructor, the late Duke of Bridgewater, is small, but elegantly constructed. It has a range of storehouses upon an arch, under which vessels may enter and have their loading drawn up to the proper warehouses above them. This is private property, now belonging to Lord Francis Egerton, and used for purposes connected with his vast excavations and water communications on the Bridgewater canal.

Salthouse Dock. Nearest to the Bridgewater, and to the north of it, is the Salthouse Dock, which was opened in 1753. The form of this dock is irregular, being on the east side 297 yards, on the south end 80 yards, and on the north end 150 yards; the whole, with the passage, comprehending an area of 23,025 square yards. On the east side is a range of extensive warehouses, under the front of which is a piazza for the accommodation of passengers. The vessels which chiefly occupy this dock are those from the Levant, and the coasters from the neighbouring ports, and many from Ireland.

Dry Dock. The Dry Dock, next to the north, is also of an irregular figure. The west side is 150 yards in length, the north end 64 yards, the east side 219 yards, and the south end 108 yards. It has connected with it the graving docks, which are made use of for the purpose of building or repairing ships. The vessels which chiefly repair to this dock are those loaded with foreign corn, or employed in the coasting trade; the former generally load back with different kinds of foreign or colonial articles with which Liverpool is at all times well stored.

George's Dock. George's Dock, originally commenced in the year 1767, was repaired and considerably enlarged about ten years ago. It communicates at the south end with the Dry Dock by means of a canal 110 yards long, the gates of which are 25 feet long, 36 deep, and 42 wide. The dock is 246 yards long, and 100 broad, containing an area of 26,068 square yards. On the eastern side is a magnificent pile of warehouses, with an extensive piazza for the accommodation of foot passengers. The quay room around is spacious, and on the western side sheds are constructed to protect the goods, as they are landed, from the inclemencies of the weather. The basin belonging to this dock is at the north end, and its dimensions are, on the south side 163 yards, on the east and west sides 112 yards, and on the north side 154 yards. Within it is the Mariner's Church, in which divine service is weekly performed to the seamen.

Manchester Dock. To the south of the pier-head of this dock is a smaller one, the property of the Mersey and Irwell Company, called Manchester Dock, which is appropriated solely for the purpose of receiving the flats belonging to the company, which are loaded or discharged with their articles from the adjacent counties.

Prince's Dock. The most beautiful as well as the most stable of all the docks, is that called Prince's, which was begun in May 1816, and opened on the day of the coronation of King George IV., viz. on the 19th of July 1821. The length of the dock from north to south is 500 yards, and the average breadth from east to west is 110 yards, thus containing an area of 54,000 square yards. The total expense, as appears from official vouchers, was L.461,059 : 19 : 4, exclusive of the land, which is valued at L.100,000. At each end there is a dwelling-house, with appropriate offices, designed for the use of the dock-masters. There are two entrances; one from the George's Dock basin at the south, the gates of which are 45 feet wide, and 34 deep; and another at the north end, whose gates are of the same dimensions. Each of these passages is furnished with a lock, so contrived as to admit vessels either in or out at half-tide. The dock and its quays are inclosed with brick walls, having gates at the north and south ends, and on the east side. Between the western wall and the river is the Marine Parade, which is 700 yards long and 11 yards broad, and protected on the side next the water by a stone wall about a yard in height. There are also three flights of steps down to the river, for the convenience of passengers, who may land or embark in any state of the tide. When the tide is in, this forms a most varied and delightful promenade. The basin belonging to the Prince's Dock is situated at the northern end of it, and is 140 yards long, and about 134 wide at the centre, but differs a few feet at each end.

Clarence Docks. The newest, as well as the most northern of the docks, is that named the Clarence, in honour of William IV. It was first opened in September 1830. It consists of a principal dock, 250 yards long, 135 yards broad at the north end, and 111 yards at the south end, with a basin 160 yards by 100, between it and the river, furnished with gates, by means of which vessels may be allowed to pass either inward or outward at half-tide. The stone of which the walls are formed is of the most durable quality, and the masonry surpasses that of most works of the same description. On each side of the passage two beautiful circular offices have been erected, supplied with windows on all sides, through which a complete view may be obtained of every part of the dock and of the quays. A lofty and spacious shed extends the entire length of the eastern side, and the whole of these works is surrounded by a strong and lofty wall.

New Docks. Between the Clarence and the basin of the Prince's Dock, there are constructing three other wet docks, with an extensive graving dock, which is to be furnished with patent slips. One of them, the Waterloo Dock, is open to vessels, and requires only some additions to be made to the pier to complete it; the others are likely to be finished very shortly. They are to be called the Victoria and Trafalgar Docks.

The whole of these works are defended against the force of the powerful tides, which twice in twenty-four hours assail them, by a strong sea-wall more than two miles and a-half in length.

To this general description we are enabled to add, from an official paper, the following table, shewing the area of water contained in the stupendous excavations, and the quantity of quay-space which they afford :—

	Area of water in square yards.	Quay space in lineal yards.
DRY BASINS.

Half-tide Basin, . . .	9,245	483

This forms a total, of dock-room of one hundred and eleven acres, and the quay-space extends to nearly eight miles in length. The whole length of the river wall is about two miles and a half, exclusive of openings.

Proper precautions are adopted for clearing these docks from the mud, which every influx of the tide carries into them, and this purpose is effected by the aid of improved machinery, worked by steam. Strict rules are established and enforced as a guard against fire. No ship is allowed to have any gunpowder on board, nor any combustible articles on the deck. No fire is allowed in any ship, nor a candle to be lighted, except in a lantern, and these only to be used in the presence of a custom-house officer. The arrangements for admitting, or for the exit of vessels, and for their position when in dock, to forward their loading or discharging, are all well known and simple, and are executed under the authority of a dock-master, who is placed at the head of the officers of each dock, with proper persons under him to open and shut the gates at the proper time, and to execute such other business as may be required for facilitating the business to be transacted.

These extensive works have been accomplished by means of loans raised by the dock-trustees on bonds, for the payment of the principal and interest of which the rates are appropriated agreeably to an act of Parliament. When these bonds shall be discharged, or when the income is greater than the expenditure, the duties are to be reduced, so as to leave an amount equivalent to the expenses of the establishment, and to the necessary reparations. Such bonds are safe deposits for the savings of the inhabitants, and for the property of widows, orphans, or any trust-money; and thus great numbers in and around Liverpool are interested in the prosperity of these valuable works.

By means of these establishments, the cost in wear and tear of ships, and the expense of loading and unloading, is less at Liverpool than at most of the other ports of the kingdom. The celerity, also, with which every operation relating to the dispatch of ships is carried on, is greater than elsewhere, and thus an additional saving is effected in the wages and provisions for the masters and crews.

The warehousing or bonding system has tended very essentially to increase the commerce of Liverpool. The number of warehouses and vaults for bonded goods are very considerable, and there are a number of yards for bonded timber, as well as ample granaries under the King's Lock for foreign corn. The estimated value of bonded property is one million and a half Sterling.

Dock d
ies.

Our limits do not allow of tables to shew, for a series of years, the increase of the exports and imports of the various commodities which form the trade of Liverpool. The following table gives the amount of the dock duties received, and will shew the progress of its trade.

A Statement of the amount of Dock Duties received at the port of Liverpool for every 10*th year, ending the* 24*th June, from* 1752 *to* 1835, *both inclusive.*

Year.	Number of Vessels.	Tonnage.	Amount of Dock Duties. L.	s.	d.
1752	...	...	1,776	8	2
1762	1,307	...	2,526	19	6
1772	2,259	...	4,552	5	4
1782	2,496	...	4,249	6	3
1792	4,483	...	13,243	17	8
1802	4,781	510,691	28,192	9	10
1812	4,599	446,788	44,403	7	11
1822	8,136	892,902	102,403	17	4
1832	12,928	1,540,057	170,047	6	11
1833	12,964	1,590,461	182,980	16	4
1834	13,444	1,692,870	191,729	17	8
1835	13,941	1,768,426	198,637	18	9

This account includes not only what is paid for the space and the time which the vessels occupy, but also for the storage of goods in the several warehouses belonging to the docks. In fact, the dock duties and storage duties are about equal, but the latter somewhat exceed the former.

The following official tables will shew more distinctly the manner in which the dock estate is raised, and also the nature of some of the other principal charges to which the commerce of the port is subject.

A Comparative Statement of the Rates and Duties received in the years ending on the 24th of June 1834 *and* 1835.

The amount of the different duties, as stated above, for the present year (1836) is L. 244,814 : 5 : 9.

Dock
evenu

The dock estate is at present under the management of trustees, who give an annual statement of the receipts and payments. The trusteeship, after the 1st November 1836, by the Municipal Reform Act, falls again into the hands of the corporation of the town. From the printed accounts for the two years ending June 24, 1832 and 1833, we give the following abstract:—

	1832.			1833.		
Receipts,	L. 187,873	1	7	L. 201,376	10	11
Payments	303,545	11	7	173,678	1	7

General Statement of the Affairs of the Trustees of Dock up to June 24. 1833.

	In the hands of Treasurer, .	613	2	10
	By balances due in sundry open accounts, ...	22,317	15	4
	By amount of materials unexpended, ...	62,820	14	3
	By balance, ...	1,227,008	8	2
		L.1,353,157	2	10

The debt due by the trustees, 24th June 1833, was L.1,353,157. 2s. 10d., and the income on an average amounts to nearly L.180,000 per annum.

Trade and Commerce. The countries with which the extensive commerce from Liverpool is carried on, could be best exhibited by shewing the arrivals and departures of vessels in a series of years; but, as such accounts would be long, and to many uninteresting, one year is selected to shew in what proportion the arrivals have been from the various quarters of the globe. The year 1832 is selected because it was one of about an average trade.

An Account of the number of Ships that entered the Port of Liverpool in the year 1832.

Countries.	British.		Foreign.	
	Vessels	Tonnage.	Vessels.	Tonnage.

In order to shew the commercial importance of Liverpool in comparison with that of the other larger ports of this kingdom, the following statements are exhibited:—

Ports.	Number of Ships.	Tonnage.
London,................	2663	572,835
Newcastle,............	987	202,379
Liverpool,.............	805	161,780
Sunderland,...........	624	107,628
Whitehaven,..........	496	72,967
Hull,....................	579	72,248
Bristol,.................	316	49,535
Yarmouth,.............	585	44,134
Whitby,................	258	41,576

The following are the number of vessels, with their tonnage, which arrived in the years 1835 and 1836:—

Year.	Number of Vessels.	Tonnage.
1836,.......	14,959	1,947,613
1835,........	13,941	1,768,426
Increase,	1,018	179,187

As the business of the shipowner is not an accurate criterion of the commercial importance of places, neither is the amount of custom duties an actually certain standard. The imports of articles which are brought from one part of the United Kingdom to another, and consequently pay no duty, may cause an enormous trade, and be highly beneficial, but nothing of it would appear in the returns of the amount of duty collected at the custom-house. Although we exhibit the means of making comparative estimates, yet, in the case of Liverpool, the imports from Ireland must not be omitted to be recorded in taking a view of the state of its trade. It appears that their imports of agricultural products alone, consisting of live cattle, corn, flour, malt, bacon, pork, beef, hams, butter, hogs-lard, and eggs, amounted, in 1832, to L.4,444,500, 6s.; in 1833, to the estimated amount of L.8,179,844, exclusive of linen, feathers, hides, wool, and porter, to at least the value of L.50,000 of the latter article.

The quantity of Wheat sold in Liverpool from 1825 to 1834, is also given to shew its importance as a wheat market:

Quarters sold.

1825,	1826,	1827,	1828,	1829,

The Gross and Net Amount of the Duties collected at Liverpool Custom-House in the years ending 5th *January* 1834 *and* 1835.

	Gross Receipt.			Net Receipt.		
1834,...	L.3,733,166	8	10	L.3,540,472	14	1
1835,...	3,846,306	9	11	3,622,310	11	11

The salaries paid to the officers at the Custom-House for 1835, were L.46,447 : 18 : 0 ; and the incidental expenses amounted to L.47,541 : 3 : 7.

The vast extent of the commerce of Liverpool, as here in some measure exhibited, has in a great degree been indebted for its progress to the capital, the skill, and the industry of the inhabitants of the counties in its vicinity, as well as to the convenience of its port and its docks. With these counties the facilities of intercourse have been constantly advancing, chiefly by the numerous internal canals which branch out from the river Mersey. One of these, the Leeds and Liverpool, which brings Hull, by the Aire, in communication with the Mersey, forms a way for conveying the woollen and cotton goods made in the West Riding of Yorkshire to the great shipping port for America, where are the greatest number of the consumers of them. In the course of this canal, either by direct or indirect communication, it is brought in contact with the manufacturing towns of Wigan, Chorley, Preston, Bolton, Blackburn, and Rochdale, in Lancashire, and with Halifax, Huddersfield, Bradford, Leeds, Wakefield, Barnsley, and Sheffield, all towns of great manufacturing activity. By the Duke of Bridgewater's canal from Runcorn, Liverpool is brought into direct contact with Manchester and Stockport, and with that vast mass of coal on the duke's estate, which could easily supply the whole fuel for these and the surrounding populous places, but it is surprising how little of that valuable commodity comes down to Liverpool by the canal. By the Grand Trunk Canal, the Mersey is supplied with the rock and refined salt, both articles of very great export, from the towns of Middlewich and Northwich, in Cheshire ; and the cheese of that county is by the same channel brought to be shipped for London, and other ports of the southern divisions of the kingdom. The same canal passes Staffordshire, from the northern part of which the potteries of Burslem, and the large new built towns in its vicinity, convey thousands of crates of their ware annually, which are dispatched from Liverpool to all parts of the globe ; whilst, in its progress to the south, it touches Wolverhampton, the head-quarters of the heavy iron manufactory ; and then, by other canals to Birmingham, with its innumerable articles of hardwares of which every country in the world receives a portion. The canal navigation to the south joins the two great rivers, the Severn on the west, and by the Grand Junction with the Thames on the east ; and thus a water communication is maintained internally with almost every part of the south of the kingdom.

Corporation Revenues.

The annual revenue of the corporation in 1793 was L.25,000, which, valued as capital, was estimated at L.1,044,766. The debts due by the corporation were also valued and found to amount to L.367,816, 12s., leaving a balance in favour of the corporation of L.676,959, 8s. The revenues have, since that period, materially increased in value. The income is now about L.150,000 per annum, and the debt is upwards of a million.

The most abundant source of revenue to the corporation is in the town-dues,—a rate levied generally on all merchandise imported or exported into or out of Liverpool. Freemen are exempted from this tax. The following table shews the amount of the town-dues every tenth year from 1731 to 1831, each year ending 12th of October :—

1731 .	L.648 16 3	1791, .	L.10,440 11 2
1741 .	1,163 9 2	1801, .	19,728 3 5
1751 .	1,338 1 5	1811, .	21,418 5 3
1761 .	2,162 7 10	1821, .	33,090 5 6
1771 .	2,899 11 8	1831, .	35,176 12 6
1781 .	4,479 15 8		

State of the Poor.

There are few towns which have their parochial concerns of such magnitude as Liverpool, or have the affairs connected with it better conducted.

The Workhouse, perhaps the largest in the kingdom, was erected in 1771, but has been much enlarged since that period. The paupers in it are well supplied with the necessaries of life, and the aged amongst them are allowed many additional comforts. All that are not sick are employed in some trade or useful manufacture, such as joiners, blacksmiths, wheel-wrights, shoemakers, tailors, &c., but their labour is not very productive. The boys are instructed in some trade, and the girls above nine years of age are taught to knit, sew or spin, to make straw bonnets, or to weave calicoes or other cloth.

The local taxes for this and other purposes, assessed and collected in Liverpool, are shewn by the following table, and clearly prove that neither pauperism nor taxation have increased in the same ratio as the population, and, it may be presumed, not in the same ratio as the wealth.

Table to shew the number of the Poor, their Maintenance, the annual Parochial Assessment, Rental, Receipts, Expenditure.

Year.	Number of Poor in the Work-house.	Whole cost of their maintenance.	Average weekly number of out-door Poor.	Whole cost of their maintenance.	Number of houses assessed.	Rates on the whole rental.	Amount of the rent of the houses.	Amount of the rates.	Amount received.	Expenditure.
1828	1411	L.10,259	1070	L.10,034	26,253	L.0 2 6	L.530,623	L.66,327	L.50,844	L.42,870
1829	1533	11,359	1291	11,793	27,023	0 2 0	548,218	54,821	42,127	43,582
1830	1606	14,288	1442	13,906	27,791	0 2 0	568,531	56,853	43,637	51,899
1831	1648	13,790	1635	14,922	30,320	0 1 9	695,759	60,879	45,788	51,725
1832	1715	13,971	1980	17,534	32,554	0 2 6	854,587	106,872	80,000	62,415
1833	1792	15,981	2083	18,624	33,032	0 2 1	790,515	82,367	61,200	58,980
1834	...	...	...	...	33,222	0 2 1	801,964	83,660	62,500	54,201

The valuations of the several premises were, in the years 1820, 1821, and 1822, about equal to the rack rent. From 1823 to 1830 they were about four-fifths of the rack rent, and from 1831 and 1834 they were nearly equal to the full value.

The proportion of these rates, which are actually collected, has varied in different years between 70 and 74 per cent. of the amount assessed.

Iunicip overn- ent.

The corporation, which is one of the most ancient and wealthy in the kingdom, has been altogether remodelled by the Muncipal Reform Bill. Previous to the passing of the act, the Body-Corporate consisted of forty-one persons, chosen by the freemen of the borough. These formed the common-council, and from amongst whom were chosen annually a mayor and two bailiffs : vacancies were filled up by the members of the council, as they occurred. By the Municipal Reform Act, the old corporation was abolished, and the town was divided into sixteen wards, returning forty-eight councillors and sixteen aldermen, who are to be elected on the 9th of November by the resident rate-payers. The councillors remain in office for three years. The mayor is elected from amongst themselves; the whole corporate body being thus sixty-four. They are required to meet quarterly, but they generally meet once a month, and often more frequently. The council is empowered to enact laws for the better regulation of the police of the town, of the port, and of the dock, as well as for watching and lighting of the town, and other public purposes.

Since the accession of the new council to office, a new and improved system of police has been formed; old laws have been consolidated; and preparations are now making to extend to the new extended borough, the advantages enjoyed by the inhabitants of the old. There are twenty-nine justices of the peace for the borough of Liverpool.

At the registration of 1836, the total number of persons qualified to vote for members of parliament was 10,600.

Adjoining districts.

The districts in immediate communication with Liverpool have within the last thirty years increased from 2,000,000 inhabitants to 3,600,000; and there can be no doubt but that their wealth has been augmented in a still greater ratio. It has, too, been brought into indirect communication with a much larger district, as the advance extends the limits of supply at every step on both sides its course. The increase of the import trade, or of foreign commodities, including colonial, is thus very naturally acounted for.

Markets.

The recent introduction of steam navigation has been extended amply to Liverpool, and been found of the greatest benefit. In the supply of the markets with every kind of provisions from the adjoining districts on the shore, but especially from Ireland, the accuracy of their arrival when loaded with perishable products, has had a manifest good effect in reducing their prices. Steam-boats are constantly passing between the Mersey and the ports of Ireland, of the Isle of Man, of Scotland, and of North Wales. They are used at the ferry to the city of Chester, and, in contrary winds, to tow vessels into or out of the river. The celebrated rail-road, with its steam-carriages, between Manchester and Liverpool, has given a wonderful impetus to communication. A particular account of this railroad will be given under the article Manchester.

No place can be better supplied, or at lower rates, with all the necessaries and comforts of life, than Liverpool. Water, one of the first of those necessaries, is furnished by two companies. It is raised by steam-engines to the due height, to convey it to the upper floors of the dwellings. They also supply large reservoirs and many tanks, in different parts, which have always abundance of water ready to extinguish fires.

It has been observed that the markets are well supplied; to which may be added, that they are well calculated for the display and preservation of the commodities, by the appropriate nature of the buildings. The most extensive market is St John's, containing an area of 8235 square yards, being 183 in length and 45 in breadth. It is very light and clean, and at night is lighted by gas. The roof is lofty, supported by cast-iron pillars, and against the walls are nearly sixty small shops, eighteen feet long, and twelve feet wide, with a fireplace in each. There are besides upwards of 500 stalls or compartments, allotted for the exhibition of vegetables, eggs, poultry, fish, fruit, and potatoes, and on the basement thirty convenient storehouses. The whole is supplied with pumps of hot and cold water, and every evening the floor is swept and washed, and then shut up under the care of watchmen. The regulations for weighing, or otherwise ascertaining the quantities of the articles sold, are simple and cheap; as are those for the regulation of the porters, who are known by a badge, and carry the purchases from the market to the residence of the buyers. It is perhaps the best and neatest market of any city in Europe. There are others. St James's market is neat, but has an area of only 3000 yards. At the end of the same street is a commodious fish-market, opened in 1826. A new market, with an elegant front, has been built in a situation convenient for those in the neighbourhood of Scotland Road; and besides these are Islington, Pownal Square, and Cleveland Square Markets; one for hay and cattle in Lime Street, and one for pigs in Great Howard Street. There is a market for live cattle three miles from the town on the London road.

Streets and Buildings.

The streets in the centre of the town are generally narrow, and rather gloomy in their appearance; but many of the recently-built portions are handsomely, and some elegantly arranged, and contain very excellent houses. There are abundance of good hotels and inns. The streets are well paved, and lighted with gas furnished by two companies; and the police, for the preservation of the peace and of cleanliness, is well arranged. The public buildings deserve notice. The first of these, in point of extent, is the Town-Hall, built on the site of a former one which was consumed by fire in 1795. It is of a quadrangular form, with a rustic basement, on which rises a range of columns and pilasters, having rich and finely-finished capitals. Between the pilasters are handsome well proportioned windows, with semicircular heads. On the western and southern sides the spaces between the capitals are ornamented with various designs, executed in bas-relief, emblematic of commerce. The whole is surmounted with a large and stately dome, in strict keeping with the rest of the building, and supporting a massive figure of Britannia in a sitting posture. The principal entrance is through a portico, which leads to a splendid staircase, illuminated from above in a manner to produce a highly pleasing effect. It is adorned by a fine white marble statue of the late Mr Canning, by Chantrey. The principal story is laid out in a fine saloon, two drawing-rooms, and a ball-room of great dimensions; and in the former are excellent portraits of his present Majesty William IV., when Duke of Clarence, by Shee; of George III., by Sir Thomas Lawrence; of George IV., when Prince of Wales, by Hopner; and of the late Duke of York, by Philips. The painting and other ornamental finishing of the apartments, as well as the furniture, are tasteful and appropriate, and executed at an expense becoming the liberality of the second commercial city of the world. The dome has a gallery surrounding it, whence a very fine view may be obtained of the whole of the river and docks, and of the country around.

This building forms one side of another mass of erections, executed about twenty-five years ago, for the purpose of an Exchange. It is of great extent, being 197 feet long and 178 broad, thus forming a quadrangle of 3500 square feet, being nearly double the space occupied by the area of the Royal Exchange in London. It has upon one side a finely-proportioned Doric front, with three rusticated arches, one forming the entrance to a large and splendid vestibule, composed of thirty-two columns, from which spring richly ornamented groined arches. The architectural beauty of this arcade attracts universal admiration. In the eastern wing is the new room 94 feet in length and 51 in width, in which are to be found the papers relating to knowledge in general, of either politics or commerce, that are issued in the several countries of the globe. Over this is another apartment, used by the insurance-brokers and underwriters, where insurances of shipping are effected. The rest of the building is used as offices, and the exterior consists of large and convenient warehouses.

In the centre of the area a splendid bronze monument to the memory of Lord Nelson was erected in 1813. It stands on a circular marble basement, at the top of which is the principal figure, in an erect attitude, receiving from Victory a fourth naval crown, whilst Death is aiming the fatal blow from under the folds of the enemy's flag, whilst a sailor is seen grasping a battle-axe about to revenge the death of a hero, and Britannia leaning on her spear, with laurels in her hand, seems overwhelmed with a sense of her loss, and apparently regardless of her glory. The pedestal is beautifully adorned with designs in bas-relief, descriptive of some of the admiral's great naval battles. The whole is a fine piece of workmanship, executed by Westmacott, from a design by Wyat, and the expense, about L. 9000, was collected by public subscription.

The Sessions-house is a fine building, with a front of 174 feet in length. Its architecture is a specimen of simple elegance, whilst the interior is skilfully contrived to form an excellent court of justice, with easy access, and appropriate places for the magistrates, council, attorneys, witnesses, jurors, and prisoners. It contains also convenient apartments for committees, and a gallery for auditors.

A new custom-house was begun to be erected in 1828, and is now nearly finished. It is a large and magnificent building of fine freestone, of the Ionic order of architecture. It is composed of three façades rising from a rusticated basement. The portico on the north front forms the principal entrance, and is 470 feet in length, and the wings from north to south are each 220 feet. When the interior is finished it will be one of the most convenient, as it now is one of the most splendid edifices in the kingdom; and the Excise-office will be removed to and occupy a part of it, which will give great facility to both the revenue departments, as well as to the merchants and masters of the trading vessels.

The Dock-office, the Public Baths, where cold, tepid, vapour, and sulphur baths are always ready; the Corn-exchange, where sales of grain are made; are all, as buildings and as conveniences, worthy of observation.

The whole town of Liverpool constitutes but one parish. The mother church, dedicated to St Nicholas, is said to be on a site with a chapel built at the time of the Norman Conquest, but to have been kept by repairs in a state for public worship till 1774, when it was rebuilt. It is chiefly to be noticed on account of an accident which happened to it in 1810. Whilst the bells were calling the congregation to the morning service, the tower fell down upon the body of the church. Few adults were yet seated, but the children of a charity school had entered when the tower fell. Twenty-eight persons were taken out from among the ruins, of whom twenty-three were dead, or expired soon afterwards, and seventeen were of the charity children. A new tower has since been erected, in the ornamental Gothic style, which is a fine object, 180 feet high, and furnished with a peal of twelve bells.

Besides this there are twenty-seven other churches, and two chapels, in the Docks, for the adherents of the established religion. Many of them are elegant, most of them recently erected, and all commodious and spacious. They are capable of seating from 1200 to 2000 persons each, and in most of them the free sittings bear a very great proportion to the whole of the seats. In one of these, St David's, the service is performed in the Welsh language.

If our limits allowed it, many of these would be entitled to elaborate descriptions, but it can only here be said that, in combination with their spires, they produce a very striking effect on the appearance of the place, whether looked at in walking the streets, or viewed from the gallery of the Town-Hall, or any similar height. Some other churches are now building or projecting.

The several classes who differ from the established religion have their respective places of public worship. The Roman Catholics have five chapels, one of them a handsome Gothic edifice in Hawk Street, and another, equally spacious and neat, in Seal Street; the remainder are less striking, and are attended chiefly by the Irish of the lower classes. There are two churches of the Scotch establishment, and two for seceders from it. The Wesleyan Methodists, including their several sections or subdivisions, have twelve places of worship; one in Pit Street is large and commodious, and furnished with an organ; another in Moss Street is spacious, with rows of seats one above another like a theatre. The others, though of somewhat less dimensions, are neat and clean. The Independents have five chapels, one of which, the largest, in Great George Street, is a very spacious building, capable of seating 2000 persons; and being very commodiously arranged, the galleries contain nearly 1000 children of a Sunday school. One of the other chapels belongs to the Welsh Independents. There are eight chapels belonging to the different sections of Anabaptists, three to Welsh Calvinists, two to Unitarians, one each to the Quakers, to the Sandemanians, and the Swedenborgeans, and the Jews have also a synagogue. There is also a place of public worship for converted Jews. Several of the places of worship have their separate burying-grounds, and most of them, like all the churches of the established religion, have charity schools, either on Sundays or week days, or both.

Very few of the churches have burying-grounds attached to them, but an extensive cemetery has been formed, with the chapel of St James's within it for reading the funeral service. The ground contains 44,000 square yards, and was originally the stone quarry from which much of the materials for the buildings of the town was drawn. It is laid out with taste, and kept in good order, and recently a handsome house has been erected for the officiating minister. There is another cemetery at Low Hill, which is open for the entombment of persons of every religious denomination.

Besides the institutions for communicating religious instruction, Liverpool is not deficient in others for the promotion of general knowledge, and the diffusion of a taste for the fine arts, and other objects which give grace to human society. One of these is the Liverpool Royal Institution in Colquit Street. It was first opened in 1817, with an appropriate address from that celebrated and estimable native of the town, the late William Roscoe. On the ground-floor there is an elegantly furnished reading-room, ornamented with several ancient paintings, formerly part of Mr Roscoe's collection, the production of the early masters, shewing the progress of the art to the commencement of the fifteenth century. The apartment is provided with a library, and most of the periodical works. In connexion with it is a lecture-room, 30 feet by 50, with seats for pupils in an ascending order. The upper stories are formed into a museum, containing collections of natural history, casts of the Elgin marbles, and of other Grecian antiquities, and a few specimens of statuary.

There are other institutions for the diffusion of knowledge, which may be noticed without entering into the minute details of their more peculiar objects. These are the School of Arts for the benefit of the artizans of the town; the Athenæum, a library of 14,000 volumes, with a news-room; the Lyceum, with a library of 30,000 volumes, and a spacious and elegant news-room; the Union News-room, with a select library, and an apartment used as a school of arts, in which lectures are delivered; the Apprentices' Library, and the Law Library, whose names designate the purposes to which they are applied. The Blue-coat Hospital was founded 125 years ago, and then maintained, taught, and clothed 40 boys and 10 girls, and the number is now increased to 350 of the two sexes. There are besides upwards of twenty free day-schools, mostly supported by bequests from, or subscriptions by, the members of the Established Church, and the children are instructed in the doctrines and worship adopted by it. One of these is a Welsh school, with 300 boys and 100 girls. The dissenters of every class are not behind their neighbours in providing means of education for the poorer members of their communion. The Wesleyan Methodists have more than 1000 children in the schools connected with their chapels, and the other sectaries display an equal degree of zeal, in proportion to their numbers, in this cause. There are six infant schools established, where those too young to receive much instruction are amused, kept from mischief, and are taught to acquire docility before they become prepared to enter the free schools.

The Infirmary is a public hospital, open to patients of every age, country, complexion, or creed. It is a fine building, capable of receiving 220 patients, if its funds were more ample than they are at present, of which the expectation is sanguinely indulged. There are two dispensaries, where advice from the ablest medical men can be obtained, and where medicines are supplied gratuitously every day. There are besides, a lunatic asylum, two ophthalmic institutions, an institution for relieving diseases of the ear, a marine humane society, an institution for teaching the deaf and dumb, a female penitentiary, and above all, the Blind Asylum, in which 120 beings are maintained and instructed, and occupied in such employments as are suitable to their melancholy condition.

Like other large towns, Liverpool has its places of amusement. The Theatre-Royal was built in 1772, and was enlarged in 1803. There is also an amphitheatre for equestrian and pantomimic performances, which open in some months of each year. A little but neat theatre has also been built in Church Street, for exhibiting dramatic pieces.

The Wellington Rooms, opened in 1816, are adapted for balls and for public dinners, or other social assemblies, having a ball, supper, and card room of elegant appearance, and tastefully furnished.

See Baine's Valuable History of Lancaster.

Liverpool, *Charles Jenkinson, first Earl of,* was the eldest son of Colonel Jenkinson, the representative of a family which had been settled at Walcot, near Charlbury, Oxfordshire, for above a century. Mr Jenkinson received his education at the Charter-house School, and at the University of Oxford. In early life he published verses on the death of Frederick prince of Wales, a dissertation on the establishment of a national and constitutional force in England, independently of a standing army, and a discourse on the conduct of government respecting neutral nations. In 1761, having obtained an introduction to the Earl of Bute, he became one of the under secretaries of state, and in the same year was returned to parliament for Cockermouth. In 1763, he was appointed joint secretary to the treasury, and having shared with Lord Bute the marked favour of his majesty George III. he, on that nobleman's sudden retirement from office, became a conspicuous member of the party then commonly called the King's Friends. On the accession to power of the Rockingham administration, in 1765, he resigned his public appointments; but about the same period he was nominated auditor of accounts to the Princess-dowager of Wales. In 1766 he was appointed a lord of the admiralty by the Grafton administration; and the following year he became a lord of the treasury. Under Lord North's government new honours awaited this steady aspirant for promotion. In 1772, he was appointed one of the vice-treasurers of Ireland; and, in 1775, he was allowed to purchase the patent office of clerkship of the pells in that country. He afterwards succeeded Lord Cadogan as master of the mint; and, in 1778, he became secretary at war. In 1783, he became a member of the Board of Trade; and, in 1785, he published his Collection of all the Treaties of Peace, Alliance, and Commerce, between Great Britain and other Powers, from the treaty of Munster in 1648 to the treaties signed at Paris in 1783. In 1786, he was made chancellor of the duchy of Lancaster; called up to the House of Lords by the style and title of Baron Hawkesbury of Hawkesbury, in the county of Gloucester; and appointed president of the Board of Trade. The commerce of the country formed a prominent object of attention to Lord Hawkesbury, and though his theoretical views were confined, his practical knowledge was extensive. He is said to have drawn up the commercial treaty with America, and to have facilitated the establishment of the South Sea fishery, to which he had been the first to direct the attention of the government. In 1796, his personal honours were carried *au comble* by his advancement to the dignity of Earl of Liverpool. His lordship was twice married, and had two sons and a daughter. After obtaining his earldom, he rarely quitted his retirement; but whenever he spoke in the House of Peers, the extent and accuracy of his information, particularly on commercial subjects, procured him marked attention. In 1805, he addressed a letter to the king on the coins of the realm, containing a concise and distinct statement of most of the facts deserving of notice in the history of British coinage. Lord Liverpool died on the 17th of December 1808. (A.)

Liverpool, *Robert Banks Jenkinson, second Earl of,* son of the preceding, was born on the 7th of June 1770. At an early age he was placed at an academy at Parson's Green, near Fulham, where he remained until his thirteenth year; he was then removed to the Charter-house School, where he continued between two and three years; and soon after leaving the Charter-house, he was entered as a student at Christ Church College, Oxford. Here he became acquainted with Mr Canning, the most distinguished of his contemporaries, and formed for him a friendship which proved of an unusually permanent character, and had more than once an important influence on the fortunes of Mr Canning's public life. About the period of the breaking out of the French revolution, Mr Jenkinson paid a visit to Paris, and was in that capital when the Bastille was demolished. This sudden ebullition of popular fury against one of the strongholds of tyranny, and some other excesses which he is said to have witnessed in the streets of Paris, appear to have excited in his mind apprehensions which clouded his judgment, and led him to form the most distorted and incorrect notions of the events which the progress of the revolution evolved in France. Soon after his return to England, he was introduced to parliament as one of the representatives of Rye, and took his seat under the avowed patronage of the minister, Mr Pitt. On the 27th of February 1792, he made his first speech, in opposition to certain resolutions proposed by Mr Whitbread, on the subject of the claim urged by the Czarina Catherine to the fortress of Ockzakow and the adjoining territory. His address was praised as manifesting considerable knowledge of the question in dispute, as well as of the affairs and prospects of Europe generally; and as the protégé of a powerful minister always finds indulgent critics, it was prognosticated that Mr Jenkinson would rise to be a distinguished parliamentary speaker, and an efficient member of the British cabinet. His next public appearance was one which reflects no honour on his memory. His father had been one of the opponents of the abolition of the slave-trade in the House of Commons; and the son was scarcely warm in his seat in the House of Commons, when he joined the ranks of those who, without venturing to defend the principle, sought to perpetuate the practice of this enormous iniquity. On the 2d of April 1792, Mr Wilberforce moved, in a committee of the whole house, " that the trade carried on by British subjects for the purpose of obtaining slaves on the coast of Africa, ought to be abolished." This was met by an insidious suggestion of Mr Dundas, who proposed to insert the word "gradually," before the word "abolished;" but Mr Jenkinson, whose zeal was too hot to be satisfied with mere evasion, moved "that the chairman should leave the chair." The amendment was, however, rejected by a large majority, and Mr Dundas's more adroit proposition agreed to. Never, perhaps, was so much splendid oratory displayed in the House of Commons, as in the debate which followed on Mr Wilberforce's motion.

Mr Jenkinson's next appearance was in a more prominent and less questionable position. The king of France had been deposed, and the British ambassador, Lord Gower, recalled. On the 15th of December 1792, Mr Fox moved an address to the king, praying that a minister might be sent to Paris to treat with the provisional government of France, touching such points as might be in discussion between his majesty and his allies, and the French nation. In the temporary absence of Mr Pitt, who had vacated his seat by accepting the wardenship of the Cinque Ports, Mr Jenkinson replied to Mr Fox, in a speech which, though warmly complimented by Burke, is more remarkable for rambling and vehement declamation, than any quality of a higher order. Mr Fox was much more effectually answered by an overwhelming majority. His motion was negatived without a division. In April 1793, Mr Jenkinson was appointed one of the commissioners of the India Board; and on the 6th of May he stood forward in opposition to Mr Grey's memorable motion on the subject of parliamentary reform, defending the state of the representation as it then stood, and maintaining that the House of Commons, constituted as it was, answered all the ends for which it had been designed. On the 6th March 1794, he opposed Mr Grey's motion for an address to the king, expressive of the concern of the House that his majesty should have formed an alliance with powers whose apparent aim was to regulate the affairs of a country with which they had no right to interfere. On the 10th of April, he undertook a more difficult task, namely, to justify the measures of the ministry, and to palliate the failure of the army commanded by the Duke of York at Dunkirk. Mr Jenkinson was long twitted in parliament and elsewhere, with an observation which fell from him on this occasion. He declared that "the marching to Paris was attainable and practicable; and that he, for one, would recommend such an expedition." The ridicule which this excited was unbounded; it became a stock topic of derision. "The conquest of France!" says Mr Fox, in his letter to the electors of Westminster. "Oh, calumniated crusaders, how rational and moderate were your objects! Oh, tame and feeble Cervantes, with what a timid pencil and faint colours have you painted the portrait of a disordered imagination!" Yet, such are the accidents of war and fortune, Mr Jenkinson, contrary to all human probability, lived to see his notion realized; and what seemed, in the year 1794, like a sick man's dream, or the vision of a disordered imagination, was effected in 1814, and repeated in little more than a year afterwards. On the 30th of May 1794, he made one of his best efforts, in opposition to Mr Fox's motion for putting an end to the war with France. This was perhaps the most active period of his life.

In the next session, Mr Jenkinson was absent from his place in parliament, love having superseded politics. On the 25th of March 1795, he married the third daughter of the Earl of Bristol and Bishop of Derry. At the opening of the session of 1796, the address was seconded by Mr Stewart, afterwards Lord Castlereagh, in the first speech delivered by him in the House of Commons. He was answered by Mr Sheridan, who strongly censured ministers, at the same time advising them to declare themselves willing to treat with the French republic. Mr Jenkinson replied to Mr Sheridan, repeating his former arguments in justification of the government measures. Upon commercial subjects Mr Jenkinson entered with confidence, conceiving, perhaps, that he had some claims to "hereditary knowledge." On Mr Grey's motion in the House of Commons (10th of March 1796) for an inquiry into the state of the nation, he descanted on the effect of the war upon our commerce, contending that, notwithstanding its pressure, the situation of Great Britain, in a commercial point of view, was more prosperous than at any preceding period. On the 28th of May 1796, Mr Jenkinson participated in the honours of his family, exchanging its surname for his father's second title of Lord Hawkesbury. When the great measure of the legislative union with Ireland was proposed, it received his entire concurrence. The subject was introduced by a message from the crown, on the 22d of January 1799; and, in the discussion which ensued, Lord Hawkesbury warmly supported the views of government respecting it.

The circumstances which attended the temporary retirement of Mr Pitt from power early in 1801, are too well known to render it necessary to say any thing respecting them. In the new ministry, the formation of which was announced on the 14th of March, with Mr Addington at its head, Lord Hawkesbury was appointed to the office of secretary of state for the foreign department, and took a prominent part in the debates which ensued. The great business of the succeeding summer and autumn consisted in the adjustment of preliminaries of peace with France. Lord Hawkesbury, as foreign secretary, was of course intrusted with the interests of Great Britain in the negotiations which followed the signature of the preliminaries; and, on the 28th of March 1802, a definitive treaty of peace was concluded at Amiens between the French republic, the king of Spain, and the Batavian republic, on the one hand, and the king of Great Britain and Ireland on the other. In the important debate on this peace, which took place on the 13th of May 1802, Lord Hawkesbury defended the treaty at great length, in a speech which was considered as the ablest that had been delivered in either house of parliament on the ministerial side. He also distinguished himself by the part he acted in reference to the remonstrances of the First Consul respecting the strictures made on his person and conduct by the newspaper press of Britain; and, in the correspondence which ensued with M. Otto, he ably vindicated the public character and liberties of his country. The evil complained of, though certainly calculated to keep alive national animosities, and to provoke a renewal of the war, was not one for which the government could afford any redress. The constitution of this country admits of no previous restraint upon publications of any description. But there exist judicatures, wholly independent of the executive government, capable of taking cognizance of such publications as the law deems to be criminal, not only of libels against the government and magistracy of this kingdom, but also of publications defamatory of those in whose hands the administration of foreign governments is placed To these the French minister was with strict constitutional propriety referred. For, as the government of this country neither enjoys nor requires any other protection than that which is afforded by the laws, it could never be expected to consent to new-model laws, or to change its constitution, in order to gratify the wishes of a foreign power. In October, Lord Hawkesbury, in his turn, remonstrated against the occupation of Switzerland by the French under Ney, in order to enforce the reception of a new constitution for that country, prepared by the First Consul in his own cabinet. This he did in a note addressed to M. Otto, in which he expressed the deep regret excited in the breast of his majesty by the proclamation of the First Consul to the Helvetic people, and declared that his majesty could view the recent exertions of the Swiss cantons in no other light than as the lawful efforts of a brave and generous people to recover their ancient laws and government, and to procure the re-establishment of a system not only favourable to their domestic happiness, but perfectly consistent with the tranquillity and security of other powers.

At this period, the management of the House of Commons had, in a great measure, devolved on Lord Hawkesbury, who, of course, spoke on every topic involving the character of the administration, as well as on the political questions which were brought under the consideration of the House of Commons. At the opening of next session, he was called to the House of Lords by writ, as a peer's eldest son; but the only measure of importance which in that session he brought forward in the new situation in the legislature where he had been placed to defend the measures of ministers, was the volunteer consolidation bill. About the same time, he addressed a circular to the ministers of foreign courts resident in London, disclaiming indignantly the charge that his majesty's government had been a party to plans of assassination, and describing the recent seizure and execution of the Duke d'Enghien as "a sanguinary deed, perpetrated by the direct order of the First Consul, in violation of the rights of nations, and in contempt of the most simple laws of humanity and honour." That the British government were innocent of the crime imputed to them, is beyond a doubt. But, on the other hand, it cannot be denied that the life of the First Consul had been openly attempted in the streets of Paris; that Pichegru, Cadondal, and their associates, avowedly meditated assassination; that these conspirators had been landed on the coast of France by an English vessel, commanded by an English captain; that the English press continued to revile in unmeasured terms the head of the French government, if not to insinuate that taking him off would be a meritorious act; and that, consequently, appearances unhappily seemed to give some ground to the charge which the First Consul preferred against the government of the country, in justification of a deed which, however it may be viewed, was, if not the greatest crime, at all events the greatest error, he ever committed.

On the 12th of May, the administration was dissolved, by the resignation of Mr Addington; Mr Pitt returned to the head of the ministry, and Lord Hawkesbury received the seals of the home department. The renewal of the war being now inevitable, the first effort of the new government was to place the military establishments of the country on a more enlarged and efficient footing; and with this view, Lord Hawkesbury exerted himself in the House of Lords in support of the additional force bill. At a later period of the session, Mr Wilberforce renewed his attempts to put an end to the detestable traffic in human flesh, and a bill for that purpose passed the House of Commons; but, on its transmission to the House of Peers, it was postponed, on the motion of Lord Hawkesbury, for more mature investigation in the ensuing session. The pretext was worthy of the cause in favour of which it was employed. On the 10th of May 1805, Lord Grenville moved the order of the day for taking into consideration the petitions of the Roman Catholics of Ireland. This motion Lord Hawkesbury also opposed. He would neither consent to break the fetters of the enslaved African, nor agree to remove the disabilities which placed millions of our fellow-subjects beyond the pale of the constitution. In the autumn of 1805, Mr Pitt retired to Bath, his health being then in a state of rapid decline. On the 11th of January 1806, he returned with difficulty to his house at Putney, where he died on the 23d, two days after the meeting of parliament. The death of Mr Pitt afforded Lord Hawkesbury an opportunity of placing himself at the head of the cabinet; but being well acquainted with the relative position and strength of parties, his ambition yielded to his good sense, and he declined the flattering offer. His majesty, however, appointed him to the situation of warden of the Cinque Ports, vacant by the death of Mr Pitt. On the return to power of that minister's friends in 1807, Lord Hawkesbury resumed his station in the cabinet as home secretary, and took a prominent part in defence of all the measures of government, particularly of the questionable expedition to Copenhagen, and the famous orders in council. Towards the close of 1808, Lord Hawkesbury was, by the death of his father, placed at the head of his family, as second Earl of Liverpool.

Lord Liverpool was the political heir of Mr Pitt, in all except his talents. Reposing a just confidence in the stability of our institutions, which had safely weathered the conflict with democratical principles, he adhered to the system of his early patron and master; and although Mr Pitt had died despairing of his country, Lord Liverpool was one of those who had the temerity or the courage to brave the concentrated power of imperial France, wielded by the most wonderful genius that any age or country has produced. True to the principle of eternal war with France, as long as a man sprung from the Revolution presided over her destinies, though the prospect was still dark, the immediate peril great, and the future shadowed out by portentous omens, he had still faith in the ultimate approach of a day of crowning triumph; and fortune at length smiled upon counsels which the ordinary inspirations of human wisdom had disclaimed. With these feelings, Lord Liverpool warmly advocated the cause of Spain, in the session which commenced on the 19th of January 1809. His doctrine was based upon the principle of tenacity. He contended that, according to all the lights furnished by history, nations, after maintaining such contests for ten or twenty years, have eventually succeeded, in spite of frequent and severe reverses, in securing the object which they struggled to attain. In a few days (23d January) he had occasion to move the thanks of the House of Peers to Lord Wellington for his conduct in the Peninsula. This motion especially related to the battle of Vimiero.

When the quarrel and subsequent duel between Lord Castlereagh and Mr Canning induced both to resign, and led the Duke of Portland to withdraw from his situation as nominal head of the administration, Mr Percival united in name, as he had already done in effect, the offices of first lord of the treasury and chancellor of the exchequer; and, in this new arrangement, Lord Liverpool became secretary of state for the war department. The illness of George III., the introduction of the regency bill, the difficulties which beset the prince regent in his endeavours to form a new administration, and his final determination to abide by Mr Percival, are all too well known to require any detail. In the two succeeding sessions the exertions of Lord Liverpool were unremitting, but not marked by any thing of prominent importance. At length, on the 11th of May 1812, Mr Percival fell by the hand of an assassin, leaving the ministry in so disjointed a state, that, after some abortive negotiations with the Marquis Wellesley and Lords Grey and Grenville, Lord Liverpool yielded to the request of the prince regent, that he would place himself at its head. The only additions made to the ministry upon this occasion were Lord Sidmouth, and Mr Vansittart, afterwards Lord Bexley.

The first important measure of Lord Liverpool's government was rendered necessary by the disturbances which had taken place in the manufacturing districts, where, owing to various causes, great distress prevailed; and it assumed the form of a bill to prevent the rioters from possessing themselves of arms, to guard against tumultuary meetings, and to give more extensive jurisdiction to the magistrates of the disturbed districts. Towards the close of the session, his lordship signalised himself by the explicit and unqualified opposition which he gave to a resolution proposed in the House of Lords by Marquis Wellesley, that the house would, early in the next session of parliament, take into consideration the state of the laws affecting the Roman Catholics. Upon this occasion the premier came boldly forward as the champion at once of injustice and intolerance. He would not consent that the question should be entertained in any shape, or that even so much as a hearing should be given to those who were suing to be relieved from the galling and ignominious stigma of bondage. He declared it to be a maxim of his political life, that, with respect to a great constitutional question, if a stand were to be made, it should be made *in limine;* and, in such a code of political morality as that which Lord Liverpool had espoused, there can be no doubt whatever that this is a maxim which Macchiavelli would have himself recommended as the only safe rule of conduct. When free scope is once allowed to formal inquiry, perseverance in injustice is no longer possible. On the 20th of September parliament was dissolved.

Meanwhile the transactions in Spain and the north of Europe were highly favourable to the cause of legitimacy. In the Peninsula, Ciudad Rodrigo and Badajoz had fallen; the victory of Salamanca had been followed by the advance of Lord Wellington on Madrid; the siege of Cadiz had been abandoned, and the whole south of Spain evacuated by the enemy. In the north of Europe events of a still more decisive character had occurred. The burning of Moscow, and the premature setting in of the frost, had sealed the doom of the French grand army; the former event had rendered retreat inevitable, and the latter soon converted that retreat into a scene of the most appalling horrors and disasters. What the fire had begun, the frost consummated; General Morosow did the work which General Kutusow could never have accomplished; and the Scythian wilderness was covered with the wrecks of that mighty host which had swept onwards in the proud confidence of superior power. These disasters became known in England during the bustle of the elections, and contributed to augment the public confidence in the war policy of ministers, which the elements had thus unexpectedly crowned with success.

The first session of the new parliament opened on the 28th of November 1812, and closed on the 22d of July 1813. The principal subjects brought under the notice of parliament were, the Marquis Wellesley's charge against the government, of not affording sufficient force to his brother; a proposition for granting relief to the Russians; an explanation of the causes of the rupture with America; the sinking-fund; the renewal of the East India Company's charter; and the treaty between Great Britain and Sweden; in the discussion of all which Lord Liverpool took part. The military campaign was one of still greater activity. Lord Wellington, after gaining the battle of Vittoria, taking San Sebastian, and blockading Pampluna, entered France, beat the French on their own ground, and fully established himself on the "sacred territory." In the north of Europe, where nations rather than armies assembled to combat the French, the campaign opened favourably for the allies; and the subsequent loss of the battle of Leipsig threatened the French emperor with utter ruin. The administration was duly sensible of the importance of the crisis. Parliament was assembled, principally to sanction loans of large amount to foreign powers; and before Christmas it was adjourned until the month of March. In the intoxication of victory, it was to the executive rather than to the legislative body that the eyes of the country were directed. The government had become omnipotent. The great events which followed were the entrance of the allies into Paris, the abdication of Napoleon, and the signature, on the 30th of May 1814, of a definitive treaty of peace between France and the allied powers. On the 24th of December a treaty was concluded at Ghent, which put an end to the unfortunate contest with America; and thus terminated a year as fortunate for Great Britain as any in her annals.

But the peace was destined to be short-lived. On the 20th of March 1815, Napoleon, having left Elba, landed in France, marched in a sort of triumphal procession to Paris, drove out the Bourbons, and replaced himself upon the throne, without firing a shot or spilling a single drop of blood. No sooner had intelligence of these astounding events been received, than messages were sent to parliament by the prince regent, and corresponding addresses moved by Lord Liverpool, who, in his speeches, dwelt much on the fortunate circumstance that Napoleon had undertaken his dangerous enterprise whilst the confederacy of the allies remained undisturbed, and they were still in a condition to act in concert. The result is universally known. Britain made gigantic efforts, both financial and military, to overthrow the man whom France had again placed at its head; and she was rewarded by the victory of Waterloo, where Napoleon drained the cup of misfortune to the very dregs. This was ere long followed by the treaty of Paris.

In the session of 1816 the principal subjects to which Lord Liverpool directed his attention were, the defence of the military establishment, explanations of the recent treaty, the transactions between government and the bank of England, and the state of the silver coinage. The meeting of parliament in 1817 was, from various causes, anticipated with much anxiety. The distress which prevailed amongst the manufacturers had produced disturbances in the inland counties, and a riot had occurred in the metropolis itself. The suspension of Habeas Corpus was proposed by the government; and Lord Liverpool had the unenviable task assigned him of defending that measure in the House of Peers. In seasons of distress, suffering naturally renders men credulous, and there are always persons ready to take advantage of this adjunct of misery; but there is too much reason to suspect that, in many instances, the starving people were first misled and afterwards betrayed by the agency of characters of a still more odious description, who were not altogether unknown to the government. The Catholic question having been brought under the consideration of the House of Lords on the 16th of May, by Lord Donoughmore, the premier restated his opinions concerning it, adding that "if the demands of the Catholics were complied with, the parliament would cease to be a protestant parliament." At a subsequent period of the session, ministers found it convenient to urge the continuance of the Habeas Corpus suspension act, which Lord Liverpool declared that he called upon parliament to vote, because "he considered the measure essential to the preservation of property and morality."

The death of George III. and the accession of George IV., who had already exercised the sovereign power for nearly eight years, made no change in the government, the ministers being immediately reinstated in their several offices. It is unnecessary to enter further into details, which more properly belong to the general history of the time. The principal affairs in which Lord Liverpool took a prominent and leading part were, the proceedings against Queen Caroline, particularly the bill of pains and penalties; the bill for the resumption of cash payments; the conduct of France and the allies in regard to constitutional Spain; the Catholic bill of 1825, with its two auxiliary measures, commonly termed "wings;" the state of the country, especially of the circulation, produced by the unexampled panic in the money market that followed the blind rage for speculation which distinguished the year 1825; the corn laws; and some other measures of less magnitude and importance. The Earl of Liverpool was in his place in the House of Lords on the 15th of February 1827, having brought down a message from the king recommending a provision for the Duke and Duchess of Clarence; and next day he moved an address expressive of the willingness of the house to comply with his majesty's request. This was the last occasion upon which his lordship appeared at his post. On the 17th he experienced an apoplectic attack, accompanied with paralysis, which at once prostrated both his mind and body; and, after lingering for a considerable time in a hopeless state, he expired in convulsive agony on the 4th of December 1828.

The public character of Lord Liverpool belongs to the history of that period, crowded with events of the greatest magnitude, during which he was either an influential member of the British government, or placed at its head; and he will be variously judged, according to the preconceived opinions of those who attempt to decide as to the character of that system of policy of which he was so long a prominent exponent. He was not a man of brilliant genius or excursive fancy, but he possessed useful talents, inflexible perseverance, and unimpeachable integrity, and towards the close of his life manifested a disposition to accommodate his policy to the advancing knowledge and opinions of the age. Excepting on a few points, he was perhaps the least bigoted and impracticable of the party which, after the death of Mr Pitt, recognised him as its head. As to his style of speaking, if it had little to recommend it in the form of eloquence, it commonly impressed the hearer with a conviction that the speaker was in earnest. He was vehement rather than energetic, and more noisy than forcible, but never intemperate. He entertained no angry feelings towards his parliamentary opponents; he never refused to others the tribute of applause which he thought they merited; and his gentlemanly deportment, unruffled by the rude collisions of party warfare, frequently disarmed his fiercest adversaries. In private life Lord Liverpool was justly respected for his amiable deportment and irreproachable conduct; sincere in his religious belief, and unobtrusive in the fulfilment of his duties as a member of society. We are far from entertaining any admiration of the principles of the minister, but it is a pleasing task to render homage to the virtues of the man. (A.)

LIVERY, in matters of dress and equipage, a certain colour and form of dress, by which noblemen and gentlemen choose to distinguish their servants. Liveries are usually taken from fancy, or continued in families by succession. The ancient cavaliers, at their tournaments, distinguished themselves by wearing the liveries of their mistresses. Thus people of quality make their domestics wear their livery. Father Menestrier, in his *Treatise of Carousals*, has given a very ample account of the mixtures of colours in liveries. Dion tells us that Œnomaus was the first who invented green and blue colours for the troops which, in the circus, were to represent land and sea fights. The Roman Catholic church has also her several colours and liveries; white, for confessors and virgins, and in times of rejoicing; black, for the dead; red, for the apostles and martyrs; blue or violet, for penitents; and green, in times of hope. Formerly, great men gave liveries to several who were not of their family or servants, in order to engage them in their quarrels for that year.

LIVERYMEN of London, are a number of men chosen from amongst the freemen of each company. Out of this body the common council, sheriff, and other superior officers for the government of the city, are elected; and until the passing of the reform act they alone had the privilege of giving their votes for members of parliament, from which the rest of the citizens were excluded. See LONDON.

LIVIUS, TITUS, the most celebrated of the Roman historians, was descended from an illustrious family which had given several consuls to Rome. Only a few particulars of his life have been transmitted to us. He was born at Patavium, now *Padua*, in the north of Italy, B. C. 59, the year before Cicero was driven into banishment; and died, at the advanced age of ninety-six, A. D. 18, the same year as Ovid. He resided during the greater part of his life at Rome; and, if we may credit a statement of Suetonius (*in Claud.* 41), became the instructor of the Emperor Claudius. His history was written partly at Rome and partly at Naples, and it is said that his reputation was so widely diffused, that a native of Gades, now *Cadiz*, in Spain, actually visited Rome for no other purpose than to have the pleasure of forming an acquaintance with the historian. (Plin. *Ep.* ii. 3.) From some inscriptions found at Padua in 1413, it has been asserted that Livy was twice married, had two sons and four daughters; but this must rest merely on conjecture, as there were no doubt many of the same name in Padua. Seneca (Procem. v. *Controv.*), indeed, states that one of his daughters was married to L. Magius the rhetorician.

Besides his history, we are acquainted with the titles of three other works of which he was the author; but not a fragment of them has been preserved. These were, *Epistola ad Filium scripta*, mentioned by Quintilian (i. 10); *Dialogi*, which Seneca (*Epist.* c.) hesitates whether he ought to class amongst historical or philosophical works; and *Libri ex professo Philosophiam continentes.* The loss, however, of these works, is less a subject of regret than that of the greater part of his *Roman History*, or, as he himself modestly entitles it, *Annals of the Roman people.* This work extends from the building of the city to the year 744 (B. C. 9), when Drusus was carrying on war in Germany, and in which he died. Livy undertook this work probably at the suggestion of Augustus, when he was already far advanced in years. It consisted of 142 books, of which only thirty-five remain; and some of these (lib. xli. xliii. xliv. xlv.) are in a very imperfect state. The first ten contain the history of Rome from its foundation to the year of the city 460, the others (xxi.–xlv.) from 536 to 586, or from the beginning of the second Punic war to the end of the wars with Perseus and Gentius. Of the remaining books we possess only short epitomes, which have been supposed, though without any sufficient reason, to have been composed by the writer Florus. It would appear that a complete copy of Livy's History existed at the beginning of the sixteenth century; but all attempts to discover it have hitherto proved unavailing. Some fragments have indeed been found, and published at Rome, by Niebuhr (1820); but they are few and unimportant. There is, indeed, no loss that has befallen us in Roman literature at all to be compared to that which has left this history imperfect.

Livy follows a chronological arrangement in his history, and, like Dionysius of Halicarnassus, has adopted the Catonian era for his basis. He therefore supposed the city of Rome to have been founded B. C. 751, whereas Varro placed it two years earlier, B. C. 753. The sources from which he derived his information, more particularly for the earlier parts of his history, seem less worthy of belief, though he probably had recourse to the best within his reach. All the more ancient historical records had no doubt disappeared, and he could therefore only be acquainted with their statements through the medium of later annalists. For this early period he had recourse to the works of no Greek historian, unless we include amongst them that of L. Cincius Alimentus, who, though a Roman, wrote in the Greek language. This author served in the second Punic war, and he is called by Livy (vii. 3) a most diligent investigator of ancient monuments. In the early part of the war he fell into the hands of Hannibal, and from him he received an account of his passage through Gaul and across the Alps, which he incorporated in his history. To the works of this writer Livy acknowledges himself much indebted. As to the sources from which he drew his materials for the second decade (xi.–xx.), which is lost, all that can be said is only matter of conjecture; but we know that Polybius was the principal writer whom he consulted, and that he followed that writer generally both in the arrangement of his materials and in the development of the story. It is not a sufficient answer to this that Livy seldom alludes to Polybius as his authority, since he does not think it necessary to cite the writer upon whom he depends for his information, unless on occasions where there is a difference of opinion. There is no doubt, that wherever he has adopted the statements of Polybius, we may place perfect confidence in the account; and yet, where they differ, we must not condemn Livy, who evidently consulted Roman authorities of undoubted credibility, and who may, upon due examination, have come to the conclusion that Polybius was mistaken. The difference in the accounts given by the two historians of Hannibal's passage across the Alps is an example of this, though the balance of probability is greatly in favour of that of Polybius.

Livy has been accused of a wilful perversion of the truth, of an undue partiality for his own country, and a desire to recommend himself to the favour of the nobility, by flattering their pride by the manner in which he records the deeds of their ancestors. But if he represents the characters of his countrymen in a different light from other writers, might he not suppose himself better able to appreciate their conduct? and if his love of country led him to conceal whatever might be prejudicial to them in the eyes of posterity, it was a fault for which he may be forgiven, though it certainly must be allowed to detract considerably from the value of his work. He has been accused also of superstition, because he has reported faithfully all the prodigies and omens in which those early ages abounded, and which seemed to have formed the principal part of their religion; but he has several times observed, that he narrates those wonderful events because he found them in the ancient annalists whom he consulted, without meaning to vouch for their accuracy. Livy was evidently gifted by nature with a brilliant talent for narration, and for seizing the characteristic features of humanity. He was a poet, though without the power or perhaps the love of versifying. His rhetorical powers, too, were of the highest order; and, in the palmy state of the republic, he would have ranked amongst the first orators of his age. The periods of Livy are full and well rounded, in imitation of the style of Cicero; and indeed the age in which he lived would have tolerated no other mode of writing. It is strange that there should be any difficulty in discovering the political sentiments of the historian; but he felt that he was writing under the eye of a despot, however amiable, and he thought himself obliged to suppress many sentiments to which he would in other circumstances have given utterance. He was fully sensible of the degeneracy of his own days, and was glad to forget it by reviving the recollection of all that was glorious and noble in the past. He might also imagine that he could excite in the breasts of his countrymen a desire to emulate the heroic deeds of their ancestors, and might thus be the means of restoring the constitution of his country to its ancient form and strength. It is said that Augustus accused him of being too favourable to the party of Pompey (Tacit. *Ann.* iv. 34); and we may therefore conclude that he was in his heart a partisan of the republic. It has been much disputed what Asinius Pollio (*Quintil.* viii. 1) meant by the accusation he brought against Livy of Patavinity (*Patavinitas*); but it seems the most likely conjecture that it was some provincialism in the language and style, perceptible to the refined ear of a Roman critic, though we can no longer discern it.

Livy's History was first printed at Rome, about the year 1469, by Sweynheym and Pannartz, in folio. Of this rare edition Lord Spencer is in possession of a fine copy; but the most exquisite one is that printed on vellum, which formerly belonged to the Imperial Library at Vienna, but was afterwards acquired by a private collector in England. Amongst the subsequent editions of the history may be mentioned that of Gronovius, "cum notis variorum et suis," Leyden, 1679, in three vols. 8vo; that of Leclerc, Amsterdam, 1709, in ten vols. 12mo; that of Crevier, Paris, 1735, in six vols. 4to; that of Drakenborch, Amsterdam, 1738, in seven vols. 4to, reprinted at Stuttgardt, 1820–1827, in fifteen vols. 8vo; that of Ruddiman, Edinburgh, 1751, in four vols. 12mo; that of Homer, London, 1794, in eight vols. 8vo; that of Oxford, 1800, in six vols. 8vo; and that of Ruperti, Göttingen, 1807, in six vols. 8vo. The edition of the first five books of Livy, by Dr John Hunter of St Andrews, Cupar Fife, 1822, is remarkable for its great accuracy, and is accompanied with English notes, in which are treated some of the most refined principles of philology. (See Lachmann, F. *De Fontibus Historiarum Livii, Comment.* 4to, Götting. 1822–1828. Maierotto, J. H. L. *De Candore Livii,* fol. Berlin, 1796; *De Testimoniorum Livii fide,* 1797; *De Livii Arte Narrandi et Artificio Historico,* 1798.)

LIVIUS ANDRONICUS, a comic poet who flourished at Rome about 240 years before the Christian era. He was the first who turned the personal satires and Fescennine verses, so long the admiration of the Romans, into the form of a proper dialogue and regular play. Though the character of a player, so valued and applauded in Greece, was reckoned vile and despicable amongst the Romans, Andronicus acted a part in his dramatical compositions, and engaged the attention of his audience by repeating what he had worked up after the manner of the Greeks. Andronicus was the freedman of M. Livius Salinator, whose children he educated. His poetry had grown obsolete in the age of Cicero, whose nicety and judgment would not even recommend the reading of it.

LIVONIA, a province or stadtholderate in European Russia. A part of Esthonia is now included in it, viz. Dorpat and the island of Oesel. It extends over 20,636 square miles, between 56. 34. and 59. 3. north latitude, and 23. 29. and 27. 32. east longitude. Though a great part of the province is sandy, and contains much woody, swampy, and heathy land, yet there are many portions of good soil, very productive in corn, hemp, and flax, which form the principal exports from Riga, and the several small ports along the shore of the Baltic. The inhabitants are about 800,000, the greater part of whom are of German origin, amongst whom the ancient tribes, the Letts and the Esthonians, are much mingled, though their original language has nearly disappeared. About two thirds of the population adhere to the Lutheran religion; the rest are Greeks, Catholics, or Jews. The trade is extensive in the export of native products; and in some seasons the quantity of corn grown beyond that consumed causes a brisk trade in grain, as well as in the spirits distilled from it, and pays for the salt, iron, lead, wine, and articles of luxury which the country does not yield.

LIVONICA TERRA, a kind of fine bole used in the shops of Germany and Italy. It is found in Livonia, from which it derives its name. It is in the form of little cakes.

LIVORNO, a town of the province of Vercelli, in Piedmont, containing 3640 inhabitants, who subsist by cultivating rice and breeding silk worms.

LIVRE, a French money of account, containing twenty sols or sous. See MONEY.

LIWNY, a circle of the Russian province of Orel, which extends in north latitude from 52. 49. to 53. 30. and in east longitude from 37. 16. to 38. 20. The capital is a city of the same name, situated on the river Sosna, 720 miles from Petersburg. It contains ten churches, 750 houses, and 6800 inhabitants. It is in latitude 53. 10. N. and longitude 37. 45. E.

LIXIVIOUS, an appellation given to salts obtained from burned vegetables by pouring water on their ashes.

LIXIVIUM, in *Pharmacy*, a ley obtained by pouring some liquor upon the ashes of plants. It is more or less powerful in proportion as it has imbibed the fixed salts contained in the ashes.

LIZARD, in *Geography*, a cape or promontory of Cornwall, situated, according to the most common computation, in long. 5. 47. W. and lat. 49. 50. N.

LJUBIM, a circle of the province of Jaroslaw, in Russia, extending between 57. 49. and 59. 2. north latitude, and 40. 10. and 40. 43. east longitude. It comprehends one city and 620 villages, which are divided into thirty parishes, each having a church. The inhabitants are 57,584. It depends wholly on agriculture and the breeding of cattle. The capital, of the same name, is situated on the river Obnora, 620 miles from St Petersburg. It contains four churches, 531 houses, and 1590 inhabitants. Long. 41. 1. E. Lat. 58. 6. N.

LLANBADARN VAWR, a market-town of Wales, in the county of Cardigan and hundred of Isar, 204 miles from London, and situated on the river Rydal. It is said to have been once a large city, the see of a bishop, and called Mauritania. Near to it, on the road to Aberystwith, are the remains of an extensive pile of buildings, which, according to tradition, was the castle of Owen Glendower. It is a corporate town, with a market, which is held on Tuesday. The population amounted in 1801 to 1228, in 1811 to 1373, in 1821 to 1479, and in 1831 to 1634.

LLANBEBLICK, a large parish of Wales, in the county of Carnarvon and hundred of Irwigfai, 250 miles from London. The town of Carnarvon forms part of this parish, and the population of the whole amounted in 1801 to 3626, in 1811 to 4595, in 1821 to 5788, and in 1831 to 7642.

LLANBEDER, or LLAMPETER, a market-town of Wales, in the county of Cardigan and hundred of Modwyn, 204 miles from London. It is situated on a fertile vale on the river Teife, over which a bridge, built by the king of that name, gives the town the addition of Pont Stephen. It is an ancient borough, having, with Cardigan, Aberystwith, and Aspar, formerly returned a member to parliament, and by the recent law it enjoys the same privilege. There is a market on Tuesday, and five fairs are held in the course of the year. The population amounted in 1801 to 1037, in 1811 to 750, in 1821 to 937, and in 1831 to 1317.

LLANDAFF, a small city, but so classed because it is the see of a bishop. It is in the hundred of Kibbon, of the county of Glamorgan, Wales, 162 miles from London, and is situated on the river Taff. The cathedral is an ancient building, of the architecture of various ages, and of most discordant styles, but containing some admirable monuments. The palace of the bishop may be traced by remains of ancient walls, and the building itself is reported to have been destroyed by the Welsh prince, Owen Glendower. Llandaff, though a city, has no market. It has a small harbour on the north bank of the Severn, two miles from Cardiff. The population amounted in 1801 to 860, in 1811 to 960, in 1821 to 1138, and in 1831 to 1299.

LLANDILLO VAWR, a market-town of South Wales, in the county of Carmarthen and hundred of Perfydd, 202 miles from London, situated on the river Towy, which abounds in fish, especially salmon. It has a well-supplied market on Saturday. The population of the town amounted in 1801 to 647, in 1811 to 776, in 1821 to 1019, and in 1831 to 1268; but the whole parish at the last census contained 5149 inhabitants.

LLANDOVERY, a market-town of South Wales, in the county of Carmarthen and hundred of Derlis. It stands on the river Towy, 188 miles from London. Near to it are the remains of an ancient castle, now covered with ivy. It has a market on Friday, and several fairs. It is not a parish, but forms part of the parish of Landingal. The population amounted in 1801 to 1395, in 1811 to 1442, in 1821 to 1820, and in 1831 to 2242.

LLANELLY, a town which had formerly a market, in South Wales, in the hundred of Carnwallen and county of Carmarthen. It is 220 miles from London. It stands on a creek running out of the Severn, called the Bury, at the mouth of which is an island, on which formerly stood the monastery of Machunis. The chief trade consists in the shipment of coals for Bristol, and the several towns of the north of Somerset and Devon. This commerce has increased the population, which, including the whole parish, amounted in 1801 to 2972, in 1811 to 3891, in 1821 to 5649, and in 1831 to 7646.

LLANGADDOCK, a town of South Wales, in the county of Carmarthen and hundred of Perfydd, 184 miles from London. It stands between the rivers Branc and Swathy. It has some manufactures of woollen stockings and coarse cloth. It contains three hamlets. There is an ancient castle, now in ruins. The market is held on Thursday. The population of the parish amounted in 1801 to 1821, in 1811 to 1964, in 1821 to 2484, and in 1831 to 2476.

LLANGOLLEN, a town of Wales, in the county of Denbigh and hundred of Chirck, 192 miles from London. It is in a most romantic situation on the river Dee, and on the great post road from London to Dublin. The bridge is an object of great curiosity. About two miles from it are the striking remains of Valle Cruces Abbey, and not far from it those of one of Owen Glendower's castles. It has a market, which is held on Saturday. The population of the whole parish amounted in 1801 to 2658, in 1811 to 2897, in 1821 to 3535, and in 1831 to 4498.

LLANOS, SAN JUAN DE LOS, a province in that part of the republic of Colombia which formerly constituted the viceroyalty of New Granada, being bounded on the north by Meridas and Varinas, on the east by Varinas, on the south by Quixos, and on the west by Bogota. Its limits are somewhat vague, the name signifying province of the plains, which extend their dreary surfaces from 200 to 300 leagues in length, and about the same in breadth. It is watered by many large rivers, the principal being the Rio Meta, the Casanare, the Vichada, and the Orinoco. The soil is fertile, and perfectly level: not a hill nor any other inequality is to be seen as far as the eye can reach. But the appearance of the plains is totally changed at different seasons of the year. During the rainy season they are covered with fine grass, on which numerous herds of cattle graze; and in the time of extreme drought, vegetation being destroyed by the excessive heat of the sun, they appear but a sandy desert. Upon the banks of the rivers, however, vegetation is at all times so profuse and often so thick as to be almost impenetrable. The climate is immoderately hot, and very unhealthy. In some parts the air is pure, and in others vaporous, and full of fine dust raised from the dried mud of the rivers.

The northern portion of this province has been recently separated into a distinct district called Casanare, which name is now often applied to the whole. In this territory, cacao, maize, yucas, plantains, &c. are produced; and the lakes and rivers furnish abundance of fish for the support of the inhabitants. Its principal town is Pore, situated in an unhealthy climate, about 133 miles north-east of Bogota, and containing 500 inhabitants. On the banks of the rivers there are many missionary and other villages, instituted for the conversion of the scattered tribes of Indians who roam through the country between the Orinoco and the Andes. These tribes are termed *Llaneros*, or inhabitants of the plains, whose chief employment consists in attending to the herds of cattle which feed on the pastures. The principal commodity of the plains is the peltry of animals manufactured by the inhabitants. The population, including Casanare, is about 20,000.

Llanos, *San Juan de los*, the capital of the above province, is situated in longitude 73. 55. 30. west, and latitude 3. 11. north, about fifty miles east-south-east of Bogota. It was founded in 1555, and was celebrated for the gold found in its neighbourhood, but now contains very few inhabitants, who live in great poverty.

LLAN-RHAIDAR-YN-MOCHNANT, a large parish of Wales, in the county of Denbigh and hundred of Chirck. It is situated in a deep hollow, and surrounded on every side by lofty mountains. It is much frequented by visitors, who go to it to get a view of the celebrated water-fall of Pistell-Raiadr. It is 224 miles from London. The population amounted in 1801 to 1869, in 1811 to 1974, in 1821 to 2229, and in 1831 to 2344.

LLANTRISSANT, a borough and market town of South Wales, in the county of Glamorgan and hundred of Miskin, 170 miles from London. In the neighbourhood are valuable lead mines. It has a market, which is held on Friday. In conjunction with Cardiff and Cowbridge, it will in future elect one member to parliament. The population amounted in 1801 to 1715, in 1811 to 2122, in 1821 to 2585, and in 1831 to 2789.

LLANVILLING, a borough and market town of North Wales, in the hundred of Llanfyling and county of Montgomery, 186 miles from London. It is well built, and was incorporated by Edward I. There is a good market on Tuesday. This town, in conjunction with Llanydloes, Welch-Pool, Machynlleth, and Newton, returns, under the new law, one member to the House of Commons. The population amounted in 1801 to 1394, in 1811 to 1508, in 1821 to 1706, and in 1831 to 1836.

LLANYDLOES, a market-town of North Wales, in the county of Montgomery and hundred of its own name, 190 miles from London. It is pleasantly situated on the right bank of the Severn. Plinlimmon, the highest mountain in Wales, is distant from it about seven miles. It joins with Welch-Pool, Machynlleth, Llanvilling, and Newton, in electing one member to the House of Commons. The population amounted in 1801 to 2282, in 1811 to 2386, in 1821 to 3145, and in 1831 to 4189.

LLOYD, William, a learned English writer and bishop, was born in Berkshire, in England, in 1627. He was educated under his father, rector of Sonning, and vicar of Tyle-hurst in Berkshire. He then went to Oxford, and finally took orders. In 1660 he was made prebendary of Rippon, and in 1666 chaplain to the king. In 1667 he took the degree of doctor of divinity; in 1672 he was installed as dean of Bangor; and in 1680 he was consecrated bishop of St Asaph. He was one of the six bishops who, with Archbishop Sancroft, were committed prisoners to the Tower of London, for subscribing a petition to the king against distributing and publishing his declaration for liberty of conscience. Soon after the Revolution he was made almoner to King William and Queen Mary. In 1692 he was translated to the bishopric of Litchfield and Coventry, and in 1699 to the see of Worcester, where he remained till his death, which happened in 1717, in the ninety-first year of his age. Dr Burnet gives him an exalted character, and his works are highly esteemed.

LOAD, or Lode, in *Mining*, a word used especially in the tin mines, and signifying any regular vein or course, whether metallic or not; but load most commonly means a metallic vein. When the substances forming these loads are reducible to metal, the loads are by the English miners said to be alive; otherwise they are termed dead loads.

Load is also used for nine dishes of ore, each dish being about half a hundredweight.

LOADSTONE. See Magnet.

LOAMS are defined to be earths composed of dissimilar particles, stiff, dense, hard, and rough to the touch; not easily broken whilst moist, readily diffusible in water, and composed of sand and a tough viscid clay. Of these loams some are whitish, and others brown and yellow.

LOAN, any thing given to another, on condition of return or payment.

Public Loans. See Funding System.

LOANDO, St Paul de, a city on the coast of Angola, capital of the Portuguese settlements in Western Africa. It is built partly upon a hill, which commands the surrounding country, and partly on the sea-shore, and covers a large extent of ground. It has no walls, but possesses a good fort, garrisoned by malefactors. The streets are wide and regular. The houses of the whites are built of stone, and those of the natives of mud and straw. The port is safe and spacious, and is defended from storms by an island lying in front. The city is the seat of a bishop, and possesses numerous churches and convents. The surrounding country is pleasant and fertile, abounding in cattle, corn, and fruits; but water is very scarce, and must be brought some distance. The climate during summer is warm, but regular sea-breezes moderate the heat considerably. The population is estimated at 3000 whites and free people of colour, without determining the number of slaves, one proprietor often having more than 100 in his service. Long. 13. 22. E. Lat. 8. 55. S.

Loando is also the name of an island situated opposite the city, and about twenty miles long and one broad. It is separated from the main coast only by a narrow channel. It produces no grain, but yields good pasture for sheep and goats, and there are some fisheries upon its coast. The wealthier inhabitants of the city have a number of country houses and gardens here for the purposes of recreation; and it also contains several small villages. It yields, by digging to a small depth, the best water in this part of the country, from which the city is principally supplied.

LOANGO, a considerable country in that part of the coast of Africa known by the name of Lower or Southern Guinea. Its limits are not accurately known. The country tributary to the king of Loango, however, extends from Cape Lopez to the river Congo, a distance of upwards of 400 miles; but Loango proper occupies only the middle part, being bounded by the town of Malemba on the south, and that of Mayomba on the north. The coast in some parts is high, of a red-coloured soil, and the hills are covered with a luxuriant vegetation; but generally it is composed of a very fine sand carried about by the slightest breeze. Towards the interior the soil is fertile, but little improved by an indolent people. The principal grains cultivated are, the manioc, which is used instead of bread, the maize, a species of pulse, and the potato, which grows to a much larger size and is of a stronger flavour here than in Europe. The palm and several other fruit-trees grow wild in abundance, and a great part of the country is covered with thick grass, which often attains the height of eight or ten feet. Wild animals are found, but generally of the smaller tribes; the Chinese hog, sheep, and goat, are used for domestic purposes. The climate is in general good. The year is divided into the dry and the rainy seasons, both of nearly equal duration. During the dry season, from April to October, the climate is exceedingly warm, and so entirely free from hurricanes or high winds, that vessels may anchor on any part of the coast with perfect safety. The temperature, however, is cooled by regular light breezes from the south and south-east. Rain occurs very seldom, and is never violent; but heavy dews fall during the night, which are sufficient for the support of vegetable life. In the rainy season the heat of the sun is greater than in the dry, and would be insupportable but for the great rains which fall and refresh the atmosphere. Iron and copper are found in the country, but the natives are not aware of the method of extracting them from the soil. Salt abounds in shallows along the coast, and is also obtained in the interior by boiling and allowing the water to evaporate. Trades and manufactures are entirely neglected, or only exercised as far as is absolutely necessary for the purposes of life. The inhabitants live in a state of great ignorance and superstition, and although several missions have been sent to the country, little or no good has come of them. The males are very indolent; their chief occupation is hunting or fishing; agricultural affairs they deem degrading, and leave to the females to perform. Their houses are built of straw and junk, and roofed with palm leaves bound together with small branches, which forms a covering impenetrable to rain. They are congregated in villages, and surrounded with palm and cocoa-nut trees, which are carefully kept from injury. The government is despotic, and the dignity is transmitted only in the female line. The princess has the right of choosing her husband, who is compelled to accept the honour, and is debarred the privilege of polygamy, enjoyed in an unlimited manner by his subjects. The king is elected by a council of seven, and it is necessary that the choice should fall on a prince of the blood. His authority is constitutionally absolute, but he is obliged to be circumspect in the use of it in the case of chiefs or tributary princes, who are often equal in power with himself. He is assisted in the executive government by several ministers of state, and great part of the judicial authority is exercised by an assembly in the different villages and towns. He is restricted from using any article not the produce of the country. The slave-trade was formerly carried on to a great extent in this country, but is now much diminished. The port of Loango was almost the exclusive theatre of this trade, but other towns on the coast are now equally frequented. From this practice the population is greatly diminished, and now scarcely exceeds 600,000.

LOANGO, a city, capital of the above kingdom, situated about a league from the sea, in a large and fertile plain. It is about four miles in circuit; but this extent is owing principally to the houses being built in squares, with large spaces between. The streets are long, straight, and kept very clean. The harbour is not deep enough to admit vessels of large tonnage, and its entrance is obstructed by a range of rocks stretching half way across. The coast around the city is recognised by red cliffs, which appear very brilliant when illuminated by the morning rays of the sun. There is some trade here in fine stuffs, manufactured by the inhabitants from leaves. The population is about 15,000. Long. 12. 13. E. Lat. 4. 40. N.

LOBBY, in *Architecture*, is a small hall or waiting-room. It is also an entrance into a principal apartment, where there is a considerable space between that and a portico or vestibule, and the length or dimensions do not allow it to be considered as a vestibule or an anti-room.

LOBE, in *Anatomy*, any fleshy protuberant parts, as the lobes of the lungs, the lobes of the ears, &c.

LOBESTEIN, a city, the capital of the principality of that name, in the dominions of the prince of Reus, of the younger branch. The principality extends over about 100 square miles, and contains 7500 inhabitants. The city is on an elevated stony spot, 1400 feet above the level of the sea, at the foot of which runs the river Lemnitz. It is surrounded with walls, and contains a residence of the prince, 417 houses, with 2960 inhabitants, who carry on some manufactures of linens and woollens. Long. 11. 42. E. Lat. 50. 26. N.

LOBO, JEROME, a Jesuit missionary, was born at Lisbon in the year 1593. He became a member of the society of Jesus at the age of sixteen, and in 1622 went out as a missionary to the East Indies. After making some stay at Goa, he sailed to the coast of Mozambique; and subsequently penetrated into Abyssinia, where his zeal and resolution drew upon him the hatred of the monks, in consequence of which he incurred much danger and suffering. On his return to Portugal he was shipwrecked on the coast of Natal, where seven months were spent in constructing shallops to bring away the survivors. One of these foundered, but that in which Father Lobo sailed arrived safe at Angola. After a variety of adventures he arrived at Lisbon; and he employed himself in the cause of the Ethiopian mission both at Madrid and Rome. He made a second voyage to the Indies, where he was appointed rector of the house at Goa. But he returned to Lisbon in 1658, and was chosen rector of the college of Coimbra, where he died in 1678, at the age of eighty-four. Lobo wrote an historical account of Abyssinia in the Portuguese language, which contains information both curious and valuable. It was translated into French by the Abbé Legrand, in 1728, in 4to; and the earliest production of Dr Samuel Johnson was an abridged version of this work into English.

LOCARNO, a market-town of the canton of Ticino, in Switzerland, alternately with Bellenz and Lugano, the capital thereof, as well as of the circle of its own name. It stands on the river Maggia, which, about one mile from it, falls into Lake Maggiore, or, as it was sometimes called, Lake Locarno. It is a romantic spot, and contains 340 houses, with 1600 inhabitants. Bell-founding is one of the trades carried on at it. Long. 8. 35. E. Lat. 45. 39. N.

LOCCUM, a town of the province of Calenbourg, in the kingdom of Hanover. It contains 152 houses, and 1120 inhabitants. It is remarkable for its abbey, which is possessed by a Protestant superintendent, and is the richest preferment of the church of Hanover, as the abbot of Loccum is the chief magistrate of the district, and has a seat in the upper legislative house of the states.

LOCHABER, a district of Inverness-shire, in Scotland. It is bounded by Moidart on the west, Glengary on the north, Badenoch on the east, and Lorn on the south. It derives its name from the lake or loch of Aber; and extends about twenty miles from east to west, and thirty from north to south. The country is barren, bleak, mountainous, and rugged. See INVERNESS-SHIRE.

LOCHES, an arrondissement of the department of the Indre and Loire, in France. It extends over 768 square miles, is divided into six cantons and seventy-six communes, and contains 58,500 inhabitants. The chief place is the city of the same name, in a fine situation on the left bank of the Indre, over which is a fine bridge. It is surrounded with vineyards, and is overlooked by an ancient castle, in the church of which is a monument in memory of the celebrated Agnes Sorel. It contains 640 houses, and 4800 inhabitants, who make some thin woollen goods. Long. 0. 54. E. Lat. 47. 7. N.

LOCK. This very useful article needs little description; but an explanation of the principles on which its security depends will probably be new and interesting.

The most essential portion of a lock is a bolt which can be thrown out or withdrawn only by its proper key; and the best lock is that which most perfectly prevents any other instrument from effecting this purpose.

There are two distinct modes by which this excellence has been sought; and a clear understanding of their principles and differences will greatly promote a due appreciation of the many ingenious contrivances to which the pursuit of this object has given rise.

The first mode consists in the insertion of fixed obstacles, called *wards*, to the entrance of other instruments than the proper key. They are placed between the keyhole and the bolt; and in good locks they are made numerous and intricate, for the double purpose of preventing access to the bolt, and of varying the patterns of the keys.

The second mode consists in the insertion of obstacles to the motion of the bolt; not fixed, therefore, like the *wards*, but moveable, by means of the proper key, into positions which give freedom to the bolt. They are frequently called *tumblers;* and we shall here apply that very expressive term to all moveable impediments to the retraction of the bolt, retaining the equally appropriate designation of *wards* to describe the fixed impediments to the introduction of surreptitious instruments.

These two means of protection, namely, wards and tumblers, may be applied separately or combined.

Till the middle of the last century, the locks used in Europe depended principally on the number and intricacy of their wards. But very little skill was exhibited even in this respect, though a great deal of misplaced labour and ingenuity was sometimes expended in fanciful decorations.

One very serious objection to the use of wards alone is, that they do not require to have exact counterparts in the key. It is true that the proper key is usually cut in perfect correspondence with the wards in the lock, but such accuracy is not indispensable, as the diagram figures 1 and 2 in Plate CCCXXIV. will render evident.

Let figure 1 represent the *bit* or *wet* of a key curiously cut. The essential parts of such a key are the pipe *a*, which fits on to the pin of the lock, and the extremity *bc*, which acts against the bolt. The intermediate portions are required merely to connect these two; the greater portion of the metal is therefore superfluous, and might clearly be removed, as shown in figure 2, which retains all that is wanted for connection and strength. But this facility of fabrication from an impression of the key is not the only evil. There is the chance that out of many variously formed skeletons, one will be found to pass almost any lock guarded by wards alone; to which may be added, the fact that an impression of almost any fixed wards may be obtained by introducing into the lock a blank key of proper size, having its bit covered with wax or tallow.

Whilst we are on the subject of keys, it may be noticed that some, instead of the small piercings, such as are shown in figures 1 and 3, have considerable portions of the bit cut away, more nearly resembling figure 2. In the former cases the wards are formed of thin iron plate; in the latter, of solid brass, and hence such locks are called solid warded. This peculiarity, however, adds nothing to the difficulty of picking, or of making false keys. The best sort of wards are those which intertwine from opposite sides of the bit, as in figure 3, which, it is obvious, would require to be more nearly imitated than the more numerous cuttings of figure 1. The bits of keys, as viewed end-ways, are variously shaped; the ordinary form is figure 4; figure 5 is called a taper bit, and figure 6 an S-shaped bit. No effect besides variety of pattern is obtained from these devices.

In reference to the operation called picking, the number and variety of the wards afford no security whatever. There must always be a clear passage in the lock for the revolution of the portion *bc* of the key, and through this passage the pick-lock introduces his *pick*, which is made semicircular for the purpose of passing round the exterior circle of the wards.

Locks destitute of tumblers may be generally recognized by a smart snapping noise in the act of locking, which arises from the pressure of a spring formed in the back of the bolt, and from which they are called back-spring locks. Figure 7 shows one of these locks, in which *a*, *a* are two notches on the underside of the bolt, connected by a curved part; *b* is the back-spring, which is here compressed by the passage of the curve through a limited aperture in the rim *cc* of the lock. The bolt is in the state called half-shot; when it is wholly shot, or wholly withdrawn, the notches *a*, *a* rest upon the rim *cc*, and the force with which they fall into this position, urged by the spring *b*, gives rise to the noise before mentioned. The back-spring lock is further objectionable from the facility with which the bolt may be forced back by any pressure applied to its end; an application which, on wooden doors and furniture, it is frequently possible to make.

The first improvement on the lock guarded by wards consisted in the addition of a single tumbler, as seen in figure 8. The bolt is here also supposed to be half shot, and it has two notches on its upper edge, which receive the stud *a* of the tumbler respectively, when the bolt is at one or other end of its course. The tumbler turns on a pin at its other extremity; it is forced downwards by a spring, and it is wide enough, lying behind the bolt, as shown by the dotted lines, to be elevated by the bit of the key.

This construction, in addition to a more or less perfect box of wards, forms what is called the common-tumbler lock, and which, though better than the back-spring lock, is easily picked, for this reason, that the tumbler merely requires to be lifted sufficiently high; if it be raised more than is necessary, the bolt is equally set free. An expert smith therefore finds little difficulty in throwing out the tumbler, and at the same time moving the bolt.

In this state the art of lock-making remained, when, in the year 1778, Mr Barron obtained his patent for what may be called the first scientific attempt to improve this very important instrument. Mr Barron increased the number of tumblers to two or more, and he so applied them, that mere elevation was no longer sufficient to release the bolt; they required a precise degree of elevation, neither more nor less, and each tumbler a peculiar quantity. Figure 9 will explain this ingenious and effectual change; the tumblers are shown by dotted lines behind the bolt, which latter has in its middle a groove or slit, notched on both edges, through which are seen projecting the studs of the tumblers. The bolt, as in the former cases, is supposed to be half shot; but it will be easily perceived, that if the studs of the tumblers rested in the lower notches, they would require to be elevated to the level of the groove before the bolt could be moved; and it is equally clear, that if lifted too high, they would be engaged in the upper notches, and would equally detain the bolt. The tumblers were made unequally wide, and demanded therefore similar inequalities in the bit of the key, which was stepped or notched, as shown in figure 3. The relative positions of the bolt and tumblers are seen in the section of the lock, figure 10. It must, however, be understood, that this and the former figures are not portraits of locks, but rather diagrams, to explain the theory of their action.

Barron's lock, when well made, with two or three tumblers, and a good box of wards, is extremely difficult, if not impossible, to pick; for the wards, which are useless as preventives to the operation of throwing up a single tumbler, greatly impede so delicate a proceeding as the elevation of two or more to a precise height; and this required delicacy of manipulation has formed the basis of all the subsequent attempts at improvement.

The first of these in time and ingenuity is that of Mr Bramah, who procured his patent in 1784, but afterwards very materially modified his invention. Mr Bramah's lock, though presenting little that is novel in principle, is singularly ingenious and compact in its arrangement; and it has the advantage of being chiefly formed in the lathe, by which means the most perfect accuracy of form is made compatible with very moderate cost.

Mr Bramah rejected entirely the use of fixed wards, employing only moveable guards, which we shall call tumblers, because they are analogous to the parts so named in Barron's and other locks. Of these he introduced never less than four, and frequently six or eight. Having no wards, he required no large bit on which to cut their counterparts; and thus he effected the double purpose of giving great portability to the key, and of so reducing the size of the key-hole as in some measure to compensate for the absence of wards as checks to any fraudulent attempts upon the tumblers.

The general features of this lock will be best understood from an examination of figures 11 to 16. It may be described as consisting of two brass barrels, the outer one, *aaaa*, being screwed to the plate or body of the lock, which is, however, not shown, and the inner one, *ccccc*, revolving within it. The inner barrel is shown detached in figures 14 and 15: it has a pin or stud *b*, which moves the bolt in the act of locking or unlocking, performing therefore the office of the bit of the ordinary key. The security of this lock depends, then, on certain contrivances, which prevent the revolution of this inner barrel, except on the application of its proper key. For this purpose, it has an external circular groove penetrating to the depth shown by the dotted circle in its section, figure 15; and it has four internal longitudinal grooves, as seen also in figure 15, but here seen occupied by what are in fact double pieces of steel-spring, formed like figure 16. These pieces of steel are the moveable guards or tumblers; and they prevent, except under certain circumstances, the revolution of the inner barrel. To do this, a thin plate of steel, called the locking-plate, *d d*, figures 11, 12, and 13, is screwed in two portions to the outer barrel, and at the same time occupies the external circular groove of the inner barrel, having four notches to receive the edges of the tumblers, figure 16, which lie in the internal longitudinal grooves. It will be seen now that the inner barrel is locked to the outer, because the tumblers of the inner barrel are detained in the notches of the locking-plate *d d*, which is screwed to the outer barrel. If, however, the tumblers be also notched as much as the locking-plate projects into their grooves, and if these notches be brought into the plane of the locking-plate, it is obvious that the barrel would then revolve, and the notches so formed would traverse the projection of the locking-plate into the longitudinal grooves. Such a notch is therefore formed in each tumbler; they are represented by the deepest of the three notches shown in the several figures, and are at various distances from the end of the tumbler. The smaller notches need not be alluded to at present. The tumblers have a projection at one end, by which they are pressed upwards by means of the spiral spring shown in figures 11 and 12. In the former figure, the tumblers occupy their usual position in the lock; in the latter they are unequally depressed by the unequal slits in the pipe of the key, so that their deep notches are now in the plane of the locking-plate, and the inner barrel is free to revolve. As the tumblers are unequally depressed, it is clear that only one of them (the lowest) can be supported by the spiral spring; the other three would therefore be left unsupported, but that they have sufficient friction in their grooves to retain them where they are placed, for the purposes of locking and unlocking. This friction is given by bending outwards the spring-plate of which they are made, as in figure 16; but it is not sufficient to prevent the spiral spring from elevating them all to the same level as soon as the key is withdrawn.

Such was Bramah's lock, as it first came extensively into use, and as it continued for many years, employed for the most important purposes, and by the most distinguished persons. At length an advertisement appeared in the public papers, requesting those who had lost keys of Bramah's locks, not, as had hitherto been done, to break open their doors or drawers, but to apply to the advertiser, who would undertake to save this destructive process by picking. And it appeared that an individual of great dexterity could perform this operation almost with certainty.

The effect of this discovery on the demand for the locks may easily be imagined; but the effect it had in stimulating ingenuity to provide a remedy, is one of the best illustrations of the proverb, that necessity is the mother of invention. Within a few days or weeks, Mr Russell, who was at that time employed in Mr Bramah's establishment, devised an alteration which at once, and without any expense, entirely overcame the difficulty, and converted the lock into one of perfect security. This contrivance is the most simple and extraordinary that ever effected so important an object; but before we describe it, we will endeavour to explain what has been called the *tentative* process of lock-picking, and which had been so successfully applied to Bramah's locks. To do this, we will refer to the diagram, figure 17, in which *a* represents a bolt fitting loosely an outer case, and tending to move in the direction of the arrow. It is, however, prevented by three studs, which are moveable upwards and downwards by their knobs, 1, 2, and 3; but it would be free to move if these studs were elevated or depressed to correspond with the notches made in the end of the bolt. Now, if the case were closed, it would be perfectly easy to place these studs in the requisite position by the following process: Apply a pressure to the bolt, which can be done in any lock, tending to move it for unlocking. This will of course be resisted by the studs 1, 2, 3, but not by all equally; it will in fact be resisted by only one of them; the necessary imperfections of all workmanship would prevent more than one at a time from coming into sensible contact with the bolt. Having therefore applied pressure to the bolt with one hand, with the other the operator would ascertain which of the studs was most bound by the pressure. This would be easily done, and then he would move the stud gently up and down till he felt it catch in the notch to which it belonged. The bolt would move till the next most prominent stud received it, which would be tracked to its notch in the same manner, and so on till all were disposed of.

By a similar process the picking of Bramah's lock was effected. A tendency to revolve was given with some force to the barrel; then, by means of a pair of small forceps, the several tumblers were tried, and it was ascertained which was most detained by the pressure against the locking-plate. That which offered most resistance was gradually depressed till its notch was felt to hang itself upon the locking-plate, and so on till the whole were depressed in succession, exactly as they would have been depressed simultaneously by the key.

Returning to figure 17, it will be easily understood, that if, in addition to the three principal notches, a number of shallower notches, as indicated by dots, be made, equal however in depth to any possible inequality in the projection of the studs, the process we have described is entirely prevented, because it will be perfectly impossible for the picker to tell whether he has brought the stud to one of the deep notches, or to one of the shallow or false notches; and he will of consequence be entirely baffled.

This was the happy suggestion to which we have alluded. This will explain the two shallow or false notches which now appear in the edges of Bramah's tumblers, and which require corresponding false notches, or rather false widening in the notches, of the locking-plate, as shown by the dots in figure 13.

From this time the art of lock-making presents nothing very decidedly new, though almost every year produces something which claims the public attention for a time, and is forgotten. From this description must, however, be excepted the lock of Mr Chubb, which has come into extensive use. It consists of Barron's tumblers, more or less numerous in proportion to the price, with few or no fixed wards, and without the false notches, or any similar contrivance. But it has an ingenious piece of mechanism called a *detector*, consisting of a lever, which, if any undue elevation be given to the tumblers, catches into and detains the bolt, till, by a peculiar application of the proper key, it is again released. Whether this detector be a more or less perfect guard than the others we have described, and whether it be or be not an advantage to learn that a false key has accidentally or designedly been introduced into a lock, are questions which remain open to discussion. Certain, however, it is, that by thus varying the construction of locks, we obtain the benefit of greater variety in the keys, which would otherwise be so multiplied of similar makes, as to neutralize in a great measure the benefits of the skill which has been applied to the locks. On this point it may be mentioned, that Bramah's keys, as made by himself and by Mordan, are constructed by a beautiful tool, which secures a constant change in the pattern, so that duplicates are not likely to recur for a long series of years.

Of the locks called "Combination Locks," it will not be required to say much. The common letter padlock is generally known; and, from the description here given of other locks, it will be easily understood that the lettered rings of the padlock are in fact tumblers, exposed to the operation of the hands, instead of being subjected to the concealed application of a key. These locks are not difficult to pick, though they might be made quite secure by the use of the false notches. There is indeed no tumbler lock to which this most invaluable idea might not be advantageously applied.

We have reserved till now the notice of a very curious lock, which is said to have been used for four thousand years in Egypt and Turkey, and which was first made well known to Western Europe through the French invasion of Egypt at the beginning of the present century, though it had been previously described by Eton in his Survey of the Turkish Empire. It appears to be extensively, or rather universally, employed for gates of towns and of houses, as well as for the smallest articles of furniture. The evidence of its alleged antiquity is derived, according to M. Denon (in whose magnificent work on Egypt it was published), from the circumstance of finding one sculptured amongst the bas-reliefs which decorate the great temple at Karnak, from which also it was ascertained that during forty centuries the lock had undergone no sensible change.

However this may be, its construction is singular and interesting, and particularly so because it makes exclusive use of *tumblers*, which, it will have been seen, were the last means of security adopted in this country. It will be understood by an examination of figures 18 to 21. In figures 18 and 19, *aa* is the case screwed to the door, and *bb* is the bolt. In the case, above the bolt, are a number of small cells containing headed pins, arranged in any form chosen by the maker. The top of the bolt has a number of holes similarly arranged, so that when brought into the right position, the ends of the headed pins may drop into the corresponding holes in the bolt. In this state the bolt is fastened. In order to unlock it, a large hollow or cavity is made at the exposed end of the bolt, which extends under the holes occupied by the pins. The key consists of a piece of wood, figs. 20 and 21, having pins arranged like those in the lock, and as long as the thickness of the bolt above the cavity. When therefore the key is introduced and pressed upwards, its pins exactly fill the holes in the bolt, and of course dislodge those which had fallen from the upper part of the case. The bolt may in consequence be withdrawn, as in fig. 19, leaving the headed pins elevated in their cells, instead of occupying the position shown by the dotted lines in fig. 18. It should be observed, that in fig. 19 the key is shown in its place, diminishing therefore the apparent size of the cavity in the bolt, which of course must be high enough to receive the key and its pins before the latter are lifted into the holes.

The attention excited by this lock when it was first made generally known caused its merits to be greatly overrated. M. Denon described it as no less secure than any other lock, and fit to be applied on all rural occasions. There would, however, be little difficulty in picking it, or in obtaining a wax impression of the holes; and there is an obvious awkwardness in the mode of using the key as compared with those revolving round fixed centres, which quite disqualifies it for superseding the modern lock. In other respects, it admits of considerable variety in the number, arrangement, and length of the pins; and by grooves in the top of the bolt they might be varied in the same lock. By a slight modification, also, it might have the benefit of Barron's invention, and require a precise degree of elevation. In fact, it has this principle to some extent; for if the pins be raised too much, whatever raises them will hold the bolt by entering into the upper cells.

Numberless contrivances for the improvement of locks, and some of great merit and ingenuity, will be found in the Repertory of Patent and other Inventions, in the Transactions of the Society of Arts, and in other scientific journals. Many of these will be found more curious than useful; such, for instance, as the locks which ring bells or discharge fire-arms when an attempt is improperly made to open them. Such, also, are the propositions to enlist magnetism into the service of lock-making, by employing polarized tumblers, and magnetic keys to act upon them, through the agency of magnetic attractions and repulsions, instead of the vulgar modes of pulling and pushing; and such are the locks made to open only by a peculiar sleight of hand, as if it were possible to preserve such tricks from the knowledge of those who are interested in acquiring them. A more useful class of inventions are the shifting or combination keys, whose parts may be kept by the owner in such a state of derangement as to require the knowledge of a certain cipher or motto in order to use them.

The theory of what have been called master keys, which figure more perhaps in romances than in the real world, will be understood by considering figures 1 and 2 of the engraving. It is clear that a great variety of locks might be made, with keys somewhat resembling figure 1; differing, however, sufficiently to be opened only by their respective keys, yet all of them adapted to the skeleton, or, in this case, the *master key*, figure 2. In this respect, the greatest facilities are presented by Bramah's arrangement. Any number of these locks, of the same size, and having the same quantity of tumblers, may be made to open by one key, though each be proof against any other of the series. For this purpose, nothing is required, but, after the completion of the locks, to cut in each an additional set of notches adapted to the intended master key, leaving the other notches to open it by the application of its peculiar key.

Lock ‖ Locke.

Locke.

Lock, or *Weir*, in inland navigations, the general name for all those works of wood or stone made to confine and raise the water of a river. The banks also which are made to divert the course of a river are called by these names in some places. But the term *lock* is more particularly appropriated to express a kind of canal enclosed between two gates; the upper called by workmen the sluice-gate, and the lower called the flood-gate. These serve in artificial navigations to confine the water, and render the passage of boats easy in passing up and down the stream. See Navigation, Inland.

LOCKE, John, one of the greatest philosophers that England has produced, was born at Wrington, Somersetshire, on the 29th of August 1632, ten years before Sir Isaac Newton. His father was a man of moderate estate, who had suffered by the civil wars, in which he served as a captain on the parliamentary side. After receiving his school education at Westminster, he was sent to Oxford in 1651, and soon became distinguished amongst his fellow-students of Christ Church for his learning, as well as his natural abilities. The philosophy of the schools then held entire dominion at Oxford; and, in after life, Mr Locke was heard to regret having consumed the most valuable time for study at that university, where, in those days, he could learn so little of what was really useful. But it is probable that much more has been made of these expressions than they deserve; for he must have derived considerable benefit from the leisure there afforded for cultivating privately other branches of learning, when he had perceived the futility of the scholastic system; and he undoubtedly enjoyed at that place advantages which led him thus early to form the idea of his great work. That he held self-education to be by far the most important of any, and had experienced this in his own case, there can be no doubt whatever.[1] The first productions that gave him a relish for the study of philosophy, were, it seems, the writings of Descartes, which, from their perspicuity and originality, no less than the boldness with which received opinions were impugned in them, naturally found favour with Locke, although he did not, in many cases, approve of the doctrines which they taught.

After having taken his degrees in arts, Mr Locke applied for some time to the study of physic, not so much, it is said, with a view to practice, as for the benefit of his own constitution, which was originally feeble, and required the observance on his part of a strict regimen. But he must have cultivated medical science to a far greater extent than this would seem to imply, because many of the learned in the faculty entertained a high opinion of his medical knowledge; and, in particular, Dr Sydenham, in his treatise on acute diseases, speaks of his great genius and sound judgment, in terms of very strong commendation. "You know," says he, "how much my method has been approved of by a person who has examined it to the bottom, and who is our common friend. I mean Mr John Locke, who, if we consider his penetrating genius and exact judgment, or the purity of his morals, has scarcely any superior and few equals now living."[2] Hence he was often saluted by his acquaintance with the title, though he never took the degree, of doctor, which he would probably have done had he intended to prosecute physic as a profession, or had he not been diverted from it by other studies and avocations.

In 1660, when the restoration had given rise to great controversies respecting the settlement of the church establishments, Locke appears to have written a tract on the subject, with the intention of printing it; but, from whatever cause, he abandoned his design. It has, however, been preserved, and is the earliest of his works extant. Lord King, in his Life of Locke, has given a few extracts from it, which are extremely interesting, inasmuch as they show how great a leaning he then had towards the side of authority, and how much he was disposed to recommend concessions, upon matters not absolutely essential, for the sake of avoiding civil anarchy and religious discord. The excesses of those who had been the real friends of liberty, but who chose to represent themselves as its only friends, appear to have alarmed him so much as to lead him to think somewhat too favourably of their antagonists. "Since I find," says he, "that a general freedom is but a general bondage; that the popular assertors of public liberty are the greatest engrossers of it too, and not unfitly called its keepers; I know not whether experience would not give us some reason to think, that were the part of freedom contended for and indulged in England, it would prove only a liberty for contention, censure, and persecution." He then states that liberty, in his view of it, is "not a liberty for ambitious men to pull down well-framed constitutions, that out of the ruins they may build themselves fortunes, nor a liberty to be Christians, so as not to be subjects; but that all he can wish for his country or himself is, to enjoy the protection of those laws which the prudence and providence of our ancestors established, and the happy return of his majesty has restored." Such are often the early impressions of those whom reflection and experience afterwards conduct to sounder conclusions. Nothing, in truth, can be more natural, than to feel disgust at the extravagance, intolerance, and injustice of the men with whom we are agreed upon points of essential importance. When we find them ready to persecute us the moment they detect the least difference in our sentiments, it is almost unavoidable to stigmatise them as "the engrossers and keepers of liberty." But the worst effect of such pretensions to infallibility, and of the excesses to which it leads, is, that it sometimes tempts honest and conscientious men to fall into the error of Locke, and to betray a disinclination towards the cause itself, because its most forward professors demean themselves in an overbearing manner. This feeling, be it observed, makes Locke here speak the language of the friends of the Restoration, and overlook those more lasting evils which have almost always attended the return of exiled sovereigns. A short time only elapsed, indeed, before he was made fully sensible of his oversight. The high-church party, finding themselves strong in the new parliament, abandoned all notion of comprehension; and, more intolerant than the Presbyterians themselves, they sought to make differences in all matters, however trivial, operate an absolute exclusion. This change prevented the publication of the tract above mentioned, by rendering its object unavailing.

---

[1] The following passages from two letters to Lord Peterborough set this in a strong light. In answer to a letter from his lordship, who had applied to him to recommend a tutor to his son, he says, "I must beg leave to own that I differ a little from your lordship in what you propose; your lordship would have a thorough scholar, and I think it not much matter whether he be any great scholar or no: if he but understand Latin well, and have a general scheme of the sciences, I think that enough; but I would have him well bred, well tempered; a man that, having been conversant with the world and amongst men, would have great application in observing the humour and genius of my lord your son, and omit nothing that might help to form his mind, and dispose him to virtue, knowledge, and industry. This I look upon as the great business of a tutor; this is putting life into his pupil, which, when he has got, masters of all kinds are easily to be had; for when a young gentleman has got a relish of knowledge, the love and credit of doing well spurs him on; he will, with or without teachers, make great advances in whatever he has a mind to. Mr Newton learned his mathematics only by himself; and another friend of mine Greek, wherein he is well skilled, without a master; though both these studies seem more to require the help of a tutor than almost any other." And, in a letter to the same person on the same subject, he says, "when a man has got an entrance into any of the sciences, it will be time then to depend on himself, and rely upon his own understanding, and exercise his own faculties, which is the only way to improvement and mastery." After recommending the study of history, he proceeds to observe, "The great end of such histories as Livy, is to give an account of the actions of men as embodied in society, and so of the true foundation of politics; but the flourishings and decays of commonwealths depending not barely on the present time for what is done within themselves, but commonly on remote and precedent constitution and events, and a train of concurrent actions amongst their neighbours as well as themselves; the order of time is absolutely necessary to a due knowledge and improvement of history, as the order of sentences in an author is necessary to be kept to make sense of what he says. With the reading of history, I think the study of morality should be joined; I mean not the ethics of the schools fitted to dispute, but such as Tully in his *Offices*, Puffendorf *de Officio Hominis et Civis*, *de Jure Naturali et Gentium*, and, above all, what the New Testament teaches, wherein a man may learn to live, which is the business of ethics, and not how to define and dispute about names of virtues and vices. True politics I look on as a part of moral philosophy, which is nothing but the art of conducting men right in society, and supporting a community amongst its neighbours."

[2] "Nosti præterea quam huic meæ methodo suffragantem habeam, qui eam intimius per omnia perspexerat utrique nostrum conjunctissimum dominum Joannem Locke; quo quidem viro, sive ingenio judicioque acri et subacto, sive etiam antiquis, hoc est, optimis moribus, vix superiorem quenquam, inter eos qui nunc sunt homines repertum iri confido, paucissimos certe pares." "The merit of this method, therefore," says Mr Stewart, in his Dissertation on the progress of Intellectual Philosophy, "which still continues to be regarded as a model by the most competent judges, may be presumed to have belonged in part to Mr Locke; a circumstance which deserves to be noticed, as an additional confirmation of what Bacon has so sagaciously taught concerning the dependence of all the sciences, relating to the phenomena either of matter or of mind, on principles and rules derived from the resources of a higher philosophy: on the other hand, no science could have been chosen more happily calculated than medicine to prepare such a mind as that of Locke for the prosecution of those speculations which have immortalized his name; the complicated and fugitive, and often equivocal, phenomena of disease, requiring in the observer a far greater portion of discriminating sagacity than those of physics strictly so called; resembling in this respect, much more nearly, the phenomena about which metaphysics, ethics, and politics, are conversant."

In 1665, Mr Locke accompanied Sir Walter Vane, as secretary, on his mission to the elector of Brandenburg; but he returned to England within the year, and went back to Oxford, where he resumed his studies with great vigour, and, in particular, applied himself to that of natural philosophy. He refused two offers of diplomatic employment, in Germany and Spain, which were made to him at different times; and he was also pressed by a friend, who had interest with the Duke of Ormond, then lord-lieutenant of Ireland, to take orders, and accept of considerable preferment in the Irish church. Mankind have reason to be thankful that this great man did not subside into a professional diplomatist; but there is no reason to conclude, as Lord King has done, that, had he accepted of preferment in the church, he would never have attained the name "of a great philosopher, who has extended the bounds of human knowledge." There appears, indeed, to be nothing in the peculiar duties of a divine which should incapacitate or disqualify him for engaging in scientific pursuits; and the annals, both of the English and of other churches, abound in examples of the successful cultivation of philosophy by their ministers. Berkeley was an Irish bishop; yet he unquestionably attained the name of a great philosopher, and, by his admirable Essay on Vision, extended the bounds of human knowledge.

In the year 1666, commenced Locke's acquaintance with Lord Ashley, afterwards Earl of Shaftesbury. His lordship had repaired to Oxford, with the intention of taking some mineral water for an abscess in the chest, under which he then laboured; and the physician to whom he applied, being absent, requested Locke to receive the distinguished visitor. Deeply versed in medical science, although he had not practised it professionally, Locke seems to have promptly divined the true mode of treatment for his lordship's complaint; whilst the charms of his conversation, in which wit, and sense, and learning were happily blended, could scarcely fail to make a deep impression upon a person of Shaftesbury's taste and discernment. Locke in his turn could not avoid being captivated by the brilliant qualities of a man whose genius and exemption from all vulgar corruption were sufficient to gloss over the most turbulent ambition, and the greatest sacrifice of principle and consistency which was ever, perhaps, made for its gratification. At the time when Locke made his acquaintance, he had, after serving the parliament in the civil wars, and being a zealous partisan of Cromwell during the protectorate, devoted himself to the cause of the restoration, and become a courtier of the sovereign from whom he derived his nobility. Mr Locke now accompanied Lord Ashley from Oxford to London; and having engaged him to submit to an operation which saved his life, such an intimacy grew up between them, that Locke was the inmate of Ashley House during a considerable part of every year, with the exception of three, which he spent abroad; and he was consulted by Shaftesbury upon all his most important private concerns. The part of his time which he did not spend with Lord Shaftesbury was passed at Oxford, where, as early as the year 1670, he appears to have sketched the plan of his Essay concerning Human Understanding. Lord King seems to think that this immortal work was completed in the following year; for he informs us that "the original copy, in Locke's own handwriting, dated 1671, is still preserved." But in this copy much must have been left to be added; for it was during his exile in Holland, as we learn from Leclerc, that Locke finished his Essay, and the year 1687 is mentioned as that in which it was completed. Besides, even after the work had been published, material and important additions were made to the subsequent editions, particularly the second and the fourth.

Towards the close of the year 1675, Locke went to reside in the south of France for the benefit of his health, and thus was happily absent during the disgraceful excesses connected with the pretended Popish Plot. Although his pure and tolerant principles must, with all right-thinking men, have exempted him from the least suspicion of encouraging Shaftesbury in the part which he then took, even if he had been residing with that unprincipled nobleman; yet it is fortunate for his fame, that the distance at which he then was from those dismal scenes deprives the most uncandid reasoner of every pretence for charging him with any participation in them. He kept a full and regular Journal of his travels from the day he landed at Calais; and one of the most curious and interesting portions of Lord King's work consists in the remarks upon men and things which he has extracted from it. Nor are any of these observations more instructive than those which convey to us an idea of the state of things which prevailed under the old government of France, the overthrow of which has been so bitterly lamented by a certain class of politicians in this country. Thus we find an estimate of the revenues of the Gallican church, according to which they amounted to not less than twenty-four millions sterling a year. The exemption of the lands of the nobility from taxes, as well as the ancient church lands, formed another glory of the old system, which the Revolution mercilessly swept away. The oppressive *gabelle*, or salt-duty, and the abuses of its farmers, as well as the laws for enforcing its collection, are also fully exposed. "The salt," says the Journal, "which the owner sells for five sous, the farmer sells again for fifteen;" and "the defrauding the duty is of such consequence, that if a man should be taken with but an handful of salt not bought from the farmers, he would be sent to the galleys." Nor was the corruption in the administration of justice less flagrant and odious than the iniquity of the financial system. "Many murders are committed here (at Montpelier). He that endeavoured to kill his sister in our house, had before killed a man, and it had cost his father five hundred crowns to get him off; by their secret distribution gaining the favour of their counsellors." Under such a system, the condition of the common people was, of course, most wretched. "Their ordinary food is rye-bread and water; flesh seldom seasons their pots; they can make no distinction between flesh and fasting days, but when their money reaches to a more costly meal, they buy the inwards of some beast in the market, and then feast themselves."

At Versailles, Mr Locke saw the other extreme of French society under the same happy dispensation. The queen sat on one hand of Louis XIV., and Madame de Montespan, his majesty's mistress, sat on the other, in the royal box at the opera. The latter also attended him in like manner at a hunting party. This monarch was, however, exceedingly punctual in his devotional exercises. "At the king's levee," says Mr Locke, "which I saw this morning, there is nothing so remarkable as his great devotion, which is very exemplary; for as soon as ever he is dressed, he goes to his bedside, where he kneels down to his prayers, several priests kneeling by him, in which posture he continues for a pretty while, not being disturbed by the noise and buzz of the rest of the chamber, which is full of people standing and talking to one another." Here we have a pretty conspicuous example of that blessed condition, "where prayers are morality, and kneeling is religion."

The same Journal contains some dissertations of very great value. The most complete and instructive of these is that upon Study. The sagacity and plain strong sense of Locke, and his freedom alike from the trammels of prejudice, or any affectation of originality, form the distinguishing features of this piece, as of all the illustrious author's works, and impress us with the persuasion, that if he differed from received opinion, it was simply for the love of truth, and not for the sake of appearing wiser than other men. In this discourse he lays it down that there are so many things to be known, whilst our time on earth is so short, that we must at once reject all useless learning. The first parcel of lumber which he condemns to be thrown over board, is all that maze of words and phrases invented to instruct people in the art of disputing, and abounding in the logic, physics, and divinity, of the schools. "Such words," he says, "no more improve the understanding than the motion of a jack will fill our bellies." Next he condemns a too great desire to know what opinions other men have entertained. He does not undervalue the light which we receive from others, nor think that there are not books which assist us mightily in our endeavours after knowledge; but he conceives that it is idle and useless to make it one's business to study what have been other men's sentiments in things where reason is, after all, the only judge. The third class of rejected studies consists of "purity of language, a polished style, or exact criticism in foreign tongues;" under which head, he says, are to be comprehended Greek and Latin, as well as French and Italian. To spend much time upon such niceties he considers as only labouring for an outside, a handsome dress of truth and falsehood, which may become fashionable gentlemen, but is unsuited to wise and useful men. But from this prohibition, which we cannot help thinking a great deal too broad, he specially excepts whatever amount of philological learning may be required for the right interpretation and understanding of the Scriptures; a case for which, according to his system, no sufficient provision is made, and which seems indeed to be excluded by the general prohibition. Another branch of proscribed study comprehends all "nice questions and remote useless speculations; as, where the earthly paradise was, what kind of bodies we shall have at the resurrection," and such like insoluble difficulties. The remarks upon useless historical study are judicious and discriminating; and the rest of the discourse is well worthy of attentive consideration, however much we may be disposed to dissent from some of the author's principles and views.

Amongst the lesser pieces which are inserted in the Journal under different dates, the most curious is one upon Religion, in which Tillotson's argument against the doctrine of the real presence, which is naturally turned by Hume into an argument against the possibility of miracles, is very clearly anticipated. He begins by affirming that the being and attributes of God can only be discovered and judged of by natural reason. Any other source of knowledge can only be inspiration; but even this, according to Mr Locke, cannot be admitted by any one who receives it, much less by any other to whom he tells it, as the ground of believing an alleged supernatural communication, excepting in as far as it is conformable to reason, which alone can enable either the one or the other to distinguish between inspiration and fancy, revelation and delusion. He holds it to be impossible that God should have made a creature to whom the knowledge of himself was necessary, and yet only imparted that knowledge by a channel through which all manner of errors are conveyed into the mind; "a channel much more likely to let in falsehoods than truths, since nobody can doubt, from the contradictions and strangeness of opinions concerning God and religion in this world, that men are likely to have more frenzies than inspirations." He next proceeds to inquire how far inspiration can enforce any opinion concerning God or his religion, when accompanied with a power to work miracles; and here again he maintains that "the last determination must be that of reason." His remarks upon religious enthusiasm are a continuation of the same argument; and although the definition of "enthusiasm" is not guarded by proper limitations, and consequently may admit of a dangerous extension, it ought at the same time to be kept in view that the sentiments of Locke upon this subject are those of a man who approved himself a sincere and devout advocate of the cause of Christianity. His observations concerning miracles bear date September 1681, and, consequently, must have been written a considerable time before Tillotson's discourse against transubstantiation, which appears to have been composed about the end of the reign of Charles II.[1]

Locke's return to England was accelerated by Shaftesbury, who had been taken into the ministry, and was now president of the council which the king had appointed, with the view of promoting conciliation. This measure, and the appointment of the popular leaders to office, was adopted by the advice of Sir William Temple; but the whole arrangement had not his concurrence, for he protested so vehemently against Lord Shaftesbury's admission, that it made him rather desire the whole plan should miscarry than be executed with such an addition.[1] It is also incorrect to represent Lord Shaftesbury's resignation as voluntary, and, like Lord Russell's, the consequence of the king proroguing the new parliament, chosen after he had dissolved the short one which succeeded the pensioned parliament, and passed the first exclusion bill and the *habeas corpus* act. Shaftesbury was deprived of his place as president of the council by the king, about the same time that he made the Duke of Monmouth retire to Holland, in consequence of the intrigues of Essex and Halifax, and the Duke of York's coming over, at their suggestion, on the occasion of the king's illness. This is the account given of the transaction by Temple; and Hume, though he makes Shaftesbury's removal take place at the date of the prorogation, yet is so far accurate that he does not describe him as resigning, but as dismissed. The account of this transaction given by Burnet is nearly the same with that of Temple.[2] Mr Locke arrived in England in May 1679, about a fortnight after the new council had been formed; and it may be presumed that he was living in his usual habits of familiar intercourse with Shaftesbury during that remarkable session when the exclusion and *habeas corpus* bills were powerfully supported by his lordship's talents and zeal. But the asthma, with which Mr Locke was afflicted, obliged him to pass the greater part of his time either at Oxford or in the west of England; notwithstanding which, several passages in his Journal plainly show his sense of the delirium which still prevailed upon the subject of the Popish Plot. The trials of the five Jesuits, and of Langhorne, the lawyer, were then going on, or in preparation; that of Sir George Wakeman, the queen's physician, took place in the month of July, when he was acquitted. This may be said to have terminated the frenzy, so disgraceful to the nation; for, excepting that of Strafford, Wakeman's was the last of the trials. Lord Shaftesbury was now in avowed opposition to the court; and for some time his party had every success that could be expected, short of passing the exclusion bill, in which they were always foiled by the House of Lords. The new parliament had been returned with a decisive majority in favour of the country party. The king dissolved it, and another of the very same description was chosen. This the king also dissolved suddenly in March 1681; and, within a month or two, the most humiliating spectacle which the history of popular fickleness presents, either in ancient or modern times, was exhibited by the people of England.

---

[1] It is not a little remarkable that, a few years before this, Locke accidentally came near to one of the greatest discoveries of physical science, that of fixed air, which, a century afterwards, changed the whole face of chemistry. "M. Teinard produced a large bottle of muscat; it was clear when he set it on the table, but when he had drawn out the stopper, a multitude of little bubbles arose, and swelled the wine above the mouth of the bottle. It comes from this, that the air which was included and disseminated in the liquor, had liberty to expand itself, and to become visible, and, being much lighter than the liquor, to mount with great quickness. Q. Whether this be air new generated, or whether the springy particles of air in the fruits out of which these fermenting liquors are drawn, have by the artifice of nature been pressed close together, and thereby other particles fastened and held so; and whether fermentation does not loose these bonds and give them liberty to expand themselves again? Take a bottle of fermenting liquor, and tie a bladder on the mouth. Q. How much *new air* will it produce? *Whether this has the quality of common air?*"

The whole tide of popularity now turned in favour of the court and the king, and even the Duke of York. The sanguinary delusions of the Popish Plot seem to have stricken the infatuated nation with a kind of compunctious self-hatred, which was to be gratified only by rushing blindly to the opposite extremity. From grand juries, the bench of justices in the counties, cities, and boroughs, the franchises and corporations, many manors, the companies in towns, and, lastly, from the very apprentices, addresses were sent up, the purport of which was to declare unlimited confidence in the king, readiness to devote lives and fortunes to his service, condemnation of the exclusion bill, and charges of a seditious and even treasonable nature against the late parliament for having faithfully represented the sense, or rather the violence, of those very parties on the subject of popery and the Duke of York. As for the clergy, they struck up even a higher note of servility, evincing as much zeal for the duke's succession "as if a Popish king had been a special blessing of heaven to be much longed by a Protestant church."[3] The court perceived its advantage, and improved it by turning out of the commissions of the peace and the militia all whose attachment was considered as doubtful. And then began that campaign of judicial murders, which continued without pity or remorse until the end of this reign, and which plainly showed, as indeed the whole history of despotism in this island proves, that, with scarcely any exception, the judges of the land have ever been found the ready instruments of the most cruel and profligate of our tyrants. Indeed almost the only person who escaped their servile violence was the least deserving of those whom the court had resolved to destroy. Lord Shaftesbury being charged with high treason, the grand jury threw out the bill; but this was the last instance of resistance to the pleasure of the court. All the other victims of its malignity were regularly handed over to the "justice" then administered by the despot's ermined sycophants, who, we are authorized by legislative authority to say, murdered them in detail. As it was manifestly dangerous for Shaftesbury to rely upon the frail chance of a second escape, he retired to Holland, where he soon afterwards died; and his illustrious friend, deeming it unsafe to remain any longer in a country thus ruled and judged, went also into voluntary exile, about the close of the year 1683.[4]

At this period Locke was removed from his studentship at Christ Church, by virtue of an illegal order of the king, cheerfully, nay, almost thankfully, submitted to by the time-serving priest who then held the see at Oxford and the deanery of Christ Church. The common version of this memorable passage in his life, which treats it as an expulsion, and as the act of the university, is incorrect; it was merely a deprivation of his collegiate situation by the dean and chapter of the lesser body. The correspondence between the court of St James's and their wretched slaves of the university is very remarkable. In November 1684 Sunderland writes to Bishop Fell that the king understands that "one Mr Locke, who belonged to the late Lord Shaftesbury, and has on several occasions behaved himself very factiously and undutifully to the government, is a student of Christ Church," and adds, "that his majesty would have him removed from being a student, and that in order thereto the bishop would let them know the method of doing it." The answer of the right reverend prelate is instinct with unparalleled meanness and treachery. After stating that he had "for divers years had an eye upon" Locke, in order, no doubt, to find matter of charge against him, but that ("so close had his guard been of himself") all this episcopal espionage proved unavailing; and "although very frequently, both in public and in private, discourses have been purposely introduced, to the disparagement of his master the Earl of Shaftesbury, his party and designs, he could never be provoked to take any notice, or discover in word or look the least concern," Bishop Fell proceeds thus: "He has here a physician's place, which frees him from the exercise of the college, and the obligation which others have to residence in it, and he is now abroad upon want of health; but *notwithstanding that,* I have summoned him to return home; which is done with this prospect, that, if he *comes not back,* he will be liable to *expulsion for contumacy;* if he *does,* he will be *answerable to your lordship for what he shall be found to have done amiss;* it being probable, that though he may have been thus cautious here, where he knew himself to be suspected, he has laid himself more open in London, where a general liberty of speaking was used, and where the execrable designs against his majesty and his government were managed and pursued. If he does not return by the first day of January next, which is the time limited to him, I shall be enabled of course to proceed against him to expulsion. But if this method seem not *effectual or speedy enough,* and his majesty shall please to command his *immediate remove,* upon the receipt thereof, by the dean and chapter, it shall accordingly be executed." This letter is dated the 8th of November 1684. The immediate answer of Sunderland brings the grossly illegal order of the crown to deprive; and the bishop forthwith replies that it has been "fully executed," which elicits an expression of satisfaction on the part of the king "with the college's ready obedience;" an expression with which that learned body was probably satisfied, until its members should have occasion for some more substantial mark of approbation. But this is not all. There is still extant a letter by Bishop Fell, dated the 1st of June 1680, about four years before this, and addressed to Mr Locke himself, which proves that this right reverend pander of despotism, and forward tool of persecution, was the friend of the man whom he now showed himself so eager to betray.

[1] Temple, *Memoirs from 1629 to his retirement.*

[2] Burnet, *History of his own Times*, vol. ii. p. 477.

[3] Burnet, *History of his own Times*, vol. ii. p. 501.

[4] That the mitre was not behind the ermine in the foul contamination of those times, abundant proof may be found, both in the general conduct of the church as described by Burnet, and in the strain composed by the heads of the hierarchy, to testify the gratitude of the nation for its enslavement. Lord King has given a form of prayer appointed for the thanksgiving holden upon the 9th of September 1683, which, he justly observes, "might have been supposed to proceed rather from the mufti and ulema, than from the bishops and rulers of the Christian church of England." They exult in the reflection that God "had given their gracious king, Charles, the necks of his enemies;" that is, of the virtuous Lord Russell, who had suffered, and of Sidney, who was yet to be delivered over to the inhuman Jefferies. They acknowledge that in all ages the Almighty has "shed forth his power in the miraculous protection of *righteous* and *religious* kings;" and "yield, from the very bottom of their hearts, *unfeigned* thanks" for the delivery of those two "righteous and religious" princes, Charles and James, from the "unnatural and hellish conspiracy of wicked and ungodly men." Upon these princes and their posterity they pray that the crown may forever flourish; and, under the form of a prayer for enemies, they pour out all imaginable abuse of their political antagonists, expressed in terms so gross that we shall not pollute the purity of this work by quoting them.

There can be but one opinion as to this prelate's base and treacherous conduct in the matter of Mr Locke's removal from his college; yet we must not shut our eyes to the lesson which is afforded by the proceeding of the court. It is a mistake to suppose that absolute princes are not so much to be abhorred as mean and petty tyrants, because they never come into conflict with individuals. Upon this subject, which he had long and profoundly considered, Mr Fox has, in his history, expressed a different opinion. "Thus," says he, "while, without the shadow of a crime, Mr Locke lost a situation attended with some emolument, and great convenience, was the university deprived of, or rather thus, from the base principles of servility, did she cast away, the man, the having produced whom is now her chiefest glory; and thus to those who are not determined to be blind, did the true nature of absolute power discover itself, against which the middling station is not more secure than the most exalted. Tyranny, when glutted with the blood of the great and the plunder of the rich, will condescend to hunt humbler game; and make the peaceable and innocent fellow of a college the object of its persecution. In this instance, one would almost imagine there was some instinctive sagacity in the government of that time, which pointed out to them, even before he had made himself known to the world, the man who was destined to be the most successful adversary of superstition and tyranny." It affords a striking confirmation of these remarks, that Charles, not satisfied with driving Locke from the situation which he held in England, and which in a great measure formed the means of his subsistence, followed him to the retreat abroad, where he had sought shelter from tyranny, and demanded, through his ambassador at the Hague, that the illustrious exile should be given up to his vengeance. Locke was therefore obliged to live in concealment during part of his residence in Holland; and it was about this time that he, appropriately enough, composed that admirable Letter on Toleration, which has ever since its publication been the chosen manual of the friends of religious liberty.

Mr Locke remained in exile until the Revolution, having refused many offers from powerful friends to obtain the king's permission to return. William Penn, amongst others, having some favour with James II., and probably fancying he had more, offered to procure him a pardon; but Locke nobly refused to accept one, being conscious of no offence.[1] Upon his return to England, he was pressed to accept a high diplomatic situation in Germany; but declined, partly from a modest apprehension of his insufficiency, and partly from an idea that his health would not stand the climate, and the service, of which he seems to have formed a somewhat unfavourable opinion. He states his reasons in a letter to Lord Mordaunt, afterwards Earl of Peterborough, in which he says, "I beg leave to tell your lordship, that if there be any thing wherein I may flatter myself I have any degree of capacity to serve his majesty, it is in some little knowledge I perhaps may have in the constitutions of my country, the temper of my countrymen, and the divisions amongst them; whereby I persuade myself I may be more useful to him at home, though I cannot but see that such an employment would be of greater advantage to myself abroad, would but my health consent to it."

His great work, the Essay concerning Human Understanding, was first published in the year 1690. The second edition appeared in 1694, the third in 1697, and the fourth in 1700.[2] The second edition received an additional chapter, namely, that on Identity; and the fourth, two more chapters, one on Association of Ideas, and another on Enthusiasm. Besides these entire chapters, various other partial additions and alterations were made by the author in the editions referred to. By this work Mr Locke soon became involved in several controversies. That with Stillingfleet, bishop of Worcester, is well known; and he also appears to have been teazed with another, which the third Lord Shaftesbury, the distinguished author of the Characteristics, insisted upon carrying on in private, by means of letters, which, though clever enough, are at the same time models of flippancy and affectation.

Soon afterwards, Locke took an active and most useful part in the great political discussions of the time. The toleration act, it is well known, was chiefly promoted by him, although he always lamented that it stopped so far short of the true point. His treatise on Civil Government, written in defence of the Revolution, against the Tories, and a second letter in defence of toleration, were both published in 1690. The act passed in 1662, establishing a censorship of the press, under pretence of preventing irreligious publications, remained in force, as is well known, until the year 1694, when it was allowed to expire, the House of Commons having refused to renew it. Upon that occasion Mr Locke probably prepared the curious and valuable piece which was first published by Lord King, and contains the author's observations upon the objectionable clauses of the bill. In considering these, it is interesting to observe that one of the substitutes for a licenser, which he points out, is the law passed above a century afterwards; whilst at the Revolution, when men's tempers were much heated, and their party differences ran as high as they ever did since, our ancestors were content to abolish the censorship, which had existed about thirty-two years, and to take no surety against the licentiousness of the press beyond that which had been provided by the common law. "I know not," says Mr Locke in the admirable piece referred to, "why a man should not have liberty to print whatever he would speak; and to be answerable for the one, just as he is for the other, if he transgresses the law in either."

---

[1] Much about the same time, Penn busied himself with Bishop Burnet, and tried to bring him also over to England. The bishop, however, seems to have had but very little confidence in him. "He was," says he, "a talking vain man; he had such an opinion of his own faculty of persuading, that he thought none could stand before it; but he was singular in that opinion, for he had a tedious, luscious way, that was not apt to overcome a man's reason, though it might tire his patience." (Burnet, *History of his own Times,* vol. i. p. 693.) He tried to persuade the Prince of Orange, and indeed undertook to bring him into the king's measures, but of course without the least success. He also told Bishop Burnet many prophecies which he said he had from "a man that pretended to a commerce with angels." Amongst other things, he foretold, in 1686, that a change in the face of affairs would happen in 1688, and amaze all the world. But when, after the Revolution, Burnet asked him if that was the event, he had the rare candour to admit that he meant "the full settlement of the nation, upon a toleration, to quiet and unite all men's minds."

[2] Leclerc, *Bibliothèque Choisie,* tom. vi. p. 379.

About the same period commenced the intimacy between Newton and Locke, which forms so interesting a part of their biography. Of that memorable friendship some curious and instructive monuments have been preserved. One of these will more particularly interest mathematicians. It is a demonstration of the fundamental proposition in the *Principia*, and its principal corollary; and we presume that it must have been drawn out for the purpose of explaining the matter fully to Locke. Lord King informs us that the paper containing it is indorsed "Mr Newton, March 1689;" and thinks that it was communicated before the publication of the *Principia*. But however the indorsement may be accounted for, this is a mistake; the *Principia* having, as is well known, been published in 1687. The demonstration begins with three hypotheses, of which two are the first axioms or laws of motion, and the third is the first corollary to the third axiom in b. i. prop. 1 of the *Principia*. Then follows the important proposition of the radius-vector describing equal areas in equal times, being the well-known proposition first of the second section, and demonstrated in nearly the same manner in which it is there given. Next comes the first proposition of the third section, in substance, but given in the form of a theorem upon the law of attraction applied to bodies moving in elliptical orbits. The construction and demonstration differ materially from those contained in the *Principia;* and three lemmas are prefixed, the substance of one of which may be recognised in the early part of the demonstration given in the *Principia*, whilst it forms the subject of a note in the Jesuits' commentary on that proposition. These lemmas being expressed in a more explanatory form than those of the *Principia* usually are, we may hence conclude, that Newton's illustrious pupil had required him to state as plainly as possible the grounds of his fundamental doctrine.

But these things, however interesting to mathematicians, will not arrest the attention of the general reader so much as the very curious correspondence between Newton and Locke, which Lord King has given to the world. Part of this correspondence relates to the letter which Newton had addressed to Locke upon the famous verse in John (1 John, v. 7), and the controverted passage in Timothy (1 Tim. iii. 16). He had been desirous at one time to have his researches upon these texts published; but being anxious to avoid controversy, and aware of the virulence with which he would be attacked as soon as his theory became known, he begged Locke to get it translated into French and published on the Continent. Locke, therefore, sent the manuscript to his friend and correspondent Leclerc, without disclosing the name of the author, for the purpose of having it translated and published in Holland. But some time afterwards Newton appears to have become alarmed at the risk of being discovered; and on the 16th of February 1692, he addressed a letter to Mr Locke, in which he says, "Let me entreat you to stop the translation and impression so soon as you can; for I design to suppress them." Accordingly, Leclerc did not proceed with the publication, but retained the papers until Locke's death in 1704, and, never having been informed to whom they belonged, deposited them in the library of the Remonstrants, where they were found, and published in 1754. Other parts of Newton's correspondence relate to his opinions upon passages in the Prophecies, which appear to have engrossed a large share of his attention, especially after he had ceased to devote himself so unremittingly to science as he did in the early part of his life.

But the most singular part of this correspondence relates to that affecting passage in Newton's life, in which it appears that his great mind, whether from bodily ailment, some original morbid predisposition, or from too vast a burden being imposed upon it, had, for a season, been liable to aberrations. And, in the first place, we shall refer to the authority upon which this passage in the history of Newton's life rests; a fact of which so melancholy a confirmation is afforded by his correspondence with Mr Locke. In a manuscript diary of Huygens, preserved in the library of Leyden, there is a note, in which it is stated that, on the 29th of May 1694, a Scotchman of the name of Colin (or Collins) informed him, that, eighteen months before, Newton had become deranged, in consequence either of too severe application, or of distress occasioned by the loss of his papers, which were accidentally burned; that his alienation had first appeared in a conference with the archbishop; and that, having been confined by his friends, he gradually recovered, so as of late (that is, prior to the date of Colin's communication to Huygens) to have become capable of resuming his pursuits. This would carry back the period of his being taken ill to December 1692; and there is at Cambridge a manuscript letter of Mr de la Pryne, dated in February 1693, in which the well-known circumstance of the burning of the papers containing his calculations, by a lap-dog, is mentioned, and a statement added, that Newton "was so troubled thereat, that every one thought he would have run mad, and he was not himself for a month after."[1] These facts would seem to fix the winter of 1692–1693 as the period at which this malady commenced.

---

[1] This shows how wide of the truth is the common version of the anecdote, which gives it as a striking instance of Newton's extreme composure and patience, that he contented himself with exclaiming to the little dog, "Diamond, thou little knowest what mischief thou hast done!" The absurdity of this, and some other anecdotes of a similar kind, consists in the supposition upon which they all proceed, that Newton was raised above the ordinary impulses, feelings, and weaknesses of humanity. But there is no evidence of any kind to show that he was exempted from the common frailties of our nature, and some which goes to establish the contrary. In "patient thinking," no one, dead or living, ever approached him; but his temper could occasionally be ruffled, like that of any other man; and in such cases, it is highly improbable that excited feelings would find expression in a miserable scrap of sentiment. When provoked with Flamsteed, he called the astronomer royal "a puppy," just as any body else would have done in similar circumstances.

A degree of irritability and suspicion may, however, be discerned in his correspondence during the earlier part of the year 1692. The letter written to Mr Locke, concerning the papers which had been sent to Leclerc, betrays morbid feeling; and there is one respecting Mr Montague, afterwards Lord Halifax, which is tinged with very unmerited suspicions of that person. "Being fully convinced," says he, "that Mr Montague, upon an old grudge which I thought had been worn out, is false to me, I have done with him." Mr Montague had been his colleague in the representation of Cambridge; and having always had the highest esteem for Newton, obtained for him, a few years afterwards, the office of Master of the Mint. There is likewise another letter, dated in August of the same year, containing a good deal of suspicion insinuated against Mr Boyle. But these indications would have excited no rash observation, had they not been followed by the letters of the next year. In one dated in September 1693, addressed to Mr Locke, he says, "Being of opinion that you endeavoured to embroil me with women, and by other means, I was so much affected with it, as that when one told me you were sickly and would not live, I answered, 'twere better you were dead. I desire you to forgive me this uncharitableness. For I am now satisfied that what you have done is just, and I beg your pardon for my having hard thoughts of you for it, and for representing that you struck at the root of morality, in a principle you laid [down] in your book of ideas, and designed to pursue in another book, and that I took you for a Hobbist." Locke's answer is admirable; full of excellent and amiable feeling towards his illustrious friend, and, at the same time, breathing the dignity of a mind wholly unconscious of offence. It is dated at Oates, 5th of October 1693. "I have been, ever since I first knew you, so entirely and sincerely your friend," says Mr Locke, "and thought you so much mine, that I could not have believed what you tell me of yourself, had I had it from any body else. And though I cannot but be mightily troubled that you should have had so many wrong and unjust thoughts of me, yet, next to the return of good offices, such as from a sincere good will I have ever done you, I receive your acknowledgment of the contrary as the kindest thing you could have done me, since it gives me hopes I have not lost a friend I so much valued. After what your letter expresses, I shall not need to say anything to justify myself to you. I shall always think your own reflection on my carriage, both to you and all mankind, will sufficiently do that. Instead of that, give me leave to assure you, that I am more ready to forgive you than you can be to desire it; and I do it so freely and fully, that I wish for nothing more than the opportunity to convince you that I truly love and esteem you; and that I have still the same good will for you as if nothing of this had happened. To confirm this to you more fully, I should be glad to meet you anywhere; and the rather, because the conclusion of your letter makes me apprehend that it would not be wholly useless to you. But whether you think it fit or not, I leave wholly to you. I shall always be ready to serve you to my utmost, in any way you shall like, and shall only need your commands or permission to do it." The letter which this called forth from Newton shows plainly the unhappy state to which he must have been reduced. "The last winter," says he, "by sleeping too often by my fire, I got an ill habit of sleeping; and a distemper, which this summer has been epidemical, put me farther out of order, so that when I wrote you, I had not slept an hour a night for a fortnight together, and for five nights together not a wink. I remember I wrote to you, but what I said of your book I remember not." Here we have direct evidence that the mind of this illustrious man had been in a state of obscuration, and that the temporary darkness was beginning to be dispelled. These disclosures may also serve to explain the otherwise remarkable fact, that Newton had completed all his discoveries in science before attaining the age of forty-five, and that he did little or nothing after that, although he lived in the enjoyment of health forty years longer.

In 1695, Mr Locke was appointed a commissioner of trade and plantations. For this office, worth about L.1000 a year, he was indebted to the friendship of Lord Somers, who reposed great confidence in him, and paid much deference to his judgment in the practical details of politics. About the same time the bad state of the coin was such as to call for the attention of the government. The practical men, as they delight to call themselves, though they are often the most fanciful of speculators (only that their theory being founded on a partial view of a few facts, and therefore necessarily false, assumes the shape of detail), recommended as the obvious remedy an alteration of the standard; but, happily for the credit and the interest of the country, it had at that time ministers both honest and sagacious enough to pursue a different course. Lord Somers and Sir William Turnbull preferred the counsels of Mr Locke to those of Mr Lowndes and his practical friends, and the great measure of the recoinage was carried through. The difference between the embarrassments which affected the currency in the reign of William III. and those which have occurred in our own time, are well stated by Lord King in his Life of Locke. "The coin, at the period first mentioned, had been deteriorated by the frauds of individuals and the neglect of the public; but when the evil was felt, and the remedy pointed out, the parliament, notwithstanding the pressure of the war, and the false theories of the practical men of those days, applied the proper remedy at the proper time, before any great permanent debt had been incurred. In our own time, the depreciation of the currency was entirely to be attributed to the bank and the government. The paper-money of a banking company, without the one indispensable security against it, payment in specie on demand, was in an evil hour substituted in place of the king's lawful coin; and in order that the minister might avoid the imputation of being an unskilful financier, who borrowed money on unfavourable terms, a debt of unexampled magnitude was accumulated in a debased currency, to be ultimately discharged in specie at the full and lawful standard. It must be confessed, that by the tardy act of retributive justice, which was passed in 1819, the punishment inflicted upon the nation was in the exact proportion to the former deviations from good faith and sound principle; and we may at least hope that the severity of the penalty will in future prevent a repetition of the same folly."

The increasing infirmities of Mr Locke, arising from his asthmatic complaint, induced him, in 1700, to resign his seat at the board of trade, notwithstanding the pressing instances of Lord Chancellor Somers. He felt an invincible repugnance to retain the office when he found that, from the state of his health, he must leave a great portion of its duties unperformed. For the same reason, he declined a proposal of another and apparently a higher situation, made to him by the king himself, who sent for him to Kensington that he might persuade him to accept it. The air of London appears to have been unfavourable to his ailment; and he spent the last four years of his life at the seat of Sir Francis and Lady Masham, at Oates, in Essex, where he had occasionally resided during many preceding years. In this hospitable and friendly retreat, his chief occupation consisted in the study of the Scriptures, an employment in which he found so much gratification that he regretted not having devoted more of his time to it in the earlier part of his life. But, though thus occupied, his affection for his friends and his love of his country suffered no diminution. His correspondence, at this period, with his cousin Sir Peter, afterwards Lord Chancellor King, is full of the gentlest affection, mixed with his wonted sagacity, and breathing the warmest attachment to the liberties of his country.

In 1703, Locke suffered severely from the asthmatic complaint with which he had been so long afflicted; but though labouring under an incurable disorder, his natural cheerfulness never forsook him, and, whilst perfectly resigned to his own fate, he continued to the last deeply interested in the welfare of his friends. His literary occupation at this time was the study of, and preparation of a commentary on, St Paul's Epistles, afterwards published amongst his posthumous works. In October 1704, his malady had greatly increased. On the 27th of that month, Lady Masham, not finding him in his study as usual, went to his bedside, when he told her that the fatigue of getting up the day before had been too much for his strength, and that he never expected to rise again from his bed. He had now, he said, finished his career in this world, and in all probability would not outlive the night, certainly not survive beyond the next day or two. After taking some refreshment, he observed to those present that he wished them all happiness when he was gone. To Lady Masham, who remained with him, and whose kind attentions had soothed so many hours of hopeless suffering, he said that he thanked God he had passed a happy life, but that now he found that all was vanity; and he earnestly exhorted her to consider this life as only a preparation for a better and happier state hereafter. He would not suffer her to watch by him during the night, observing, that perhaps he might be able to sleep; but that if any change should happen, he would send for her. Having had no sleep in the night, he was taken out of bed, and carried into his study, where he slept for some time in his chair. When he awoke he desired to be dressed, and then heard Lady Masham read the Psalms, apparently with great attention, until, perceiving that his end drew near, he stopped her, and a few minutes afterwards expired, about three o'clock in the evening of the 28th of October, in the seventy-third year of his age.

It is difficult to say whether mankind have been more indebted to this illustrious man as a philosopher or as a politician. The publication of his great work, the Essay concerning Human Understanding, undoubtedly fixed an era in the history of intellectual science. On this subject, however, it is only necessary here to refer the reader to the First Preliminary Dissertation (Part ii. sect. i. p. 100, et seq.), where the highest attainments in philosophy, an eloquence worthy of Plato himself, and a cautious, discriminating sagacity, all happily combined, have been employed in the exposition of Locke's speculative labours. But his writings and his personal exertions in favour of liberty, and more especially of religious toleration, may truly be said to have produced a greater effect than can be ascribed to the efforts of perhaps any other individual who bore a part in the transactions of the important period immediately succeeding the Revolution. The true doctrines of toleration were first promulgated by him in their full extent; he asserted the principle in its greatest amplitude, that opinion is not a matter cognizable by the civil magistrate, and that belief, being the result of reason, is wholly independent of the will, and the subject neither of praise nor of censure, far less the object of punishment or reward. It is well known, indeed, that intolerance had not ceased at the Reformation; that the Protestant church had not put an end to persecution. The influence of the Reformation had, do doubt, been salutary in this, as in other respects; but persecution had been mitigated by very slow degrees; and, in its early stages, the reformed church was to the full as intolerant, and nearly as persecuting, as the hierarchy which it had supplanted. In proof of this, it is only necessary to refer to the numerous executions of Catholics, and even of Protestant dissenters, in the reign of Queen Elizabeth; executions which were not unfrequently accompanied by the most cruel tortures.[1] At a later period, the Episcopalian church of Scotland not only equalled, but even surpassed the cruelties of the older times; and the intolerance of the Presbyterians during the whole of the seventeenth century is too well known to require any particular exposition. It is from the era of the Revolution that we must date the establishment of that toleration which the Reformation had in no respect secured; and it has been reserved for our own times to carry the principles of Locke to their full extent, and to supply those deficiencies in the scheme of religious freedom which he and his coadjutors were unfortunately obliged to leave in their great work. In the matter of civil government, the obligations of mankind generally, and of his countrymen in particular, to the genius, the wisdom, and the sagacity of Locke, are not less conspicuous and important. He it was who not only exposed the folly, as well as injustice, of the slavish doctrines which had hitherto prevailed, but who placed upon a solid foundation the true principles of legislation and government.

All the works of this great man have been collected, and frequently reprinted in different forms. They consist of, 1. Three Letters upon Toleration, the first (in Latin) printed at London in 1689; 2. A Register of the Changes of the Air observed at Oxford, inserted in Mr Boyle's *General History of the Air*, 1692; 3. New Method for a Commonplace Book, 1686; 4. Essay concerning Human Understanding, 1690; 5. Treatises of Civil Government, 1690, 1694, and 1698; 6. Some Considerations of the Consequences of lowering the Interest and raising the Value of Money, 1691 and 1695; 7. Observations on a printed paper entitled *For coining Silver Money in England;* 8. Farther Observations concerning the raising the Value of Money; 9. Some Thoughts concerning Education, 1695; 10. The Reasonableness of Christianity, 1695; 11. Vindication of the Reasonableness, 1695; 12. A Second Vindication, 1696; 13. A Letter to the Bishop of Rochester, 1697; 14. Reply to the Bishop of Rochester, 1697; 15. Reply, in answer to the Bishop's second Letter, 1698; 16. Posthumous works of Mr John Locke, containing, Of the Conduct of the Understanding, intended as a supplement to the Essay, An examination of Malebranche's Opinion that we see all things in God, A Discourse of Miracles, part of a Fourth Letter on Toleration, Memoirs relating to the Life of Anthony first Earl of Shaftesbury, &c. At his death he left several manuscripts, from which his executors, Sir Peter King and Mr Anthony Collins, published, in 1705, his paraphrase and notes upon St Paul's Epistle to

---

[1] Of the persecuting spirit of that age it is scarcely possible for us to form any adequate conception. Fox, the martyrologist, addressed to Queen Elizabeth an earnest entreaty that she would be pleased to put a stop, not to persecution, but only to the *burning* of the Anabaptists in Smithfield. He seems to have thought it a great deal too much to seek that no punishments, even no capital punishments, should be inflicted for the crime of dissent; he merely begs that such "horrors" as burning should be disallowed. "There are chains," says Fox, "there is exile, there are branding and stripes, and even the gibbet; this alone (burning) I earnestly deprece." It is only one form of cruelty that shocks the soul of the martyrologist; he seems to have felt great "horror" at the infliction of death by fire; but he makes no objection to the application of such other specifics, in case of non-conformity or dissent, as chains, exile, branding, stripes, and even the gallows itself. Disallow fire, and he is satisfied. What a picture does this exhibit of the glorious reign of "the good Queen Bess!"

the Galatians, which were soon followed by those upon the Corinthians, Romans, and Ephesians, with an Essay prefixed for the understanding of St Paul's Epistles, by consulting St Paul himself. In 1708 were likewise published some familiar letters which passed between Mr Locke and several of his friends. (See Lord King's *Life of John Locke*, London, 1829, in 4to; and particularly the *Edinburgh Review*, vol. l. p. 1, et seq.) (A.)

LOCLE, a market-town of the province of Valangin, in the canton of Neufchatel, in Switzerland. It is 1487 feet above the level of the sea, being situated in a deep valley of the Jura Mountains. It contains 489 houses, and 4670 inhabitants. It is remarkable as being the first place where a watch was made by John Ri, who taught the art to his neighbours, who have since continued the operation. Hosiery and thread-lace are now also made. Long. 6. 49. 35. E. Lat. 47. 3. 15. N.

LOCMINE, a town of France, in the department of Morbihan, and arrondissement of Pontivy. It contains 1700 inhabitants, but within the bounds of the parish there are 9500 persons.

LOCRI, or Locri Epizephyrii, in *Ancient Geography*, a town on the Ionian Sea, near the promontory Zephyrium. The inhabitants are said to be the first who used a code of written laws.

LOCUS Geometricus, a line by which a local or indeterminate problem is solved. A *locus* is a line, any point of which may equally solve an indeterminate problem. Thus, if a right line suffice for the construction of the equation, it is called *locus ad rectum;* if a circle, *locus ad circulum;* if a parabola, *locus ad parabolam;* if an ellipsis, *locus ad ellipsin;* and so of the rest of the conic sections.

LOCUTIUS, in *Mythology*, the god of speech amongst the Romans, called by Livy *Anis Locutius.*

LOCUTORIUM, a hall or apartment in monasteries, where the monks and other religious persons met after dinner to converse.

LODDON, a market-town of the county of Norfolk, and hundred of its own name, 111 miles from London, and five from Bungay. The market is held on Saturday, but is inconsiderable. The population amounted in 1801 to 799, in 1811 to 937, in 1821 to 1038, and in 1831 to 1175.

LODEVE, an arrondissement of the department of the Hérault, in France, 522 square miles in extent. It comprehends five cantons, divided into seventy-five communes, containing 51,500 inhabitants. The chief place is the city of the same name, situated between two lofty mountains, at the foot of the Cevennes, on the river Ergue. It contains 840 houses, and 850 inhabitants. It is an ill-built but an industrious place, yielding, besides much wine, woollens, silks, and hats, olive oil, and brandy. Long. 3. 15. E. Lat. 43. 47. N.

LODGEMENT, in military affairs, a work made by the besiegers in some part of a fortification, after the besieged have been driven out, in order to maintain it, and cover themselves from the enemy's fire.

LODI, a delegation or province within the government of Milan, in the Austrian kingdom of Venetian Lombardy. It is surrounded by the other Austrian provinces of Bergamo, Cremona, Pavia, and Milan. It extends over 709 square miles, and comprehends two cities, eight market-towns, 189 villages, with 27,726 houses, and 195,485 inhabitants. It is well watered by various streams, some running to the Po, and others to the Adda; and the whole is fertile. The district around the city comprehends some of the richest lands of the Austro-Italian dominions. It is chiefly a rich pasture, upon which the largest herds of cows are fed. The dairies are managed with much skill and attention, and yield the greater part of that rich cheese known in most parts of Europe by the name Parmesan, but which in Italy is commonly described by the name of this city, as *Fromaggio Lodisana.* The capital is the city of the same name, situated on the river Adda, over which is a bridge that was the scene of one of the most daring and successful events of the early years of Bonaparte's military career. It is an old, extensive city, the see of a bishop, and of the provincial courts of law. It contains a cathedral and nineteen other churches, and 1412 houses, with 17,812 inhabitants. There is a fine theatre, a royal college, and an institution of a collegiate kind for the education of females. The chief employment consists in spinning and weaving silk, and there are also some manufactures of earthenware and china. Long. 9. 25. 32. E. Lat. 45. 18. 31. N.

LOG, in the Jewish antiquities, a measure which contained a quarter of a cab, and consequently five sixths of a pint. There is mention made of a log (2 Kings, vi. 25) under the name of a *fourth part of a cab.* But in Leviticus the word log often signifies the measure of oil which lepers were to offer at the temple after they were cured of their disease. Dr Arbuthnot thinks that the log was a measure of liquids, the seventy-second part of the bath or ephah, and the twelfth part of the hin.

Log, a nautical term, signifying a small piece of timber, of a triangular, sectoral, or quadrantal figure, generally about a quarter of an inch thick, and five or six inches from the angular point to the circumference. It is balanced by a thin plate of lead, nailed to the arch, or circular side, so as to swim perpendicularly in the water.

Log-Line, a little cord or line, fastened to the log by means of two legs, one of which passes through a hole at the corner, and is knotted on the opposite side, whilst the other leg is attached to the arch by a pin fixed into another hole, so as to draw out occasionally. By these legs the log is suspended in equilibrio; and the line thus annexed to it is wound round a reel, fixed for that purpose in the gallery of the ship.

The use of the log and log-line is to keep account and make an estimate of the ship's way or distance run, which is done by observing the length of line unwound in half a minute's time, told by a half-minute glass; for so many knots as run out in that time, so many miles the ship sails in an hour. Thus, if there be four knots veered out in half a minute, the ship is computed to run four miles an hour. The author of this device for measuring the ship's way is not known; and no mention of it occurs till the year 1607, in an East India voyage published by Purchas; but from that time its name occurs in other voyages amongst his collections, and henceforward it was noticed both by our own authors and by foreigners; as by Gunter in 1623, Snellius in 1624, and by almost all the succeeding writers on navigation.

The log is a very precarious mode of computation, and must always be corrected by experience, much uncertainty arising from the motions of the ship, the winds of variable force, the friction of the reel, and the lightness of the log in the course of the current. See Navigation.

Perpetual Log, a machine so called by its inventor, Mr Gottlieb of London, is intended for keeping a constant and regular account of the rate of a ship's velocity in the interval of heaving the log.

Log-Board, a sort of table, divided into several columns, containing the hours of the day and night, the direction of the winds, the course of the ship, and all the material occurrences that happen during the twenty-four hours, or from noon to noon; together with the latitude by observation. From this table the officers of the ship are furnished with materials for compiling their journals.

Log-Book, a book into which the contents of the log-board are daily copied at noon, together with every circumstance deserving notice which happens to the ship, either at sea or in harbour.

LOGARITHMS.

I.—HISTORY OF LOGARITHMS.

THE labour and time required for performing the arithmetical operations of multiplication, division, and the extraction of roots, were at one time considerable obstacles to the improvement of various branches of knowledge, and in particular the science of astronomy. But about the end of the sixteenth century and the beginning of the seventeenth, several mathematicians began to consider by what means they might simplify these operations, or substitute for them others more easily performed. Their efforts produced some ingenious contrivances for abridging calculations; but of these the most complete by far was that of John Napier, baron of Merchiston, in Scotland, who invented a system of numbers called *logarithms,* so adapted to the numbers to be multiplied or divided, that these being arranged in the form of a table, each opposite the number called its logarithm, the product of any two numbers in the table was found opposite that formed by the addition of their logarithms; and, on the contrary, the quotient arising from the division of one number by another was found opposite that formed by the subtraction of the logarithm of the divisor from that of the dividend; and similar simplifications took place in the still more laborious operations of involution and evolution. But before we proceed to relate more particularly the circumstances of this invention, it will be proper to give a general view of the nature of logarithms, and of the circumstances which render them of use in calculation.

Let there be formed two series of numbers, the one constituting a geometrical progression, whose first term is unity or 1, and the common ratio any number whatever; and the other an arithmetical progression, whose first term is 0, and the common difference also any number whatever; for example, suppose the common ratio of the geometrical series to be 2, and the common difference of the arithmetical series 1, and let them be written thus:

Geom. Prog.		Arith. Prog.
1	-	0
2	-	1
4	-	2
8	-	3
16	-	4
32	-	5
64	-	6
128	-	7
256	-	8
512	-	9
1024	-	10
2048	-	11
4096	-	12
&c.		&c.

Here the terms in the arithmetical series are called the *logarithms* of the corresponding terms of the geometrical series; that is, 0 is the logarithm of 1, and 1 is the logarithm of 2, and 2 is the logarithm of 4, and 3 that of 8, and so on.

From the manner in which the two series are related to each other, it will readily appear by induction that the logarithms of the terms of the geometrical series have the two following properties:

1. The sum of the logarithms of any two numbers or terms in the geometrical series is the logarithm of that number, or term of the series, which is equal to their product.

For example, let the terms of the geometrical series be 4 and 32; the corresponding terms of the arithmetical series (that is, their logarithms) are 2 and 5: now the product of the numbers is 128, and the sum of their logarithms is 7; and it appears by inspection of the two series, that the latter number is the logarithm of the former, agreeing with the proposition we are illustrating. In like manner, if the numbers or terms of the geometrical series be 16 and 64, the logarithms of which are 4 and 6, we find from the table that $10=4+6$ is the logarithm of $1024=16\times 64$; and so of any other numbers in the table.

2. The difference of the logarithms of any two numbers or terms of the geometrical series is the logarithm of that term which is the quotient arising from the division of the one number by the other.

Take, for example, the terms 128 and 32, the logarithms of which are 7 and 5; the greater of these numbers divided by the less is 4, and the difference of their logarithms is 2; and by inspecting the two series, this last number will be found to be the logarithm of the former. In like manner, if the terms of the geometrical series be 1024 and 16, the logarithms of which are 10 and 4, we find that $1024\div 16=64$, and that $10-4=6$; now, in the table, the latter number, viz. 6, is the logarithm of the former, 64.

These two properties of logarithms, the second of which indeed is an immediate consequence of the first, enable us to find with great facility the product or the quotient of any two terms of a geometrical series to which there is adapted an arithmetical series, so that each number has its logarithm opposite to it, as in the preceding short table. For it is evident, that to multiply two numbers, we have only to add their logarithms, and opposite to that logarithm which is the sum we shall find the product required. Thus, to multiply 16 by 128; to 4 the logarithm of 16, add 7 the logarithm of 128, and opposite the sum 11, we find 2048, the product sought. On the other hand, to divide any number in the table by any other, we subtract the logarithm of the divisor from that of the dividend, and look for the remainder among the logarithms, and opposite to it we find the number sought. Thus, to divide 2048 by 128; from 11, the logarithm of 2048, we subtract 7, the logarithm of 128, and opposite the remainder 4, we find 16, the quotient sought.

Let us now suppose any number of geometrical means to be interposed between each two adjoining terms of the preceding geometrical series, and the same number of arithmetical means between every two adjoining terms of the arithmetical series; then, as the results will still be a geometrical and an arithmetical series, the interpolated terms of the latter will be the logarithms of the corresponding terms of the former, and the two new series will have the very same properties as the original series.

If we suppose the number of interpolated means to be very great, it will follow that among the terms of the resulting geometrical series, some one or other will be found nearly equal to any proposed number whatever. Therefore, although the preceding table exhibits the logarithms of 1, 2, 4, 8, 16, &c. but does not contain those of the intermediate numbers, 3, 5, 6, 7, 9, 10, &c. yet it is easy to conceive that a table might be formed by interpolation which should contain, amongst the terms of the geometrical series, all numbers whatever to a certain extent (or at least others very nearly equal to them), together with their logarithms. If such a table were constructed, or at least if such terms of the geometrical progression were found, together with their logarithms, as were either accurately equal to, or coincided nearly with, all numbers within certain limits (for example, between 1 and 100,000), then, as often as we had occasion to multiply or divide any numbers contained in that table, we might evidently obtain the products or quotients by the simple operations of addition and subtraction.

The first invention of logarithms has been attributed by some to Longomontanus, and by others to Juste Byrge, two mathematicians contemporary with Napier; but there is no reason to suppose that either of these anticipated him, for Longomontanus never published any thing on the subject, although he lived thirty-three years after Napier had made known his discovery; and as to Byrge, he is indeed known to have printed a table containing an arithmetical and a geometrical progression written opposite to each other, so as to form in effect a system of logarithms of the same kind as those invented by Napier, without however explaining their nature and use, although it appears from the title he intended to do so, but was probably prevented by some cause unknown to us. But this work was not printed till 1620, six years after Napier had published his discovery, namely, in 1614, in a book entitled *Mirifici Logarithmorum Canonis Descriptio;* but he reserved the construction of the numbers till the opinion of the learned concerning his invention should be known. It is therefore with good reason that Napier is now universally considered as the first, and most probably the only inventor. His work contains a table of the natural sines and cosines, and their logarithms, for every minute of the quadrant, as also the differences between the logarithmic sines and cosines, which are in effect the logarithmic tangents. There is no table of the logarithms of numbers; but precepts are given, by which they, as well as the logarithmic tangents, may be found from the table of natural and logarithmic sines.

In explaining the nature of logarithms, Napier supposes some determinate line which represents the radius of a circle to be continually diminished, so as to have successively all possible values, and thus to be equal to every sine, one after another, throughout the quadrant. And he supposes this diminution to be effected by a point moving from one extremity towards the other extremity (or rather some point very near it), with a motion that is not uniform, but decreases gradually in such a manner, that if the whole time between the beginning and the end of the motion be conceived to be divided into a very great number of equal portions, the decrements taken away in each of these shall be to one another as the respective remainders of the line. According to this mode of conceiving the line to decrease, it is easy to show that at the end of any successive equal intervals of time from the beginning of the motion, the portions of the line which remain will constitute a decreasing geometrical progression.

Again, he supposes another line to be generated by a point which moves along it equably, or which passes over equal intervals of it in equal times. Thus the portions of the line generated at the end of any equal successive intervals of time from the beginning of the motion will form a series of quantities in arithmetical progression. Now if the two motions be supposed to begin together, the remainders of the one line at the end of any equal intervals of time will form a series of quantities in geometrical progression, while the corresponding portions generated of the other line will constitute a series in arithmetical progression, so that the latter will be the logarithms of the former. And as the terms of the geometrical progression decrease continually from radius, which is the greatest term, to 0, while the terms of the corresponding arithmetical progression increase from 0 upwards, according to Napier's system the logarithm of radius is 0, and the logarithms of the sines from radius down to 0 are a series of numbers increasing from 0 to infinity.

The velocities or degrees of quickness with which the motions commence may have to each other any ratio whatever, and by assuming different ratios we obtain different systems of logarithms. Napier supposed the initial velocities to be equal; but the system of logarithms produced in consequence of this assumption having been found to have some disadvantages, it has been long superseded by a more convenient one, as we shall presently have occasion to explain.

Napier's work having been written in Latin, was translated into English by Mr Edward Wright, an ingenious mathematician of that period, and inventor of the principles of what is commonly though erroneously called *Mercator's sailing.* The translation being sent to Napier for his perusal, was returned with his approbation, and with the addition of a few lines, intimating that he intended to make some alterations in the system of logarithms in a second edition. Mr Wright died soon after he received back his translation; but it was published after his death in 1616, accompanied with a dedication by his son to the East India Company, and a preface by Henry Briggs, who afterwards distinguished himself by improving the form or system of logarithms. Mr Briggs likewise gave in this work the description and draught of a scale which had been invented by Wright, as also various methods of his own for finding a logarithm to a given number, and a number to a given logarithm, by means of Napier's table, the use of which had been attended with some inconvenience, on account of its containing only such numbers as were the natural sines to every minute of the quadrant and their logarithms. There was an additional inconvenience in using the table, arising from the logarithms being partly positive and partly negative. The latter of these was, however, well remedied by John Speidell in his *New Logarithms*, first published in 1619, which contained the sines, cosines, tangents, cotangents, secants, and cosecants, and given in such a form as to be all positive; and the former was still more completely removed by an additional table, which he gave in the sixth impression of his work in 1624, and which contained the logarithms of the integers 1, 2, 3, 4, &c. to 1000, together with their differences and arithmetical complements, &c. This table, which is of great use in finding fluents, is commonly called *hyperbolic logarithms*, because the numbers serve to express the areas contained between a hyperbola and its asymptote, and limited by ordinates drawn parallel to the other asymptote. This name, however, is certainly improper, as the same spaces may represent the logarithms of any system whatever.

In 1619, Robert Napier, son of the inventor of logarithms, published a second edition of his father's *Logarithmorum Canonis Descriptio;* and, along with this, the promised *Logarithmorum Canonis Constructio*, and other pieces written by his father and Mr Briggs. An exact copy of the same two works in one volume was also printed in 1620 at Lyons in France. In 1618 or 1619, Benjamin Ursinus, mathematician to the elector of Brandenburg, published Napier's tables of logarithms in his *Cursus Mathematicus*, to which he added some tables of proportional parts; and in 1624 he printed his *Trigonometria*, with a table of natural sines, and their logarithms of the Napierian kind and form, to every ten seconds of the quadrant.

In the same year, 1624, the celebrated John Kepler published, at Marpurg, logarithms of nearly the same kind, under the title of *Chilias Logarithmorum ad totidem Numeros Rotundos, præmissa Demonstratione legitima Ortus Logarithmorum eorumque Usus*, &c.; and in the following year he published a supplement to this work. In the preface to this last he says, that several of the professors of mathematics in Upper Germany, and more especially those who were advanced in years, and grown averse to new methods of reasoning which carried them out of their old principles and habits, doubted whether Napier's demonstration of the property of logarithms was perfectly true, and whether the application of them to trigonometrical calculations might not be unsafe, and lead the calculator who should trust in them to erroneous results; and in either case, whether the doctrine were true or not, they scarcely considered Napier's demonstration of it as legitimate and satisfactory. This opinion induced Kepler to compose the above-mentioned work, in which the whole doctrine is treated in a manner strictly geometrical, and free from the considerations of motion to which those elderly Germans had objected.

On the publication of Napier's Logarithms, Mr Henry Briggs, some time professor of geometry in Gresham College, London, and afterwards Savilian professor of geometry at Oxford, applied himself with great earnestness to the study and improvement of them. From the particular view which Napier took of the subject, and the manner in which he conceived logarithms to be generated, it happened that in his system the logarithms of a series of numbers which increased in a decuple ratio (as 1, 10, 100, 1000, &c.) formed a decreasing arithmetical series, whose common difference was 2·3205851. But it occurred to Briggs that it would be better and more conformable to the received decimal notation, to adopt a system in which the logarithms of the terms of such a geometrical series should differ from each other by unity or 1. This idea Briggs communicated to the public in his lectures, and also to Napier himself. He even went twice to Edinburgh to converse with him on the subject; and, on his first visit, Napier said that he had also formerly thought of the same improvement, but that he chose to publish the logarithms he had previously calculated, till such time as his health and convenience would allow him to make others more commodious. And whereas, in the change which Briggs proposed, it was intended to make the logarithms of the sines to increase from 0 (the logarithm of radius) to infinity, whilst the sines themselves should decrease, it was suggested to him by Napier that it would be better to make them increase, so that 0, instead of being the logarithm of radius, should be the logarithm of 1, and that 100,000, &c. should be the logarithm of radius. This Briggs admitted would be an improvement; and having changed the numbers he had already calculated so as to make them suit Napier's modification of his plan, he returned with them next year to Edinburgh, and submitted them to his perusal.

It appears, therefore, that whether Napier or Briggs was the inventor of this improved system of logarithms which has since been universally adopted, Napier had suggested to begin with the low number 1, and to make the logarithms, or the artificial numbers, as he had always called them, to increase with the natural numbers, instead of decreasing; which, however, made no alteration in the figures, but only in their affections or signs, changing them from negative to positive.

On Briggs's return from Edinburgh, in 1617, he printed the first thousand logarithms to eight places of figures, besides the index, with the title of *Logarithmorum Chilias prima;* but these seem not to have been published till after the death of Napier, for in his preface he expresses a hope that the circumstances which led to a change in the system would be explained in Napier's posthumous work, about to appear. But although Napier had intimated in a note he had given in Wright's translation of the *Canon Mirificus*, as well as in his *Rabdologia*, printed in 1617, that he intended to alter the scale, yet he does not state that Briggs was the first to think of this improvement, or to publish it. And as nothing was said on this point in Napier's posthumous work published in 1619 by his son, Briggs took occasion, in his *Arithmetica Logarithmica*, to assert his claims to the improvement which he had carried into execution. But he has by no means proved that he himself, and not Napier, was the first who had thought of such improvements.

In 1620, Mr Edmund Gunter published his *Canon of Triangles*, which contains the artificial or logarithmic sines and tangents to every minute to seven places of figures besides the index, the logarithm of radius being 10. These logarithms are of the kind which had been agreed upon between Napier and Briggs, and they were the first tables of logarithmic sines and tangents that were published of this sort. Gunter also, in 1623, reprinted the same in his book *De Sectore et Radio*, together with the *Chilias prima* of Briggs; and in the same year he applied the logarithms of numbers, sines, and tangents, to straight lines drawn upon a ruler. This instrument is now in common use for navigation and other purposes, and is commonly called *Gunter's Scale.*

The discoveries in logarithms were carried to France by Mr Edmund Wingate, but not first of all, as he says in the preface to his book. He published at Paris in 1624 two small tracts in French upon logarithms, which were reprinted with improvements at London in 1626.

In the year 1624, Briggs published his *Arithmetica Logarithmica*, a stupendous work, considering the short time he had been in preparing it. He there gives the logarithms of 30,000 natural numbers to fourteen places of figures, besides the index; namely, from 1 to 20,000, and from 90,000 to 100,000, together with the differences of the logarithms. He also gives an ample treatise on their construction and use, and he earnestly solicits others to undertake the computation of the intermediate numbers, offering to give instructions, and paper ready ruled for that purpose, to any person inclined to contribute to the completion of so valuable a work. By this invitation, he had hopes of collecting materials for the logarithms of the intermediate 70,000 numbers, whilst he should employ his time upon the Canon of Logarithmic Sines and Tangents, and so carry on both works at once.

Soon after this, Adrian Vlacq or Flack of Gouda, in Holland, completed the intermediate 70 chiliads, and republished the *Arithmetica Logarithmica* in 1627 and 1628, with these intermediate numbers, making in all the logarithms of all numbers to 100,000, but only to 10 places of figures. To these was added a table of artificial sines, tangents, and secants, to every minute of the quadrant.

Briggs himself lived also to complete a table of logarithmic sines and tangents, to the 100th part of every degree to fourteen places of figures, besides the index, together with a table of natural sines to the same parts to fifteen places, and the tangents and secants of the same to ten places, with the construction of the whole. But death prevented him from completing the application and uses of them. However, when dying, he committed this to his friend Henry Gellibrand, who accordingly added a preface, and the application of the logarithms to plane and spherical trigonometry. The work was called *Trigonometria Britannica*, and was printed at Gouda in 1633, under the care of Adrian Vlacq, who in the same year printed his own *Trigonometria Artificialis, sive Magnus Canon Triangulorum Logarithmicus ad Decadas Secundorum Scrupulorum Constructus.* This contains the logarithmic sines and tangents to 10 places of figures, with their differences for every ten seconds in the quadrant. It also contains Briggs's table of the first 20,000 logarithms to ten places, besides the index, with their differences; and to the whole is prefixed a description of the tables and their applications, chiefly extracted from Briggs's *Trigonometria Britannica* just mentioned.

Gellibrand also published, in 1635, *An Institution Trigonometrical,* containing the logarithms of the first 10,000 numbers, with the natural sines, tangents, and secants, and the logarithmic sines and tangents, for degrees and minutes; all to seven decimal places.

The writers whose works we have hitherto noticed were for the most part computors of logarithms. But the system best adapted to practice being now well ascertained, and the labour of constructing the table accomplished, succeeding writers on the subject have had little more to do than to give the tables in the most convenient form. It is true, that in consequence of the numerous discoveries which were afterwards made in mathematics, particularly in the doctrine of series, great improvements were made in the method of computing logarithms; but these, for the most part, came too late to be of use in the actual construction of the tables, although they might be applied with advantage to verify calculations previously performed by methods much more laborious, and to detect various errors which had crept into the numbers.

As it is of importance that such as have occasion to employ logarithms should know what works are esteemed for their extent and accuracy, we shall mention the following:

Sherwin's *Mathematical Tables,* in 8vo. These contain the logarithms of all numbers to 101,000; and the sines, tangents, secants, and versed sines, both natural and logarithmic, to every minute of the quadrant. The third edition, printed in 1742, which was revised by Gardiner, is esteemed the most correct; but, in the fifth edition, the errors are so numerous, that no dependence can be placed on it.

Gardiner's Tables of Logarithms for all numbers to 101,000, and for the sines and tangents to every ten seconds of the quadrant; also for the sines of the first 72 minutes to every single second, &c. This work, which is in quarto, was printed in 1742, and is held in high estimation for its accuracy. An edition of the same work, with some additions, was printed in 1770, at Avignon, in France; and another by Callet at Paris in 1783, with farther improvements. The tables in both are to seven places of figures.

Hutton's *Mathematical Tables,* containing common, hyperbolic, and logistic logarithms, &c. and much valuable information respecting the history of logarithms, and other branches of mathematics connected with them.

Taylor's *Table of Logarithmic Sines and Tangents to every second of the quadrant;* to which is prefixed an able introduction by Dr Maskelyne, and a table of logarithms from 1 to 100,000, &c. This is a most valuable work; but being a large quarto volume, and rather expensive, it is less accessible than the preceding, which is an octavo, at a moderate price.

Tables portatives des Logarithmes, contenant les Logarithmes des nombres depuis 1 *jusqu'à* 108,000; *les logarithmes des sinus et tangentes, de seconde en seconde pour les cinq premiers degrés, de dix en dix secondes pour tous les degrés du quart de cercle, et suivant la nouvelle division centésimale de dix-millième en dix millième,* &c. par Callet. This work is in octavo, and printed in stereotype by Didot.

There are various smaller sets of tables; but probably the most accurate of all are those which Professor Babbage has produced with his very ingenious calculating machine, which has enabled him to detect a variety of errors in former tables. But, what is rather amusing, on examining a set of tables printed in the Chinese character, and which, like every Chinese invention, were older than the deluge, Mr Babbage found they contained precisely the same errors as those of Vlacq did; thus proving, as had long been suspected, from what source those original inventors had derived their logarithms.

In addition to these, it is proper that we should notice a stupendous work relating to logarithms, originally suggested by the celebrated Carnot, in conjunction with Prieur de la Côte d'Or, and Brunet de Montpellier, about the beginning of the French revolution. This enterprise was committed in 1794 to the care of Baron de Prony, a mathematician of great eminence, who was *not only to compose tables which should leave nothing to be desired with respect to accuracy, but to make them the most extended and most striking monument of calculation ever executed or imagined.* Two manuscript copies of the work, composed of seventeen volumes large folio, contained, besides an introduction,

1. The natural sines for each 10,000th part of the quadrant, calculated to twenty-five places of decimals, to be published with twenty-two decimals and five columns of differences.
2. The logarithms of these sines, calculated to fourteen decimals, with five columns of differences.
3. The logarithms of the ratios of the sines to the arcs for the first five thousand 100,000th parts of the quadrant, calculated to fourteen decimal places, with three columns of differences.
4. The logarithms of the tangents corresponding with the logarithms of the sines.
5. The logarithms of the ratios of the tangents to the arcs, calculated like those of the third article.
6. Logarithms of numbers from 1 to 100,000, calculated to nineteen places of decimals.
7. The logarithms of numbers from 100,000 to 200,000, calculated to twenty-four decimals, in order to be published to twelve decimals and three columns of differences.

The printing of this work, though begun by the French government, was afterwards suspended.

II.—NATURE OF LOGARITHMS, AND THEIR CONSTRUCTION.

We have already shown that the properties of logarithms are deducible from those of two series, the terms of one of which form a geometrical progression, and those of the other an arithmetical progression; and as this manner of treating the subject is simple, it is perhaps the best adapted of any to such of our readers as have not pursued the study of mathematics to any great extent. We shall now show how, from the same principles, the logarithm of any proposed number may be found, as was done by the earlier computers, though it is far from affording the easiest mode of forming a table.

The first step to be taken in constructing a system of logarithms is to assume the logarithm of some determinate number, besides that of unity or 1, which must necessarily be 0. From the particular view which Napier first took of the subject, he was led to assume unity for the logarithm of the number 2·718282, by which it happened that the logarithm of 10 was 2·302585; and this assumption being made, the form of the system became determinate, and the logarithm of every number fixed to one particular value.

It was, however, soon observed, that it would be better to assume unity for the logarithm of 10, instead of making it the logarithm of 2·718282, as in Napier's first system; and hence the logarithms of the terms of the geometrical progression

$$1, \quad 10, \quad 100, \quad 1000, \quad 10{,}000, \ \&c.$$

were necessarily fixed to the corresponding terms of this arithmetical progression,

$$0, \quad 1, \quad 2, \quad 3, \quad 4, \ \&c.$$

That is, the logarithm of 1 being 0, and that of 10 being 1, the logarithm of 100 is 2, that of 1000 is 3, and so on.

The logarithms of the terms of the progression 1, 10, 100, 1000, &c. being thus determined; in order to form the logarithms of the numbers between 1 and 10, and between 10 and 100, and so on, we must conceive a very great number of geometrical means to be interposed between each two adjoining terms of the preceding geometrical series, and as many arithmetical means between the corresponding terms of the arithmetical series; then, like as the terms of the arithmetical series 0, 1, 2, 3, &c. are the logarithms of the corresponding terms of the geometrical series 1, 10, 100, 1000, &c. the interpolated terms of the former will also be the logarithms of the corresponding interpolated terms of the latter. Now, by supposing the number of means interposed between each two terms of the geometrical series to be sufficiently great, some one or other of them may be found which will be very nearly equal to any proposed number. Hence, to find the logarithm of such a number, we have only to seek for one of the interpolated means which is very nearly equal to it, and to take the logarithm of that mean as a near value of the logarithm required.

As a particular example, let it be required to find the logarithm of 5, according to Briggs's system.

First step of the process.—The number 5 is between 1 and 10, the logarithms of which we already know to be 0 and 1: Let a geometrical mean be found between the two former, and an arithmetical mean between the two latter. The geometrical mean will be the square root of the product of the numbers 1 and 10, which is 3·162277; and the arithmetical mean will be half the sum of the logarithms 0 and 1, which is 0·5; therefore the logarithm of 3·162277 is 0·5. But as the mean thus found is not sufficiently near the proposed number, we must proceed with the operation as follows:

Second step.—The number 5, whose logarithm is sought, is between 3·162277, the mean last found, and 10, the logarithms of which we know to be 0·5 and 1; we must now find a geometrical mean between the two former, and an arithmetical mean between the two latter. The one of these is $\sqrt{(3{\cdot}162277 \times 10)} = 5{\cdot}623413$, and the other is $\frac{1 + 0{\cdot}5}{2} = 0{\cdot}75$, the logarithm of 5·623413.

Third step.—We have now obtained two numbers, namely, 3·162277 and 5·623413, one on each side of 5, together with their logarithms 0·5 and 0·75; we therefore, proceeding as before, find the geometrical mean, or $\sqrt{(3{\cdot}162277 \times 5{\cdot}623413)}$, to be 4·216964, and the arithmetical mean $\frac{0{\cdot}5 + 0{\cdot}75}{2} = 0{\cdot}625$, the logarithm of 4·216964.

Fourth step.—We proceed in the same manner with the numbers 4·216964, and 5·623413 (one of which is less and the other greater than 5), and their logarithms 0·625 and 0·75, and find a new geometrical mean, viz. 4·869674, and the corresponding arithmetical mean or logarithm 0·6875.

We must go on in this way till we have found twenty-two geometrical means, and as many corresponding arithmetical means or logarithms. And that we may indicate how these are found from each other, let the numbers 1 and 10 be denoted by A and B, and their geometrical means taken in their order by C, D, E, &c. then the results of the successive operations will be as in the following table:

	Numbers.	Logarithms.
A =	1·000000	0·0000000
B =	10·000000	1·0000000
C = $\sqrt{AB}$ =	3·162277	0·5000000
D = $\sqrt{BC}$ =	5·623413	0·7500000
E = $\sqrt{CD}$ =	4·216964	0·6250000
F = $\sqrt{DE}$ =	4·869674	0·6875000
G = $\sqrt{DF}$ =	5·232991	0·7187500
H = $\sqrt{FG}$ =	5·048065	0·7031250
I = $\sqrt{FH}$ =	4·958069	0·6953125
K = $\sqrt{HI}$ =	5·002865	0·6992187
L = $\sqrt{IK}$ =	4·980416	0·6972656
M = $\sqrt{KL}$ =	4·991627	0·6982421
N = $\sqrt{KM}$ =	4·997242	0·6987304
O = $\sqrt{KN}$ =	5·000052	0·6989745
P = $\sqrt{NO}$ =	4·998647	0·6988525
Q = $\sqrt{OP}$ =	4·999350	0·6989135
R = $\sqrt{OQ}$ =	4·999701	0·6989440
S = $\sqrt{OR}$ =	4·999876	0·6989592
T = $\sqrt{OS}$ =	4·999963	0·6989668
V = $\sqrt{OT}$ =	5·000008	0·6989707
W = $\sqrt{TV}$ =	4·999984	0·6989687
X = $\sqrt{WV}$ =	4·999997	0·6989697
Y = $\sqrt{VX}$ =	5·000003	0·6989702
Z = $\sqrt{XY}$ =	5·000000	0·6989700

As the last of these means, viz. Z, agrees with 5, the proposed number, as far at least as the sixth place of decimals, we may safely consider them as very nearly equal, and therefore their logarithms very nearly equal; that is, the logarithm of 5 will be 0·6989700 nearly.

In performing the operations indicated in the preceding table, it is necessary to find the geometrical means at the beginning to many more figures than are here put down, in order to insure at last a result true to 7 decimal places. Thus it appears that the labour of computing logarithms by this method is indeed very great. It is, however, that which was employed by Briggs and Vlacq in the original construction of logarithms; but since their time more easy methods have been found, some of which we shall presently have occasion to explain; and a still easier method by Sir John Leslie will be found at the end of this article.

The logarithm of any number whatever may be found by a series of calculations similar to that just explained. But in constructing the table it would only be necessary to have recourse to this method in calculating the logarithms of prime numbers; for as often as the logarithm of a number which was the product of other numbers, whose logarithms were known, was required, it would be immediately obtained by adding together the logarithms of its factors. On the contrary, if the logarithm of the product of two numbers were known, and also that of one of its factors, the logarithm of the other factor would be obtained from these, by simply taking their difference.

From this last remark it is obvious, that having now found the logarithm of 5, we can immediately find that of 2; for since 2 is the quotient of 10 divided by 5, its logarithm will be the difference of the logarithms of 10 and 5; now the logarithm of 10 is 1, and that of 5 is 0·6989700, therefore the logarithm of 2 is 0·3010300.

Having thus obtained the logarithms of 2 and 5, in addition to those of 10, 100, 1000, &c. we may thence find the logarithms of innumerable other numbers. Thus, because $4 = 2 \times 2$, the logarithm of 4 will be the logarithm of 2 added to itself, or will be twice the logarithm of 2. Again, because $5 \times 10 = 50$, the logarithm of 50 will be the sum of the logarithms of 5 and 10. In this manner it is evident we may find the logarithms of $8 = 2 \times 4$, of $16 = 2 \times 8$, of $25 = 5 \times 5$, and of as many more such numbers as we please.

Besides the view we have hitherto taken of the theory of logarithms, there are others under which it has been presented by different authors. Some of these we proceed to explain, beginning with that in which they are defined to be the *measures of ratios;* but to see the propriety of this definition, it must be understood what is meant by the measure of a ratio.

Nature of Logarithms.

According to the usual definition of a compound ratio, if there be any number of magnitudes A, B, C, D, in continued proportion, the ratio of the first, A, to the third, C, is considered as made up of two ratios, each equal the ratio of the first, A, to the second, B. And in like manner the ratio of the first, A, to the fourth, D, is considered as made of three ratios, each equal the same ratio of the first to the second, and so on. Thus, to take a particular example in numbers, because the ratio of 81 to 3 may be considered as made up of the ratio of 81 to 27, and of 27 to 9, and of 9 to 3, which three ratios are equal among themselves, the ratio of 81 to 3 will be triple that of 9 to 3; and in like manner the ratio of 27 to 3 will be double that of 9 to 3. Also, because the ratios of 1000 to 100, 100 to 10, 10 to 1, are all equal, the ratio of 1000 to 1 will be three times as great as that of 10 to 1; and the ratio of 100 to 1 will be twice as great; and so on.

Taking this view of ratios, and considering them as a particular species of quantities, made up of others of the same kind, they may evidently be compared with each other in the same manner as we compare lines or quantities of any kind whatever. And as, when estimating the relative magnitude of two quantities, two lines, for example, if the one contains five such equal parts as the other contains seven, we say the one line has to the other the proportion of 5 to 7; so, in like manner, if two ratios be such, that the one can be resolved into five equal ratios, and the other into seven of the same ratios, we may conclude that the magnitude of the one ratio is to that of the other as the number 5 to the number 7; and a similar conclusion may be drawn, when the ratios to be compared are any multiples whatever of some other ratio.

Since lines and other quantities, which admit of no common measure, are said to be incommensurable to each other, the same will obviously happen to ratios; that is, there may be two ratios such, that into whatever number of equal ratios the one is divided, the other cannot possibly be exactly equal to a ratio composed of any integral number of these. We may, however, conceive the number of equal ratios into which the one is divided to be so great, that a certain number of them shall compose a ratio more nearly equal to the other ratio than by any assignable difference. Therefore, like as we can always find numbers which shall have among themselves, either accurately, or as nearly as we please, the same ratios as lines or other magnitudes have to each other, and which therefore may be taken as the measures or representatives of the lines; so also, corresponding to any system of ratios, there may be always found a series of numbers which will have the same proportions among themselves as the ratios have to each other, and which may in like manner be called the *measures of the ratios.*

Let us now suppose that unity, or 1, is assumed as the common consequent or second term of all ratios whatever; and that the ratio of 10 (or some particular number) to 1 is compounded of a very great number of equal ratios, as, for example, 1,000,000: then, as each of these will be very near the ratio of equality (for it will be the ratio of the first term to the second of a series consisting of one million and one continued proportionals, the first of which is 10 and last 1), it will follow, and is easy to conceive, that the ratios of all other numbers to unity will each be very nearly equal to some multiple of that small ratio. And by supposing the number of small equal ratios of which the ratio of 10 to 1 is composed, to be sufficiently great, the ratios of all other numbers to unity may be as nearly equal to ratios which are multiples of that small ratio, as we please. Let us still suppose, however, for the sake of illustration, that the number of small ratios contained in that of 10 to 1 is 1,000,000; then, as it may be proved that the ratio of 2 to 1 will be very nearly the same as a ratio composed of 301,030 of these, and that the ratio of 3 to 1 will be nearly equal to a ratio composed of 477,121 of them, and that the ratio of 4 to 1 will be nearly equal to a ratio composed of 602,060 of them, and so on; these numbers, viz. 1,000,000, 301,030, 477,121, and 602,060, or any other numbers proportional to them, will be the *measures* of the ratios of 10 to 1, 2 to 1, 3 to 1, and 4 to 1, respectively; and the same quantities will also be what have been called the *logarithms* of the ratios; for the word *logarithm*, if regard be had to its etymology, is λογῶν ἀριθμοὶ, or the numbers of small and equal ratios (or *ratiunculæ*, as they have been called) contained in the several ratios of quantities one to another.

We have, for the sake of illustration, assumed 1,000,000 as the measure of the ratio of 10 to 1, by which it happens, as already observed, that the measures of the ratios of 2 to 1, 3 to 1, &c. are 301,030 and 477,121 respectively; as, however, these measures are not absolute, but relative quantities, we may assume any other numbers whatever instead of these, provided they are proportional to them. Accordingly, we may assume 1 as the measure or logarithm of the ratio of 10 to 1; and then the logarithms of the ratios of 2 to 1, 3 to 1, &c. instead of being 301,030, 477,121, &c. will be ·301030 and ·477121, &c. respectively, that is, each will be one millionth of what it was before.

In Briggs's system, the logarithm of the ratio of 10 to 1, or, to speak briefly, the logarithm of 10, is unity; but we are at liberty to assume any number whatever, as that whose logarithm shall be unity. Napier, in consequence of his particular views, chose 2,718,282; and hence it happens that the logarithms of the ratios are expressed by different numbers in the two systems.

But, to show the identity of the properties of logarithms, as explained in the two different views now given of the subject, let A and B denote any two numbers. The ratio of their product to unity, that is, the ratio of $A \times B$ to 1, is compounded of the ratio of A to 1 and of B to 1; and consequently the logarithm of the ratio of $A \times B$ to 1 will equal the sum of the logarithms of the ratios of A to 1, and of B to 1; or, in other words, the logarithm of $A \times B$ will be the sum of the logarithms of A and B. Now, $\log. (A \times B) = \log. A + \log. B$, therefore, $\log. B = \log. (A \times B) - \log. A$. Let $\frac{C}{D}$ be substituted for B, and D for A, then (because $A \times B = D \times \frac{C}{D} = C$) we have $\log. \frac{C}{D} = \log. C - \log. D$.

Such is a short sketch of the theory of logarithms as deducible from the doctrine of ratios. It was in this way that the celebrated Kepler treated the subject; and he has been followed by Mercator, Halley, and Cotes, as well as by mathematicians of later times, as by Baron Maseres in his Trigonometry. The same mode was likewise adopted in the posthumous works of Dr Robert Simson. As, however, the doctrine of ratios is very abstract, and the mode of reasoning upon which it has been established is of a peculiar and subtile kind, we presume that the greater number of readers will think this view of the subject less simple and natural than the following, in which we mean to deduce the theory of logarithms, as well as the manner of computing them, from the properties of the exponents of powers.

The common scale of notation in arithmetic is so contrived as to express all numbers whatever by the powers of 10, which is the root of the scale, and the nine digits serving as co-efficients to these powers. Thus, if R denote 10, the root of the scale, so that R^2 will denote 100, and R^3 1000, and so on, the number 471,509 is otherwise expressed by $4R^5 + 7R^4 + 1R^3 + 5R^2 + 0R^1 + 9R^0$, which is

Nature of Logarithms.

equivalent to $4R^5 + 7R^4 + R^3 + 5R^2 + 9$. Again, the mixed number 371·243 is expressed by $3R^2 + 7R^1 + R^0 + \frac{2}{R} + \frac{4}{R^2} + \frac{3}{R^3}$, or by $3R^2 + 7R^1 + R^0 + 2R^{-1} + 4R^{-2} + 3R^{-3}$. As to vulgar fractions, by transforming them to decimals, they may be expressed in the same manner. Thus $\frac{3}{8} = {\cdot}375 = 3R^{-1} + 7R^{-2} + 5R^{-3}$. Also $\frac{2}{3} = {\cdot}666$, &c. $= 6R^{-1} + 6R^{-2} + 6R^{-3} +$ &c.

But instead of expressing all numbers by the sums of certain multiples of the successive powers of some particular number, we may also express them, if not accurately, at least as near as we please, by a single power, whole or fractional, of any positive number whatever, which may be either whole or fractional, but must not be unity.

Let us take, for example, 2 as the number, by the powers of which all others are to be expressed. Then it may be shown that the numbers 1, 2, 3, &c. are all expressible by the powers of 2, as follows.

$$\begin{array}{ll}
1 = 2^0 & 6 = 2^{2.58496} \text{ nearly} \\
2 = 2^1 & 7 = 2^{2.8073} \text{ nearly} \\
3 = 2^{1.58496} \text{ nearly} & 8 = 2^3 \\
4 = 2^2 & 9 = 2^{3.1699} \text{ nearly} \\
5 = 2^{2.3219} \text{ nearly} & 10 = 2^{3.3219} \text{ nearly}
\end{array}$$

and so on. And if instead of 2 we take the number 10, then we have

$$\begin{array}{ll}
1 = 10^0 & 6 = 10^{\cdot 77815} \\
2 = 10^{\cdot 30103} & 7 = 10^{\cdot 84510} \\
3 = 10^{\cdot 47712} & 8 = 10^{\cdot 90309} \\
4 = 10^{\cdot 60206} & 9 = 10^{\cdot 95424} \\
5 = 10^{\cdot 69897} & 10 = 10^1.
\end{array}$$

Hence we may conclude, that if r be put for some determinate number, and n for any indefinite positive number, whole or fractional, it is always possible to find another number N, such that r being raised to the power N, shall either be exactly equal to n, or as near it as we please; that is, we shall have $r^N = n$.

When numbers are expressed in this way by the powers of some given number r, *the exponent of that power of r which is equal to any assigned number is called the logarithm of that number.* Thus, if $r^N = n$ (n being put for any number), N is the logarithm of n.

The logarithms which are produced by giving to r some determinate value, constitute a *system* of logarithms; and the constant number r, from which the system is formed, is called the *base, radix,* or radical number of the system.

The properties of logarithms may readily be deduced from the above definition as follows: Let a and b be any two numbers, and A and B their logarithms; then r being supposed to denote the base or radical number of the system, we have $a = r^A$ and $b = r^B$: now if we take the product of a and b, we have $ab = r^A \times r^B = r^{A+B}$; but, according to the definition, A + B is the logarithm of ab (for it is the index of that power of r which is equal to ab), therefore *the sum of the logarithms of any two numbers a and b is the logarithm of their product ab.* Again, we have $\frac{a}{b} = \frac{r^A}{r^B} = r^{A-B}$, but here A — B, being the index of that power of r which is equal to $\frac{a}{b}$, is the logarithm of $\frac{a}{b}$; hence, *if one number a be divided by another b, the difference between their logarithms is the logarithm of the quotient* $\frac{a}{b}$.

Nature of Logarithms.

Let n express any number whatever, then raising both sides of the equation $a = r^A$ to the nth power, we have $a^n = (r^A)^n = r^{nA}$; but here nA is manifestly the logarithm of a^n; therefore, *the logarithm of a^n, any power of a number, is the product of the logarithm of the number by n, the index of the power. This must evidently be true, whether n be a whole number or a fraction, positive or negative.*

From these properties, it is easy to see in what manner a table exhibiting the logarithms of all numbers within certain limits may be applied to simplify calculations; for since the sum of the logarithms of any two numbers is the logarithm of their product, it follows, that as often as we have occasion to find the product of two or more numbers, we have only to add their logarithms taken from the table into one sum, and to look for the number whose logarithm is equal to that sum, and this number will be the product required. Also, because the difference between the logarithm of the dividend and that of the divisor is the logarithm of the quotient, whenever we have occasion to divide one number by another, we have only to subtract the logarithm of the divisor from that of the dividend, and opposite to that logarithm in the table, which is the remainder, we find the quotient.

As the logarithm of any power of a number is the product of the logarithm of the number by the index of the power; and, on the contrary, the logarithm of any root of a number is the quotient found by dividing the logarithm of the number by the index of the root; it follows that we may find any power or root of a number by multiplying the logarithm of the number by the index of the power, or dividing it by the index of the root, and taking that number in the table whose logarithm is the product or quotient for the power or root required.

If in the equation $a = r^A$ (where a is any number, A its logarithm, and r the base of the system) we suppose $a = 1$, then $r^A = 1$; but this equation can only be satisfied by $A = 0$. Hence it appears, *that in every system of logarithms, the logarithm of unity must be* 0. If, on the other hand, we assume $a = r$, then we have the equation $r = r^A$, which is immediately satisfied by putting $A = 1$; therefore, *the logarithm of the base, or radical number of every system, is necessarily unity.*

If we suppose r and a to be each a positive number greater than unity, then A will be a positive number; for if it be a negative we would have $a\left(= r^{-A} = \frac{1}{r^A}\right)$, a proper fraction, and at same time a number greater by hypothesis than unity, which is absurd. If, on the contrary, we suppose a a proper fraction, then A must necessarily be negative, otherwise r^A would be greater than unity, and $a\,(= r^A)$ also greater than unity, while by hypothesis it is a fraction less than unity, which is absurd. *Therefore, in every system, the base of which exceeds unity, the logarithm of a whole or mixed number is always positive, but the logarithm of a proper fraction is always negative.*

Because the logarithm of r is unity, that of r^n will be n; therefore, *the logarithm of any integral power of the radical number r will always be an integer.*

Let r and r' denote bases of two different systems; and let A be the logarithm of a number, a, taken according to the first of these, and A′ its logarithm according to the second. Then, because $a = r^A$, and $a = r'^{A'}$, it follows that $r^A = r'^{A'}$, and $r = r'^{\frac{A'}{A}}$. Let us now suppose that r'' is the base of a third system of logarithms, and R and R′, Nature of Logarithms.

the logarithms of r and r', taken according to this third system; then, because

$$r''^{\mathrm{R}} = r, \qquad r''^{\mathrm{R}'} = r';$$

we have $r''^{\mathrm{RR}'} = r^{\mathrm{R}'}$, $r''^{\mathrm{RR}'} = r'^{\mathrm{R}}$;

therefore $r^{\mathrm{R}'} = r'^{\mathrm{R}}$, and $r = r'^{\frac{\mathrm{R}}{\mathrm{R}'}}$; but we have already found $r = r'^{\frac{\mathrm{A}'}{\mathrm{A}}}$, therefore $r'^{\frac{\mathrm{A}'}{\mathrm{A}}} = r'^{\frac{\mathrm{R}}{\mathrm{R}'}}$, and consequently

$$\frac{\mathrm{A}'}{\mathrm{A}} = \frac{\mathrm{R}}{\mathrm{R}'}, \text{ and } \mathrm{A} : \mathrm{A}' (: : \mathrm{R}' : \mathrm{R}) : : \frac{1}{\mathrm{R}} = \frac{1}{\mathrm{R}'}.$$

Hence it appears, *that the logarithm of a number, taken according to one system, has to its logarithm, taken according to any other system, a constant ratio, which is the same as that of the reciprocals of the logarithms of the radical numbers of those systems.*

Let us next suppose that a and b are two numbers, and A and B their logarithms, taken according to the same system, and r the base of the system; then, because

$$r^{\mathrm{A}} = a, \qquad r^{\mathrm{B}} = b;$$

we have $r^{\mathrm{AB}} = a^{\mathrm{B}}$, $r^{\mathrm{AB}} = b^{\mathrm{A}}$;

therefore $a^{\mathrm{B}} = b^{\mathrm{A}}$, and $a = b^{\frac{\mathrm{A}}{\mathrm{B}}}$. Now as r is not found in this equation, the value of the fraction $\frac{\mathrm{A}}{\mathrm{B}}$ depends only on a and b; therefore, *the logarithms of any two given numbers have the same ratio to each other in every system.*

Having now explained the properties which belong to the logarithms of any system, we proceed to investigate general rules by which the number corresponding to any logarithm, and, on the contrary, the logarithm corresponding to any number, may be found the one from the other. And for this end let us denote any number whatever by y, and its logarithm by x, and put r as before for the base or radical number of the system; then, by the nature of logarithms,

$$y = r^x.$$

Put $r = 1 + a$, and let the expression $(1 + a)^x$ be expanded into a series by the binomial theorem; thus

$$y = 1 + x\,a + \frac{x\,(x-1)}{1\cdot 2}a^2 + \frac{x\,(x-1)\,(x-2)}{1\cdot 2\cdot 3} + \frac{x\,(x-1)\,(x-2)\,(x-3)}{1\cdot 2\cdot 3\cdot 4}a^4 + \&\text{c.}$$

Let this series, the terms of which are arranged according to the powers of a, be transformed into another, whose terms shall be arranged according to the powers of x; and to effect this we must find the actual products of the factors which constitute the powers of a, and arrange the terms anew, as follows:

$$\begin{aligned}
1 &= 1,\\
x\,a &= +\,a\,x,\\
\frac{x\,(x-1)}{1\cdot 2}\,a^2 &= -\frac{a^2}{2}x + \frac{a^2}{2}x^2,\\
\frac{x\,(x-1)\,(x-2)}{1\cdot 2\cdot 3}\,a^3 &= +\frac{a^3}{3}x - \frac{a^3}{2}x^3 + \frac{a^3}{6}x^3,\\
\frac{x(x-1)(x-2)(x-3)}{1\cdot 2\cdot 3\cdot 4}\,a^4 &= -\frac{a^4}{4}x + \frac{11\,a^4}{24}x^2 - \frac{a^4}{4} + x^3\frac{a^4}{24}x^4,\\
\&\text{c.} \qquad & \qquad \&\text{c.}
\end{aligned}$$

so that adding into one sum the quantities on each side of the sign $=$, and recollecting that the sum of those on the left-hand side is equal to y, we have

Construction of Logarithms.

$$y = r^x = \begin{cases}
1\\
+\,(a - \frac{a^2}{2} + \frac{a^3}{3} - \frac{a^4}{4} + \&\text{c.})\,x\\
+\,(\frac{a^2}{2} - \frac{a^3}{2} + \frac{11\,a^4}{24} - \&\text{c.})\,x^2\\
+\,(\frac{a^3}{6} - \frac{a^4}{4} + \&\text{c.})\,x^3\\
+\,(\frac{a^4}{24} - \&\text{c.})\,x^4\\
+\,\&\text{c.}
\end{cases}$$

$$\begin{aligned}
\text{Put } \mathrm{A} &= a - \frac{a^2}{2} + \frac{a^3}{3} - \frac{a^4}{4} + \&\text{c.}\\
\mathrm{A}' &= \frac{a^2}{2} - \frac{a^3}{2} + \frac{11\,a^4}{24} - \&\text{c.}\\
\mathrm{A}'' &= \frac{a^3}{6} - \frac{a^4}{4} + \&\text{c.}\\
\mathrm{A}''' &= \frac{a^4}{24} - \&\text{c.}\\
\&\text{c.}
\end{aligned}$$

then $r^x = 1 + \mathrm{A}x + \mathrm{A}'x^2 + \mathrm{A}''x^3 + \mathrm{A}'''x^4 + \&\text{c.}$

Next, to determine the law of connection of the quantities A, A′, A″, A‴, &c. since the last equation is to hold good whatever be the value of the variable quantity, a similar equation may be formed with the same co-efficients, and having $x + z$ for its variable (z being any indefinite quantity); thus we have also

$$r^{x+z} = 1 + \mathrm{A}(x+z) + \mathrm{A}'(x+z)^2 + \mathrm{A}''(x+z)^3 + \&\text{c.}$$

But $r^{x+z} = r^x \times r^z$, and since it has been shown that

$$r^x = 1 + \mathrm{A}x + \mathrm{A}'x^2 + \mathrm{A}''x^3 + \mathrm{A}'''x^4 + \&\text{c.}$$

for the same reason

$$r^z = 1 + \mathrm{A}z + \mathrm{A}'z^2 + \mathrm{A}''z^3 + \mathrm{A}'''z^4 + \&\text{c.}$$

therefore the series

$$1 + \mathrm{A}(x+z) + \mathrm{A}'(x+z)^2 + \mathrm{A}''(x+z)^3 + \mathrm{A}'''(x+z)^4 + \&\text{c.}$$

is equal to the product of the two series

$$1 + \mathrm{A}x + \mathrm{A}'x^2 + \mathrm{A}''x^3 + \mathrm{A}'''x^4 + \&\text{c.}$$
$$1 + \mathrm{A}z + \mathrm{A}'z^2 + \mathrm{A}''z^3 + \mathrm{A}'''z^4 + \&\text{c.}$$

That is, by the actual involution of the former and multiplication of the two latter,

$$\left.\begin{array}{l}
1 + \mathrm{A}x + \mathrm{A}'x^2 + \mathrm{A}''x^3 + \mathrm{A}'''x^4 + \&\text{c.}\\
+ \mathrm{A}z + 2\mathrm{A}'xz + 3\mathrm{A}''x^2z + 4\mathrm{A}'''x^3z + \&\text{c.}\\
\qquad + \mathrm{A}'z^2 + 3\mathrm{A}''xz^2 + 6\mathrm{A}'''x^2z^2 + \&\text{c.}\\
\qquad\qquad + \mathrm{A}''z^3 + 4\mathrm{A}'''xz^3 + \&\text{c.}\\
\qquad\qquad\qquad + \mathrm{A}'''z^4 + \&\text{c.}
\end{array}\right\} =$$

$$= \begin{cases}
1 + \mathrm{A}x + \mathrm{A}'x^2 + \mathrm{A}''x^3 + \mathrm{A}'''x^4 + \&\text{c.}\\
\quad + \mathrm{A}z + \mathrm{A}^2xz + \mathrm{A}\mathrm{A}'x^2z + \mathrm{A}\mathrm{A}''x^3z + \&\text{c.}\\
\qquad + \mathrm{A}'z^2 + \mathrm{A}\mathrm{A}'xz^2 + \mathrm{A}'\mathrm{A}'x^2z^2 + \&\text{c.}\\
\qquad\qquad + \mathrm{A}''z^3 + \mathrm{A}\mathrm{A}''xz^3 + \&\text{c.}\\
\qquad\qquad\qquad + \mathrm{A}'''z^4 + \&\text{c.}
\end{cases}$$

Now the quantities A, A′, A″, &c. being quite independent of x and z, the two sides of the equation can only be identical, upon the supposition that the co-efficients of like terms in each are equal; therefore, setting aside the first line of each side of the equation, because their terms are the same, and also the first term of the second line, for the same reason, let the co-efficients of the remaining terms be put equal to one another. Thus we have

$$\left.\begin{array}{r}
\mathrm{A}^2 = 2\mathrm{A}'\\
\mathrm{A}\mathrm{A}' = 3\mathrm{A}''\\
\mathrm{A}\mathrm{A}'' = 4\mathrm{A}'''\\
\&\text{c.}
\end{array}\right\} \text{ and hence we have } \left\{\begin{array}{l}
\mathrm{A}' = \frac{\mathrm{A}^2}{1\cdot 2}\\
\mathrm{A}'' = \frac{\mathrm{A}^3}{1\cdot 2\cdot 3}\\
\mathrm{A}''' = \frac{\mathrm{A}^4}{1\cdot 2\cdot 3\cdot 4}\\
\&\text{c.}
\end{array}\right.$$

Here the law of the co-efficients A, A′, A″, &c. is obvious, each being formed from the preceding by multiplying it by A, and dividing by the exponent of the power of A, which is thus formed. Let these values of A′, A″, &c. be now substituted in the equation

$$y=r^x=1+Ax+A'x^2+A''x^3+\&c.$$

and it becomes

$$y=1+Ax+\frac{A^2}{1\cdot 2}x^2+\frac{A^3}{1\cdot 2\cdot 3}x^3+\frac{A^4}{1\cdot 2\cdot 3\cdot 4}x^4+\&c.$$

Thus we have obtained a general formula expressing a number in terms of its logarithm and the base of the system, for we must recollect that since $a=r-1$, the quantity A, which is equal to

$$a-\frac{a^2}{2}+\frac{a^3}{3}-\frac{a^4}{4}+\frac{a^5}{5}-\&c.$$

is otherwise expressed by

$$r-1-\frac{(r-1)^2}{2}+\frac{(r-1)^3}{3}-\frac{(r-1)^4}{4}+\frac{(r-1)^5}{5}-\&c.$$

where r denotes the base of the system.

If in the formula

$$r^x=1+Ax+\frac{A^2}{1\cdot 2}x^2+\frac{A^3}{1\cdot 2\cdot 3}x^3+\frac{A^4}{1\cdot 2\cdot 3\cdot 4}x^4+\&c.$$

we suppose $x=1$, it becomes

$$r=1+A+\frac{A^2}{1\cdot 2}+\frac{A^3}{1\cdot 2\cdot 3}+\frac{A^4}{1\cdot 2\cdot 3\cdot 4}+\&c.$$

an equation which contains r only; but as r has been all along supposed an indeterminate quantity, this equation must be identical, that is, if, instead of A, its value, as expressed above in terms of r, were substituted, the equation would become $r=r$.

Again, let us suppose that $\frac{1}{A}$ is substituted instead of x in the general formula; thus it becomes

$$r^{\frac{1}{A}}=1+1+\frac{1}{1\cdot 2}+\frac{1}{1\cdot 2\cdot 3}+\frac{1}{1\cdot 2\cdot 3\cdot 4}+\&c.$$

Thus the quantity $r^{\frac{1}{A}}$, whatever be the value of r, is evidently equal to a constant number, which, as appears from the last equation, is equal to the value of r when $A=1$. By adding together a sufficient number of terms of the last series, we find it nearly equal to

2·7182818284590452353602874.

If this be denoted by e, we have $r^{\frac{1}{A}}=e$, and $r=e^A$; hence, if the number e be considered as the base of a logarithmic system, the quantity A, namely,

$$r-1-\frac{(r-1)^2}{2}+\frac{(r-1)^3}{3}-\frac{(r-1)^4}{4}+\frac{(r-1)^5}{5}-\&c.$$

is the logarithm of r to the base e. But as r is not restricted here to any particular value, we may substitute y instead of it, keeping in mind that y denotes any number whatever, and x its logarithm; thus we have x the logarithm of y, expressed by the series

$$y-1-\frac{(y-1)^2}{2}+\frac{(y-1)^3}{3}-\frac{(y-1)^4}{4}+\frac{(y-1)^5}{5}-\&c.$$

supposing that the base of the system is the number we have expressed above by e.

We have now found a general formula for the logarithm of any number y, taken according to a particular system, namely, that which has the number e for its base. But it is easy from hence to find a formula, which shall apply to any system whatever. For it has been shown that the logarithms of the same number, taken according to two different systems, are to each other as the reciprocals of the logarithms of the bases of the systems, these last logarithms being taken according to any system whatever, that is,

Construction of Logarithms.

$$\log. y \text{ to base } e : \log. y \text{ to base } r :: \frac{1}{\log. e} : \frac{1}{\log. r};$$

hence we find

$$\log. y \text{ to base } r=\frac{\log. e}{\log. r}\times\log. y \text{ to base } e.$$

Let the value already found for the logarithm of y to base e be substituted in this equation, and it becomes

$$\log. y=x=\frac{\log. e}{\log. r}\left\{y-1-\frac{(y-1)^2}{2}+\frac{(y-1)^3}{3}-\frac{(y-1)^4}{4}+\&c.\right\}$$

which is a general formula for the logarithm of *any number whatever*, to the base r. And it is to be recollected that in the fraction $\frac{\log. e}{\log. r}$, which is a common multiplier to the series, the logarithms are to be taken according to the same base, which however may be any number whatever.

If in the above formula we suppose $r=e$, the multiplier $\frac{\log. e}{\log. r}$ will be unity, and the formula will become simply

$$\log. y=y-1-\frac{(y-1)^2}{2}+\frac{(y-1)^3}{3}-\frac{(y-1)^4}{4}+\&c.$$

as we have already remarked. Now this is the system which was adopted by Lord Napier; and although the logarithms which were computed according to this system, or upon the supposition that the radical number is 2·7182818, &c. have been called *hyperbolic logarithms*, because they happen to be proportional to certain hyperbolic spaces, yet, as the logarithms of every system have the same property, it is more proper to call them *Napierian logarithms*.

As the constant multiplier $\frac{\log. e}{\log. r}$, which occurs in the general formula for the logarithm of any number, is the only part of the formula which depends for its value upon the base of the system, it has been called by writers on logarithms the *modulus* of the system. If we suppose the logarithms taken to the base e, then the numerator, viz. log. e, will be unity, and the denominator will be the Napierian logarithm of r. If however we suppose the logarithms taken to the base r, then the numerator will be log. e to base r; and the denominator will be unity, so that the *modulus* of any system whose base is r, is *the reciprocal of the Napierian logarithm of that base;* or it is *the logarithm of the number e* (the base of the Napierian system) *to the base r.*

In the Napierian system, the *modulus* is unity, and hence the logarithms of this system are more easily computed than those of any other. It was, however, soon found that a system whose base should be the same as the root of the scale of the arithmetical notation, viz. the number 10, would be the most convenient of any in practice; and accordingly such a system was actually constructed by Mr Briggs. This is the only one now in common use, and is called *Briggs's system*, also *the common system* of logarithms. The *modulus* of this system therefore is the reciprocal of the Napierian logarithm of 10, viz. ·43429448, which is the common logarithm of $e=2·7182818$, &c. the base of the Napierian system. We shall in future denote this *modulus* by M; so that the formula expressing the common logarithm of any number y will be

$$\log. y=M\left\{1-y-\frac{(1-y)^2}{2}+\frac{(1-y)^3}{3}-\frac{(1-y)^4}{4}+\&c.\right\}$$

If the number y, whose logarithm is required, be very near to unity, so that $1-y$ is a small quantity, then the logarithm may be found from this formula with great ease, because the series will converge very rapidly. If, however, $1-y$ be greater than unity, the series, instead of converging, will diverge, so as to be, in its present form, of no use.

It may, however, be transformed into another, which shall converge in every case, by substituting in it $\sqrt[n]{y}$ instead of y, and observing that $\log.\ (\sqrt[n]{y}) = \frac{\log.\ y}{n}$; it thus becomes

$$\log. y = n\mathrm{M}\{\sqrt[n]{y}-1-\tfrac{1}{2}(\sqrt[n]{y}-1)^2+\tfrac{1}{3}(\sqrt[n]{y}-1)^3-\&c.\}$$

where n may denote any number, positive or negative. But whatever be the number y, we can always take n, such, that $\sqrt[n]{y}$ shall be as near to 1 as we please; therefore, by this last formula, we can always find the logarithm of y to any degree of accuracy.

If n be taken negative, then $\sqrt[n]{y} = \frac{1}{\sqrt[n]{y}}$, and the series for $\log.\ y$ becomes, by changing the signs,

$$\log. y = n\mathrm{M}\left\{1-\frac{1}{\sqrt[n]{y}}+\tfrac{1}{2}\left(1-\frac{1}{\sqrt[n]{y}}\right)^2+\tfrac{1}{3}\left(1-\frac{1}{\sqrt[n]{y}}\right)^3 + \&c.\right\}$$

where all the terms are positive. Thus we have it in our power to express the value of y, either by a series which shall have its terms all positive, or by one which shall have its terms alternately positive and negative: for it is evident that if y be greater than unity, $\sqrt[n]{y}$ will also be greater than unity, and *vice versa;* but the differences will be so much the smaller as n the exponent of the root is greater; therefore $\sqrt[n]{y}-1$ will be positive in the first case, and negative in the second.

Because Nap. log. $10 = \frac{1}{\mathrm{M}}$, we have by the two last formulas

$$\frac{1}{\mathrm{M}} = n\{\sqrt[n]{10}-1-\tfrac{1}{2}(\sqrt[n]{10}-1)^2+\tfrac{1}{3}(\sqrt[n]{10}-1)^3 - \&c.\}$$

also

$$\frac{1}{\mathrm{M}} = n\left\{1-\frac{1}{\sqrt[n]{10}}+\tfrac{1}{2}\left(1-\frac{1}{\sqrt[n]{10}}\right)^2+\tfrac{1}{3}\left(1-\frac{1}{\sqrt[n]{10}}\right)^3 + \&c.\right\}$$

It is evident, that by giving to $\sqrt[n]{y}$ such a value that $\sqrt[n]{y}-1$ is a fraction less than unity, we render both the series for the value of $\log.\ y$ converging; for then the expression $1-\frac{1}{\sqrt[n]{y}}$ will also be less than unity, seeing it is equal $\frac{\sqrt[n]{y}-1}{\sqrt[n]{y}}$. Therefore, in the first series, the second and third terms (taken together as one term) constitute a negative quantity; and as the same is also true of the fourth and fifth, and so on, the amount of all the terms after the first is a negative quantity, or one which is to be subtracted from the first, to obtain the value of log y. Hence

$$\log. y \angle n\mathrm{M}(\sqrt[n]{y}-1).$$

And since, on the contrary, the terms of the second series are all positive, the amount of all the terms after the first is a positive quantity, or one which must be added to the first to give the value of $\log.\ y$; so that

$$\log. y \mathrel{7} n\mathrm{M}\left(1-\frac{1}{\sqrt[n]{y}}\right).$$

Thus we have two limits to the value of the logarithm of y, which, by taking the number n sufficiently great, may come as near to each other as we please.

In like manner we find two limits to the value of the reciprocal to the modulus, viz.

$$\frac{1}{\mathrm{M}} \angle n(\sqrt[n]{10}-1),\ \frac{1}{\mathrm{M}} \mathrel{7} n\left(1-\frac{1}{\sqrt[n]{10}}\right).$$

It is evident that the difference between the two limits of $\log.\ y$, is

$$n\mathrm{M}\left\{(\sqrt[n]{y}-1)-\left(1-\frac{1}{\sqrt[n]{y}}\right)\right\},$$

therefore, if we take either the one or the other of the two preceding expressions for log y, the error in excess or defect is necessarily less than this quantity.

By these formulæ we may depend upon having the logarithm of any number true to m figures, if we give to n such a value that the root $\sqrt[n]{y}$ shall have m ciphers between the decimal point and the first significant figure on the right. So that in general, as the error is the smaller as n the exponent of the root is greater, it may be neglected when n is taken indefinitely great; and this being the case, we may conclude that either of these expressions,

$$n\mathrm{M}(\sqrt[n]{y}-1),\ n\mathrm{M}\left(1-\frac{1}{\sqrt[n]{y}}\right)$$

is the accurate value of $\log.\ y$.

The best manner of applying the preceding formula is to take some power of the number 2 for n; for by doing so, the root $\sqrt[n]{y}$ may be found by a repetition of extractions of the square root only. It was in this way that Briggs calculated the first logarithms; and he remarked, that if in performing the successive extractions of the square root, he at last obtained twice as many decimal places as there were ciphers after the decimal point, the integer before it being unity, then the decimal part of this root was exactly the half of that which went before; so that the decimal parts of the two roots were to each other in the same proportion as their logarithms: now this is an evident consequence of the preceding formula.

To give an example of the application of the formula, let it be required to find the numerical value of M, the modulus of the common system of logarithms, which, as it is the reciprocal of the Napierian logarithm of 10, is

$$\frac{1}{n} \times \frac{1}{\sqrt[n]{10}-1} \text{ nearly,}$$

when n is some very great number. Let us suppose $n = 2^{60} = 8^{20}$; then, dividing unity by 8, and this result again by 8, and so on, we shall, after 20 divisions, have $\frac{1}{n}$, or $\frac{1}{8^{20}}$, equal to

0·00000 00000 00000 00086 73617 37988 40354.

Also, by extracting the square root of 10, and the square root of this result, and so on, after performing 60 extractions we shall find $\sqrt[n]{10}$ equal to

1·00000 00000 00000 00199 71742 08125 50527 03251.

Therefore, $\frac{1}{n} \times \frac{1}{\sqrt[n]{10}-1}$, or M is equal to

$$\frac{86736173798840354}{199717420812550527} = 0{\cdot}4342944819.$$

As a second example, let it be required to find by the same formula the logarithm of 3, which is nearly

$$n\mathrm{M}(\sqrt[n]{3}-1) = \frac{n(\sqrt[n]{3}-1)}{n(\sqrt[n]{10}-1)} = \frac{\sqrt[n]{3}-1}{\sqrt[n]{10}-1},$$

n being as before a very great number. Let us suppose also in this case that $n = 2^{60}$; then after 60 extractions of the square root we have $\sqrt[n]{3}$ equal to

1·00000 00000 00000 0095 28942 64074 58932.

Construction of Logarithms.

Therefore, taking the value of ${}^{n}\sqrt{10}$ as found in last example, we have

$$\log. 3 = \frac{{}^{n}\sqrt{3}-1}{\sqrt{10}-1} = \frac{95289426407458932}{199717420812550527}$$
$$= \cdot 477121254719662.$$

This method of computing logarithms is evidently attended with great labour, on account of the number of extractions of roots which it requires to obtain a result true to a moderate number of places of figures. But the two series which we have given serve to simplify and complete it. For, whatever be the number y, it is only necessary to proceed with the extractions of the square root, till we have obtained for ${}^{n}\sqrt{y}$ a value which is unity followed by a decimal fraction; and then ${}^{n}\sqrt{y}-1$ being a fraction, its powers will also be fractions so much the smaller as their exponents are greater; thus a certain number of terms of the series will express the logarithm to as many decimal places as may be required.

There are yet other artifices by which the series $\log. y = \mathrm{M}\{y-1-\frac{1}{2}(y-1)^2+\frac{1}{3}(y-1)^3-\frac{1}{4}(y-1)^4+\&c.\}$ may be transformed into others which shall always converge, and in particular the following. Let $1+u$ be substituted in the series for y; then it becomes

$$\log. (1+u) = \mathrm{M}\left(u-\frac{u^2}{2}+\frac{u^3}{3}-\frac{u^4}{4}+\frac{u^5}{5}-\&c.\right)$$

In like manner, if $1-u$ be substituted for y, we have

$$\log. (1-u) = \mathrm{M}\left(-u-\frac{u^2}{2}-\frac{u^3}{3}-\frac{u^4}{4}-\frac{u^5}{5}-\&c.\right)$$

Let the latter equation be subtracted from the former; and since $\log. (1+u)-\log. (1-u)$, is equal to $\log. \frac{1+u}{1-u}$; we shall have

$$\log. \frac{1+u}{1-u} = 2\mathrm{M}\left\{u+\frac{u^3}{3}+\frac{u^5}{5}+\frac{u^7}{7}+\&c.\right\},$$

which series, by substituting z for $\frac{1+u}{1-u}$, and consequently $\frac{z-1}{z+1}$ for u, will be otherwise expressed thus,

$$\log. z = 2\mathrm{M}\left\{\frac{z-1}{z+1}+\tfrac{1}{3}\left(\frac{z-1}{z+1}\right)^3+\tfrac{1}{5}\left(\frac{z-1}{z+1}\right)^5+\&c.\right\};$$

which is not only simple, but has also the property of converging in every case.

As an example of the utility of this formula, we shall employ it to compute the Napierian logarithm of 2, which will be

$$2\left(\frac{1}{3}+\frac{1}{3\cdot 3^3}+\frac{1}{5\cdot 3^5}+\frac{1}{7\cdot 3^7}+\frac{1}{9\cdot 3^9}+\&c.\right)$$
$$= \mathrm{A}+\tfrac{1}{3}\mathrm{B}+\tfrac{1}{5}\mathrm{C}+\tfrac{1}{7}\mathrm{D}+\tfrac{1}{9}\mathrm{E}+\&c.$$

where A is put for $\frac{2}{3}$, B for $\frac{2}{3^3}=\frac{\mathrm{A}}{9}$, C for $\frac{2}{3^5}=\frac{\mathrm{B}}{9}$, D for $\frac{2}{3^7}=\frac{\mathrm{C}}{9}$, &c. The calculation will be as follows:

$$\begin{aligned}
\mathrm{A} &= \phantom{\tfrac{1}{9}\mathrm{A} =}\ \cdot 666666666666\\
\mathrm{B} &= \tfrac{1}{9}\mathrm{A} = \cdot 074074074074\\
\mathrm{C} &= \tfrac{1}{9}\mathrm{B} = \cdot 008230452674\\
\mathrm{D} &= \tfrac{1}{9}\mathrm{C} = \cdot 000914494742\\
\mathrm{E} &= \tfrac{1}{9}\mathrm{D} = \cdot 000101610527\\
\mathrm{F} &= \tfrac{1}{9}\mathrm{E} = \cdot 000011290059\\
\mathrm{G} &= \tfrac{1}{9}\mathrm{F} = \cdot 000001254451\\
\mathrm{H} &= \tfrac{1}{9}\mathrm{G} = \cdot 000000139383\\
\mathrm{I} &= \tfrac{1}{9}\mathrm{H} = \cdot 000000015487\\
\mathrm{K} &= \tfrac{1}{9}\mathrm{I} = \cdot 000000001721\\
\mathrm{L} &= \tfrac{1}{9}\mathrm{K} = \cdot 000000000191\\
\mathrm{M} &= \tfrac{1}{9}\mathrm{L} = \cdot 000000000021
\end{aligned}$$

$$\begin{aligned}
\mathrm{A} &= \cdot 666666666666\\
\tfrac{1}{3}\mathrm{B} &= \cdot 024691358025\\
\tfrac{1}{5}\mathrm{C} &= \cdot 001646090535\\
\tfrac{1}{7}\mathrm{D} &= \cdot 000130642106\\
\tfrac{1}{9}\mathrm{E} &= \cdot 000011290056\\
\tfrac{1}{11}\mathrm{F} &= \cdot 000001026369\\
\tfrac{1}{13}\mathrm{G} &= \cdot 000000096496\\
\tfrac{1}{15}\mathrm{H} &= \cdot 000000009292\\
\tfrac{1}{17}\mathrm{K} &= \cdot 000000000911\\
\tfrac{1}{19}\mathrm{L} &= \cdot 000000000091\\
\tfrac{1}{21}\mathrm{M} &= \cdot 000000000001\\
\hline
\text{Nap. log. } 2 &= \cdot 693147180551
\end{aligned}$$

Thus, by a very easy calculation, we have obtained the Napierian logarithm of 2 true to the first ten places of figures; the accurate value, as far as the 12th place, being 0·693147180560.

If this very simple process, by which we have found the logarithm of 2 (the whole of which is here actually put down), be compared with the laborious calculations which must have been performed to have found the same logarithm by the method explained in the beginning of this section, the great superiority of this method to the other, and even to the second method, by which we found the value of M, and the logarithm of 3, must be very apparent.

In the same manner as we have found the logarithm of 2, we may find those of 3, 5, &c. In computing the logarithm of 3, the series would converge by the powers of the fraction $\frac{3-1}{3+1}=\frac{1}{2}$, and in computing the logarithm of 5 it would converge by the powers of $\frac{5-1}{5+1}=\frac{2}{3}$; but in each of these cases the series would converge slower, and of course the labour would be greater than in computing the logarithm of 2. And if the number whose logarithm was required was still more considerable; as, for example, 199, the series would converge so slow as to be useless.

We may however avoid this inconvenience by again transforming this last formula into another which shall express the logarithm of any number by means of a series, and a logarithm supposed to be previously known. To effect this new transformation, let $\frac{1+u}{1-u}=1+\frac{z}{n}$, and consequently $u=\frac{z}{2n+z}$, these values being substituted in the formula, $\log. \frac{1+u}{1-u}=2\mathrm{M}\left(u+\frac{u^3}{3}+\frac{u^5}{5}+\frac{u^7}{7}+\&c.\right)$ we have $\log. \left(1+\frac{z}{n}\right)$ equal to

$$2\mathrm{M}\left\{\frac{z}{2n+z}+\tfrac{1}{3}\left(\frac{z}{2n+z}\right)^3+\tfrac{1}{5}\left(\frac{z}{2n+z}\right)^5+\&c.\right\}$$

but $\log. \left(1+\frac{z}{n}\right)=\log. \frac{n+z}{n}=\log. (n+z)-\log. n$, therefore, $\log. (n+z)=\log. n+$

$$2\mathrm{M}\left\{\frac{z}{2n+z}+\tfrac{1}{3}\left(\frac{z}{2n+z}\right)^3+\tfrac{1}{5}\left(\frac{z}{2n+z}\right)^5+\&c.\right\}$$

By the assistance of this formula, and the known properties of logarithms, we may proceed calculating the logarithm of one number from that of another as follows.

To find the Napierian logarithm of 3 from that of 2, already found. We have here $n=2$, $z=1$, and $\frac{z}{2n+z}=\frac{1}{5}$. Therefore the logarithm of 3 is

$$\log. 2+2\left(\frac{1}{5}+\frac{1}{3\cdot 5^3}+\frac{1}{5\cdot 5^5}+\frac{1}{7\cdot 5^7}+\&c.\right)$$
$$= \log. 2+\mathrm{A}+\tfrac{1}{3}\mathrm{B}+\tfrac{1}{5}\mathrm{C}+\tfrac{1}{7}\mathrm{D}+\tfrac{1}{9}\mathrm{E}+\&c.$$

Construction of Logarithms.

where A is put for $\frac{2}{5}$, B for $\frac{A}{25}$, C for $\frac{B}{25}$, and so on.

The calculation may stand thus:

$$\begin{array}{rl}
A & = \cdot 400000000000 \\
B = \frac{1}{25}\,A & = \cdot 016000000000 \\
C = \frac{1}{25}\,B & = \cdot 000640000000 \\
D = \frac{1}{25}\,C & = \cdot 000025600000 \\
E = \frac{1}{25}\,D & = \cdot 000001024000 \\
F = \frac{1}{25}\,E & = \cdot 000000040960 \\
G = \frac{1}{25}\,F & = \cdot 000000001638 \\
H = \frac{1}{25}\,G & = \cdot 000000000066
\end{array}$$

$$\begin{array}{rl}
A & = \cdot 400000000000 \\
\frac{1}{3}\,B & = \cdot 005333333333 \\
\frac{1}{5}\,C & = \cdot 000128000000 \\
\frac{1}{7}\,D & = \cdot 000003657143 \\
\frac{1}{9}\,E & = \cdot 000000113778 \\
\frac{1}{11}\,F & = \cdot 000000003724 \\
\frac{1}{13}\,G & = \cdot 000000000126 \\
\frac{1}{15}\,H & = \cdot 000000000004 \\
\hline
 & \ \cdot 405465108108 \\
\text{Nap. log. } 2 & = \cdot 693147180551 \\
\hline
\text{Nap. log. } 3 & = 1\cdot 098612288659
\end{array}$$

This logarithm is true to 10 decimal places, the accurate value to 12 figures being 1·098612288668, which would have been our result had the correct value of log. 2, viz. ·693147180560 been employed.

The Napierian logarithm of 4 is immediately had from that of 2 by considering that as $4 = 2^2$, therefore log. 4 = log. 2 + log. 2.

$$\begin{array}{rl}
\text{Nap. log. } 2 & = \cdot 693147180551 \\
 & 2 \\
\hline
\text{Nap. log. } 4 & = 1\cdot 386294361102
\end{array}$$

This is also true to 10 places besides the integer.

To find the Napierian logarithm of 5, from that of 4; we have $n = 4$, $z = 1$, and $\frac{z}{2n+1} = \frac{1}{9}$, therefore the logarithm of 5 is expressed by

$$\text{log. } 4 + 2\left(\frac{1}{9} + \frac{1}{3 \cdot 9^3} + \frac{1}{5 \cdot 9^5} + \frac{1}{7 \cdot 9^7} + \text{\&c.}\right)$$

$$\text{log. } 4 + A + \tfrac{1}{3}B + \tfrac{1}{5}C + \tfrac{1}{7}D + \text{\&c.}$$

where $A = \frac{2}{9}$, $B = \frac{1}{81}A$, $C = \frac{1}{81}B$, &c.

The calculation.

$$\begin{array}{rl}
A & = \cdot 222222222222 \\
B = \frac{1}{81}\,A & = \cdot 002743484225 \\
C = \frac{1}{81}\,B & = \cdot 000033870176 \\
D = \frac{1}{81}\,C & = \cdot 000000418150 \\
E = \frac{1}{81}\,D & = \cdot 000000005162 \\
F = \frac{1}{81}\,E & = \cdot 000000000064
\end{array}$$

$$\begin{array}{rl}
A & = \cdot 222222222222 \\
\frac{1}{3}\,B & = \cdot 000914494742 \\
\frac{1}{5}\,C & = \cdot 000006774035 \\
\frac{1}{7}\,D & = \cdot 000000059736 \\
\frac{1}{9}\,E & = \cdot 000000000574 \\
\frac{1}{11}\,F & = \cdot 000000000006 \\
\hline
 & \ \cdot 223143551315 \\
\text{Nap. log. } 4 & = 1\cdot 386294361102 \\
\hline
\text{Nap. log. } 5 & = 1\cdot 609437912417
\end{array}$$

This result is also correct to the first ten places.

The logarithm of 6 is found from those of 2 and 3, because 6 = 2 × 3, therefore log. 6 = log. 2 + log. 3.

Construction of Logarithms.

$$\begin{array}{rl}
\text{Nap. log. } 2 & = 0\cdot 693147180551 \\
\text{Nap. log. } 3 & = 1\cdot 098612288659 \\
\hline
\text{Nap. log. } 6 & = 1\cdot 761759469210
\end{array}$$

This result is correct as far as the tenth decimal place.

We might find the logarithm of 7 from that of 6, that is, from the logarithms of 3 and 2, in the same manner as we have found the logarithms of 5 and 3; but it may be more readily found from the logarithms of 2 and 5 thus. Because $\frac{2 \times 5^2}{7^2} = \frac{50}{49}$, therefore log. 2 + 2 log. 5 — 2 log. 7 = log. $\frac{50}{49}$, and consequently

$$\text{log. } 7 = \tfrac{1}{2}\text{log. } 2 + \text{log. } 5 - \tfrac{1}{2}\text{log. } \frac{50}{49}.$$

Now the logarithm of $\frac{50}{49}$ may be readily obtained from

$$\text{log. } z = 2M\left\{\frac{z-1}{z+1} + \tfrac{1}{3}\left(\frac{z-1}{z+1}\right)^3 + \tfrac{1}{5}\left(\frac{z-1}{z+1}\right)^5 + \text{\&c.}\right\}$$

For, substituting $\frac{50}{49}$ for z, the formula gives

$$\begin{aligned}
\text{Nap. log. } \frac{50}{49} &= 2\left(\frac{1}{99} + \frac{1}{3 \cdot 99^3} + \frac{1}{5 \cdot 99^5} + \text{\&c.}\right) \\
&= A + \tfrac{1}{3}B + \tfrac{1}{5}C + \text{\&c.}
\end{aligned}$$

where $A = \frac{2}{9 \cdot 11}$, $B = \frac{A}{9^2 \cdot 11^2}$, $C = \frac{B}{9^2 \cdot 11^2}$, &c. This series converges with great rapidity, and a few of its terms will be sufficient to give the logarithm of 7, as appears from the following operation.

$$\begin{array}{rl}
A & = \cdot 020202020202 \\
B = \frac{1}{9^2 \cdot 11^2}\,A & = \cdot 000002061220 \\
C = \frac{1}{9^2 \cdot 11^2}\,B & = \cdot 000000000210
\end{array}$$

$$\begin{array}{rl}
A & = \cdot 020202020202 \\
\frac{1}{3}B & = \cdot 000000687073 \\
\frac{1}{5}C & = \cdot 000000000042 \\
\hline
\text{Nap. log. } \frac{50}{49} & = \cdot 020202707317
\end{array}$$

$$\begin{array}{rl}
\frac{1}{2}\text{log. } 2 & = 0\cdot 346573590275 \\
\text{log. } 5 & = 1\cdot 609437912417 \\
\hline
 & \ 1\cdot 956011502692 \\
\frac{1}{2}\text{log. } \frac{50}{49} & = 0\cdot 010101353658 \\
\hline
\text{Nap. log. } 7 & = 1\cdot 945910149034
\end{array}$$

This logarithm, like those we found before, is correct in the first ten decimal places.

The logarithms of 8, 9, and 10 are immediately obtained from those of 2, 3, and 5, as follows:

$$\begin{array}{rl}
\text{Nap. log. } 2 & = 0\cdot 693147180551 \\
 & 3 \\
\hline
\text{Nap. log. } 8 & = 2\cdot 079441541653
\end{array}$$

$$\begin{array}{rl}
\text{Nap. log. } 3 & = 1\cdot 098612288659 \\
 & 2 \\
\hline
\text{Nap. log. } 9 & = 2\cdot 197224577318
\end{array}$$

$$\begin{array}{rl}
\text{Nap. log. } 2 & = 0\cdot 693147180551 \\
\text{Nap. log. } 5 & = 1\cdot 609437912417 \\
\hline
\text{Nap. log. } 10 & = 2\cdot 302585092968
\end{array}$$

Thus by a few calculations we have found the Napierian logarithms of the first ten numbers, each true to ten decimal places; and since the Napierian logarithm of 10 is now known, the *modulus* of the common system, which is the reciprocal of that logarithm, will also be known, and will be

$$\frac{}{2\cdot302585092968} = \cdot4342944819.$$

The common logarithms of the first ten numbers may now be found from the Napierian logarithms by multiplying each of the latter by the *modulus*, or dividing by its reciprocal, that is, by the Napierian logarithm of 10. And as the *modulus* of the common system is so important an element in the theory of logarithms, we shall give its value, together with that of its reciprocal, as far as the 30th decimal place.

$$\text{M} = \cdot434294481903251827651128918916$$

$$\frac{1}{\text{M}} = 2\cdot302585092994045684017991454684$$

The formulæ already given are sufficient for finding the logarithms of all numbers whatever throughout the table; but there are yet others which may often be applied with great advantage, and we shall now investigate some of these.

Because

$$\text{log. } z = 2\text{M}\left\{\frac{z-1}{z+1} + \tfrac{1}{3}\left(\frac{z-1}{z+1}\right)^3 + \tfrac{1}{5}\left(\frac{z-1}{z+1}\right) \text{ \&c.}\right\}$$

If we now suppose

$$z = \frac{n^2}{n^2-1} = \frac{n^2}{(n-1)(n+1)},$$

so that $\frac{z-1}{z+1} = \frac{1}{2n^2-1}$, then the formula becomes

$$\text{log. } \frac{n^2}{(n-1)(n+1)} = 2\text{M}\left\{\frac{1}{2n^2-1} + \tfrac{1}{3}\left(\frac{1}{2n^2-1}\right)^3 + \tfrac{1}{5}\left(\frac{1}{2n^2-1}\right)^5 + \text{ \&c.}\right\}$$

But $\text{log. } \frac{n^2}{(n-1)(n+1)} = 2 \text{ log. } n - \text{log. } (n-1) - \text{log. } (n+1)$, therefore, putting N for the series

$$2\text{M}\left\{\frac{1}{2n^2-1} + \tfrac{1}{3}\left(\frac{1}{2n^2-1}\right)^3 + \tfrac{1}{5}\left(\frac{1}{2n^2-1}\right)^5 + \text{ \&c.}\right\}$$

we have this formula,

$$2 \text{ log. } n - \text{log. } (n-1) - \text{log. } (n+1) = \text{N};$$

and hence, as often as we have the logarithms of any two of three numbers whose common difference is unity, the logarithm of the remaining number may be found. Example: Given log. 9 = 0·95424250943, log. 10 = 1; to find the common logarithm of 11.

Here we have $n = 10$, so that the formula gives in this case 2 log. 10 — log. 9 — log. 11 = N, and hence we have

$$\text{log. } 11 = 2 \text{ log. } 10 - \text{log. } 9 - \text{N},$$

$$\text{where N} = \frac{2\text{M}}{199} + \frac{2\text{M}}{3\cdot199^3} + \text{ \&c.}$$

M being ·43429448190.

Calculation of N.

$$\text{A} = \frac{2\text{M}}{199} = \cdot00436476866$$

$$\text{B} = \frac{\text{A}}{3\cdot199^2} = \cdot00000003674$$

$$\begin{aligned} \text{N} &= 0\cdot00436480540 \\ \text{log. } 9 &= 0\cdot95424250943 \\ \hline \text{log. } 9 + \text{N} &= 0\cdot95860731483 \\ 2 \text{ log. } 10 &= 2\cdot00000000000 \\ \hline \text{log. } 11 &= 1\cdot04139268517 \end{aligned}$$

Construction of Logarithms.

Here the series expressed by N converges very fast, so that two of its terms are sufficient to give the logarithm true to 10 places of decimals. But the logarithm of 11 may be expressed by the logarithms of smaller numbers, and a series which converges still more rapidly, by the following artifice, which will apply also to some other numbers. Because the numbers 98, 99, and 100 are the products of numbers, the greatest of which is 11, for $98 = 2 \times 7^2$, $99 = 9 \times 11$, and $100 = 10 \times 10$, it follows that if we have an equation composed of terms which are the logarithms of these three numbers, it may be resolved into another, the terms of which shall be the logarithms of the number 11 and other smaller numbers. Now by the preceding formula, if we put 99 for n, we have

$$2 \text{ log. } 99 - \text{log. } 98 - \text{log. } 100 = \text{N},$$

that is, substituting log. 9 + log. 11 for log. 99, log. 2 + 2 log. 7 for log. 98, and 2 log. 10 for log. 100,

$$2 \text{ log. } 9 + 2 \text{ log. } 11 - \text{log. } 2 - 2 \text{ log. } 7 - 2 \text{ log. } 10 = \text{N},$$

and hence by transposition, &c.

$$\text{log. } 11 = \tfrac{1}{2}\text{N} + \tfrac{1}{2}\text{log. } 2 + \text{log. } 7 - \text{log. } 9 + \text{log. } 10;$$

and in this equation

$$\text{N} = \frac{2\text{M}}{19601} + \tfrac{1}{3}\,\frac{2\text{M}}{19601^3} + \text{ \&c.}$$

The first term alone of this series is sufficient to give the logarithm of 11 true to 14 places.

Another formula, by which the logarithm of a number is expressed by the logarithms of other numbers and a series, may be found as follows.

Resuming the formula

$$\text{log. } z = 2\text{M}\left\{\frac{z-1}{z+1} + \tfrac{1}{3}\left(\frac{z-1}{z+1}\right)^3 + \tfrac{1}{5}\left(\frac{z-1}{z+1}\right)^5 + \text{ \&c.}\right\}$$

$$\text{put } z = \frac{(n-1)^2\,(n+2)}{(n-2)\,(n+1)^2} = \frac{n^3-3\,n+2}{n^3-3\,n-2},$$

$$\text{then } \frac{z-1}{z+1} = \frac{2}{n^3-3n}.$$

Let these values of z, and $\frac{z-1}{z+1}$, be substituted in the formula, and it becomes

$$\text{log. } \frac{(n-1)^2(n+2)}{(n-2)(n+1)^2} = 2\text{M}\left\{\frac{2}{n^3-3n} + \tfrac{1}{3}\left(\frac{3}{n^3-3n}\right)^3 + \text{ \&c.}\right\}$$

But the quantity on the left-hand side of this equation is manifestly equal to 2 log. $(n-1)$ + log. $(n+2)$ — log. $(n-2)$ — 2 log. $(n+1)$; therefore, putting P for the series,

$$2\text{M}\left\{\frac{2}{n^3-3n} + \tfrac{1}{3}\left(\frac{2}{n^3-3n}\right)^3 + \tfrac{1}{5}\left(\frac{2}{n^3-3n}\right)^5 + \text{ \&c.}\right\}$$

we have this formula,

$$\text{log.}(n+2) + 2 \text{ log.}(n-1) - \text{log.}(n-2) - 2 \text{ log.}(n+1) = \text{P}.$$

By this formula we may find, with great facility, the logarithm of any one of the four numbers $n-2$, $n-1$, $n+1$, $n+2$, having the logarithms of the other three. We may also employ it in the calculation of logarithms, as in the following example. Let the numbers 5, 6, 7, 8, be substituted successively in the formula; then, observing that log. 6 = log. 2 + log. 3, and log. 8 = 3 log. 2, we have these four equations,

$$\text{log. } 7 + 2 \text{ log. } 2 - 3 \text{ log. } 3 = \frac{2\text{M}}{55} + \frac{2\text{M}}{3\cdot55^3} + \text{ \&c.}$$

$$-2 \text{ log. } 7 + \text{log. } 2 + 2 \text{ log. } 5 = \frac{2\text{M}}{99} + \frac{2\text{M}}{3\cdot99^3} + \text{ \&c.}$$

$$4 \text{ log. } 3 - 4 \text{ log. } 2 - \text{log. } 5 = \frac{2\text{M}}{161} + \frac{2\text{M}}{3\cdot161^3} + \text{ \&c.}$$

$$\text{log. } 5 - 5 \text{ log. } 3 + 2 \text{ log. } 7 = \frac{2\text{M}}{244} + \frac{2\text{M}}{3\cdot244^3} + \text{ \&c.}$$

Let log. 2, log. 3, log. 5, and log. 7, be now considered as

Construction of Logarithms.

four unknown quantities, and by resolving those equations in the usual manner, the logarithms may be determined.

Resuming once more the formula

$$\log.\, z = 2\mathrm{M}\left\{\frac{z-1}{z+1}+\tfrac{1}{3}\left(\frac{z-1}{z+1}\right)^3+\&c.\right\}$$

let $\dfrac{n^2(n+5)(n-5)}{(n+3)(n-3)(n+4)(n-4)}$ be substituted in it instead of z, then, by this substitution, $\dfrac{z-1}{z+1}$ will become $\dfrac{-72}{n^4-25n^2+72}$, and the formula will be transformed to

$$\log.\, \frac{n^2(n+5)(n-5)}{(n+3)(n-3)(n+4)(n-4)}$$
$$=-2\mathrm{M}\left\{\frac{72}{n^4-25n^2+72}+\tfrac{1}{3}\left(\frac{72}{n^4-25n^2+72}\right)^3+\&c.\right\}$$

Hence, putting the latter side of this equation equal to Q, we have this formula,

$$\left.\begin{matrix}2\log.\, n+\log.\,(n+5)+\log.\,(n-5)-\log.\,(n+3)\\ -\log.\,(n-3)-\log.\,(n+4)-\log.\,(n-4)+\mathrm{Q}\end{matrix}\right\}=0$$

which may be applied in the calculation of logarithms in the same manner as the former.

But when it is required to find the logarithm of a higher number, as, for example, 1231, we may proceed as follows.

$$\log.\, 1231=\log.\,(1230+1)=\log.\left\{1230\left(1+\frac{1}{1230}\right)\right\}$$
$$=\log.\, 1230+\log.\left(1+\frac{1}{1230}\right).$$

Again, $\log.\, 1230 = \log.\, 2 + \log.\, 5 + \log.\, 123$, and $\log.\, 123 = \log.\left\{120\left(1+\frac{1}{40}\right)\right\} = \log.\, 120 + \log.\left(1+\frac{1}{40}\right)$, $\log.\, 120 = \log.\,(2^3 \times 3 \times 5) = 3\log.\, 2 + \log.\, 3 + \log.\, 5$. Therefore $\log.\, 1231 = 4\log.\, 2 + \log.\, 3 + 2\log.\, 5 +$

$$\log.\left(1+\frac{1}{40}\right)+\log.\left(1+\frac{1}{1230}\right)$$

Thus the logarithm of the proposed number is expressed by the logarithms of 2, 3, 5, and the logarithms of $1+\frac{1}{40}$, $1+\frac{1}{1230}$, all of which may be easily found by the formulæ already delivered.

New views of Logarithms.

It may be proper here briefly to notice some new views on the doctrine of logarithms, which have been advanced at considerable length by Mr Graves in the *Philosophical Transactions* for 1829. The discovery made by Poisson and Poinsot, in their researches on angular sections, of errors in trigonometrical formulæ usually deemed complete, drew Mr Graves's attention to what he considered analogous defects in logarithmic series. He accordingly professes, in the paper cited, to exhibit in an amended form two fundamental developments, especially that of the one we have given above of the equation $y = r^x$; but the new formulæ are unfortunately exhibited in such an abstruse and indefinite form, as to be quite unintelligible to most readers, and our limits will not admit of introducing them here with a sufficient explanation. The chief objection made to the ordinary series is, that it only gives one value to y for each value of x; whereas, when x is a rational fraction in its lowest terms, y should have as many values of some sort as there are units in the denominator of x. Thus, when $x = \frac{1}{2}$ and $r = 10$, the value of y being $\pm\sqrt{10}$, may be $-3{\cdot}162277$ as well as $+3{\cdot}162277$; but it is surely never meant that y should ever have more than two possible values, or indeed more than one such value, when the denominator of x is odd.

Mr Graves considers the principles employed in this inquiry as presenting a solution of many difficulties, and illustrating peculiarities in the theory of logarithms of negative quantities; and, when applied to geometry, as furnishing the means of tracing the form and developing the properties of curves whose equations involve exponential quantities. He also states that, by their means, various differential and other formulæ usually exhibited in treatises on logarithms may be rendered complete. He combats the opinion that equations which are numerically false may yet be analytically true; and explains the difficulty by reverting to the limitations inherent in the hypothesis on which the developments are founded. In opposition to John Bernoulli and D'Alembert, he maintains that the logarithms of negative numbers are not in general the same as those of positive ones; and hence infers that negative numbers have occasionally even real logarithms. But several objectionable things in Mr Graves's paper have been pointed out by Mr Peacock, in an able article on analysis in the Third Report of the British Association, page 266; and, indeed, until Mr Graves chooses to put his new views in a more definite and intelligible shape, and to express himself in ordinary mathematical language, we suspect his speculations are not likely to meet with a favourable reception.

In addition to the works already mentioned on the theory of logarithms, the following may be consulted, viz.

To most of the larger sets of tables is prefixed an introduction on the theory and construction of logarithms.

Easy mode of computing logarithms by interpolation.

The following short article may be fitly introduced here as an addition to the foregoing treatise. It was written by the late Sir John Leslie for the *Supplement* to the former editions of this work, in which it was inserted under the word INTERPOLATION, in the Addenda.

Few disquisitions in modern mathematics have greater practical utility than those concerning the extension and

Construction of Logarithms.

interpolation of the terms of numerical progressions. But the modes of solution generally proposed, however ingenious and refined, are often too complex for ordinary purposes. We shall therefore point out a procedure of extreme simplicity and most ready application. It will embrace any system of numbers, but seems peculiarly fitted for the computation of logarithms.

Napier first published in 1614 his canon *Mirificus Logarithmorum*, comprised in a very thin and small quarto volume, exhibiting, as far as seven places, the logarithms only of the sines and tangents to every minute of the quadrant; those of the ordinary numbers being left to be deduced from the nearest sines or tangents. In the summer following, Briggs, then professor of geometry in Gresham College at London, who was enchanted by that noble discovery, paid a visit to its illustrious author at Merchiston, in the vicinity of Edinburgh. During an agreeable stay of a month, it was concerted between them to change the natural system of logarithms into another of a more artificial form, but adapted to our denary scale of notation, the labour of the calculation, however, being devolved upon Briggs, as younger, and enjoying robust health. Next season, Briggs performed a second journey to Edinburgh, and showed to Napier a table which he had computed of the new logarithms for the first chiliad or thousand of the series of natural numbers. But the great inventor was now fast declining in years, and expired on the 3d of April 1618. Briggs, employing most skilfully all the abbreviations which ingenuity could devise, prosecuted his most arduous task with such vigour and active perseverance, as to compute, in the space of seven years, to fourteen places of figures, not only the logarithms of the sines and tangents of every degree and centesimal minute of the quadrant, but also the logarithms of thirty chiliads of numbers. These tables were printed in 1624, in a folio volume, entitled *Arithmetica Logarithmica.* In his anxiety, however, to bring out this stupendous work, Briggs contented himself with calculating the logarithms from unit to 20,000, and from 90,000 to 100,000, leaving the computation of the seventy intervening chiliads to be afterwards supplied. The very ingenious author annexed a full explanation of his mode of framing the tables, grounded chiefly on the consideration of differences, and he thus traced the first steps of that important theory. But he likewise gave instructions for the readier filling up of the intermediate logarithms, abridging the toil of calculation no doubt, yet detailing a procedure sufficiently irksome and complicated. "To encourage some skilful persons to perform this task, he offered to furnish them with paper he had by him, ready prepared, and divided into columns proper for that purpose, as likewise to inform them at what part to begin, that they might not interfere one with another; and promised, when the whole was finished, to endeavour to procure a new edition of the work so completed." This slender boon seems not to have tempted the mathematicians in England. In Holland, however, Adrian Vlacq, chancing to meet two years afterwards with a copy of the work, and, prompted only by his patriotic zeal, had the resolution to revise and compute the whole canon, reducing it from fourteen to ten places of figures, which he printed in folio at Gouda, as early as 1628. The same able calculator, only five years afterwards, published, likewise in folio, at Gouda, a very extensive system of logarithmic sines and tangents, to every ten seconds of the quadrant, having restored the sexagesimal subdivision, which Briggs had partly changed into a centesimal one. These two volumes may be deemed a precious *thesaurus* of logarithms, from which succeeding compilers have drawn very liberally. They form the basis of the *Tables* published by Vega at Leipsic in 1794, which, till lately, were the best and completest extant.

But though the *Tables* of Vlacq, carried only to ten places of figures, are sufficiently accurate for every ordinary purpose, and even for the most delicate calculations in astronomy, yet many persons have often regretted that the original system of Briggs was never completed. The celebrated Legendre has employed that table, imperfect as it is, in some of his most refined numerical investigations. It is well known that Mr Baron Maseres devoted a considerable portion of his time and of his fortune to the republication of the works of the early writers on logarithms. In the course of this extensive undertaking, he entertained some thoughts of giving a new edition of the *Arithmetica Logarithmica*, and expressed an earnest wish that the vacant chiliads were filled up. To promote the liberal designs of the baron, the author of this article was induced to bestow some reflection on the subject, and a very simple mode occurred to him, which would have reduced the labour of computing those logarithms to little more than the trouble of mere transcription. But the object of completing the canon was deferred for a time, and afterwards gradually forgotten. The method of interpolation then proposed seems, however, to deserve notice on account of its great simplicity, and its ready application, not only to the immediate object, but to other questions of a similar nature. We shall, therefore, now state the principle, and illustrate its application by a few examples.

The square root of the quantity $a^2 + 1$ is evidently expressed by the continued fraction

$$a + \cfrac{1}{2a + \cfrac{1}{2a + \text{\&c.}}}$$

If two terms only of the fractional part be taken, the expression will become $\sqrt{a^2 + 1} = \frac{4a^3 + 3a}{4a^2 + 1}$, and consequently $\sqrt{\left(\frac{a^2 + 1}{a^2}\right)}$ or $\sqrt{\left(\frac{2a^2 + 2}{2a^2}\right)} = \frac{4a^2 + 3}{4a^2 + 1}$, a very near approximation. Put $b = 2a^2$, and by substitution $\sqrt{\left(\frac{b+2}{b}\right)} = \frac{2b+3}{2b+1}$; wherefore $\frac{1}{2}\log.\frac{b+2}{b} = \log.\frac{2b+3}{2b+1}$. Hence half the differences of the alternate logarithms of the series b, $b + 1$, $b + 2$, &c. added to the logarithm of $2b + 1$, must give the logarithm of $2b + 3$. By this simple process, then, any table of logarithms is carried to double its actual extent through all the odd numbers, those of the even ones being found by the mere addition of the logarithm of 2.

To find the limits of approximation, let three terms of the fractional series be taken, and $\sqrt{\left(\frac{a^2+1}{a^2}\right)} = \frac{8a^4 + 8a^2 + 1}{8a^4 + 4a^2}$, or $\sqrt{\left(\frac{b+2}{b}\right)} = \frac{2b^2 + 4b + 1}{2b^2 + 2b}$

$$= \frac{2b+3}{2b+1}\left(\frac{4b^3 + 10b^2 + 6b + 1}{4b^3 + 10b^2 + 6b}\right)$$

$= \frac{2b+3}{2b+1}\left(1 + \frac{1}{(2b+3)\,(2b+1)b}\right)$. Whence $\frac{1}{2}$ log. $\left(\frac{b+2}{b}\right) = \mathrm{l}\cdot\frac{2b+3}{2b+1} + \mathrm{l}\left(1 + \frac{1}{(2b+3)\,(2b+1)b}\right)$; and, therefore, since this last quantity exceeds unit only by a very minute difference, $\frac{1}{2}\log.\frac{b+2}{2} = \log.\frac{2b+3}{2b+1} + \frac{\mathrm{M}}{(2b+3)\,(2b+1)b}$, where M denotes the modulus of the system. If the number $2b + 3$ or $2b + 1$ be expressed by N, this small correction will amount but to $\frac{M}{\frac{1}{2}N^3}$ or $\frac{2M}{N^3}$. Consequently $\log. \frac{2b+3}{2b+1} = \frac{1}{2} \log. \frac{b+2}{b} - \frac{2M}{N^3}$. It may hence be computed, that the correction on the first approximation will only reach unit in the last figure for the logarithms of numbers under 206 in tables of seven places, for those under 2055 in tables of ten places, and for the logarithms of numbers under 44286 in tables extending to fourteen places.

The corrections required in Briggs's *Tables* of fourteen places will therefore correspond to these limits:

35150	— 2	23151	— 7
30706	— 3	22143	— 8
27899	— 4	21290	— 9
25898	— 5	20557	— 10
24372	— 6	19913	— 11

Suppose it were required to find the logarithms of the odd numbers above 300, to seven places of decimals. Assuming the logarithms of the series of the halves of the intermediate even numbers, let the differences between their alternate terms be taken, and then bisected.

Numbers.	Logarithms.	Alternate Differences.	Their Halves.
150	2·1760913		
151	2·1789769		
152	2·1818436	57523	28761
153	2·1846914	57145	28572
154	2·1875207	56771	28386
155	2·1903317	56403	28201

Numbers.	Logarithms.
301	2·4785665 28761
303	2·4814426 28572
305	2·4842998 28386
307	2·4871384 28201
309	2·4899585

Hence the logarithms of the doubles are formed by the mere addition of these halves.

In this manner the operation may be continued; but, to prevent any accumulation of errors, the logarithms of the composite numbers should serve as standards, being formed by the addition of the logarithms of their several factors. The logarithms of the intermediate even numbers 302, 304, 306, 308, and 310, are easily determined by adding ·3010300 to the logarithms of 151, 152, 153, 154, and 155.

To extend the process a little farther, let Vlacq's logarithms be computed for the numbers above 4000.

19999	4·30100828039700		

The first mode of interpolating, thus derived from the nature of logarithms, and so commodious for their computation, might likewise be deduced from general considerations. Let A, B, C, D, E, &c. represent any series of numbers. If they advance regularly and slowly, their first differences, B — A, C — B, D — C, E — D, &c. may be viewed as constituting an arithmetical progression. Wherefore the sum of the extremes will be equal to that of the mean terms, or $(E - D) + (B - A) = (D - C) + (C - B)$, that is, $E - A = 2D - 2B$, and therefore $D - B = \frac{E - A}{2}$, whence $D = B + \frac{E - A}{2}$. Applying this to the logarithms of eight places of figures, let A, B, C, D, E, &c. represent the logarithms of 500, 501, 502, 503, 504, &c. then $\log. 503 = \log. 501 + \frac{\log. \cdot 504 - \log. 500}{2} = \log. 501 + \frac{\log. 252 - \log. 250}{2} = 2{\cdot}69983773 + \frac{1}{2}(2{\cdot}40140054 - 2{\cdot}39794001) = 2{\cdot}79156799$; the halves of the differences of the alternate logarithms of 250, 251, 252, 253, &c. being thus taken, as before, to compose by their additions the logarithms of the odd numbers 503, 505, 507, &c.

But since $E - A = 2D - 2B$, it follows that $E = A + 2(D - B)$. Wherefore, in any series, the fifth term will be found nearly, by adding to the first term twice the difference between the second and fourth terms. In this way the tables of natural sines, tangents, and secants, could easily be framed. Thus, the logarithmic sines of the successive arcs, 50°, 50° 1′, 50° 2′, and 50° 3′ being given from Vlacq's *Tables*, to find the logarithmic sine of 50° 4′.

Arcs.	Logarithmic Sines.	
50° 0′	9·8842539665	
1′	9·8843599396	2117585
2′	9·8844658502	2
3′	9·8845716981	4235170
4′	9·8846774835	

Here, passing over the middle term, the difference between the logarithmic sines of 50° 1′ and of 50° 3′ is doubled, and added to that of 50°, to form the logarithmic sine of 50° 4′.

But a nearer approximation may be obtained, by supposing the second differences of any series to form the arithmetical progression. The sum of the extreme terms $C - 2B + A$ and $F - 2E + D$ would, therefore, be equal to the sum of the mean terms $D - 2C + B$ and $E - 2D + C$; whence $F - A = 3B + 3E - 2C - 2D$, or $F = A + 3(B + E) - 2(C + D)$. Thus, the natural sines of the successive arcs 30, 31, 32, 34, and 35 degrees may be easily computed to seven places of figures.

Arcs.	Sines.	
30°	·5000000	
31	·5150381	1·0742310 × 3 = 3·2226930
32	·5299193	1·0745583 × 2 = 2·1491166
33	·5446390	
34	·5592929	Difference 1·0735764
35	·5735764	

The sines of 31° and of 34° are here added together, and the sum tripled, and from this amount is taken twice the sum of the sines of 31° and of 33°; the sine of 30° being subtracted from that remainder, leaves finally the sine of 35°.

Employing the same number of terms of the series, a still closer approximation may be discovered, by considering the third differences only as uniformly progressive. Wherefore the extreme differences $D - 3C + 3B - A$ and $F - 3E + 3D - C$ will be together equal to double the middle one, $E - 3D + 3C - B$, and consequently $F - A = 5E - 10D + 10C - 5B$, or $F = A + 5(E - B) - 10(D - C)$.

Hence the logarithms even of low numbers may be computed exact to eight decimal places. Thus, the logarithms of 150, 151, 152, 153, and 154, being given, that of 155 is found by this process:

Numbers.	Logarithms.	
150	2·17609126	
151	2·17897695	854377 × 5 = 4271885
152	2·18189359	284784 × 10 = 2847840
153	2·18469143	
154	2·18752072	Difference, 1424045
155	2·19033170	Add, 2·17609126
		2·19033171

The difference between the logarithms of 151 and 154 is here multiplied by 5, and the difference of the logarithms of 152 and 153 is multiplied by 10; and the excess of the former product above the latter being added to the logarithm of 150, gives the logarithm of 155.

It would obviously be preferable, however, to employ the formula in a modified form for interpolation merely. Hence $D = C + \frac{1}{2}(E - B) + A - F$.

If six terms of the series were given, the seventh could be found to a high degree of accuracy. The sum of the extremes of the progressive third differences being now assumed equal to that of the means, we have $D - 3C + 3B - A + G - 3F + 3E - D = E - 3D + 3C - B + F - 3E + 3D - C$, and by reduction $G - A = 4F - 5E - 5C - 4B$, whence $G = A + 4(F - B) - 5(E - C)$. It seems unnecessary to subjoin any further illustrations; but the very simple methods of interpolation now proposed might be applied with great facility and advantage in various physical researches. In this way much light may be thrown upon the resistance of fluids, and upon the force, the density, and the component heat of steam, at different temperatures.

LOGIC.

Logic is the art of properly conducting reason in the knowledge of things, whether for instructing ourselves or others; or it may be defined the science of human thought, inasmuch as it traces the progress of knowledge, from the first and most simple notions, through all the different combinations of these, and the numerous deductions which result from variously comparing them one with another.

The business of logic, therefore, is to evolve the laws of human thought, and the proper manner of conducting the reason, in order to the attainment of truth and knowledge. It lays open those errors and mistakes which we are apt, through inattention, to run into; and teaches us how to distinguish between truth, and what only wears the resemblance thereof. By these means we become acquainted with the nature, limits, and force of the understanding, and see what things lie within its reach; where we may attain certainty and demonstration; and when we must be contented with probability.

This science is generally divided into four parts, namely, *Perception*, *Judgment*, *Reasoning*, and *Method*.

I.—OF PERCEPTION.

We find ourselves surrounded with a variety of objects, which, acting differently upon our senses, convey different impressions into the mind, and thereby rouse the attention and notice of the understanding. By reflecting, too, on what passes within us, we become sensible of the operations of our own minds, and attend to them as a new set of impressions. But in all this there is only bare *consciousness*. The mind, without proceeding any further, takes notice of the impressions which are made upon it, and views things in order, as they present themselves one after another. This attention of the understanding to the objects acting upon it, whereby it becomes sensible of the impressions they make, is called by logicians *perception*; and the notices themselves, as they exist in the mind, and are there treasured up to become the materials of thinking and knowledge, are distinguished by the names of *ideas, notions, thoughts*, &c. In the article METAPHYSICS it will be shown at large, how the mind, being furnished with ideas, contrives to diversify and enlarge its stock; we have here chiefly to consider the means of making known our thoughts to others, that we may not only understand how knowledge is acquired, but also in what manner it may be communicated with the greatest certainty and advantage.

1. *Of Words, considered as the Signs of Ideas.*

Words the means of recording thoughts.

1. The ideas of which we are conscious, though manifold and various, are nevertheless of themselves unknown to others. But God, designing us for society, has provided us with organs fitted to frame articulate sounds, and given us also a capacity of using those sounds as the signs of internal conceptions. Hence spring words and language; for, having once pitched upon any sound to stand as the mark or sign of an idea in the mind, custom by degrees establishes such a connection between them, that the appearance of the idea in the understanding suggests to our remembrance the sound or name by which it is expressed; as, in like manner, the hearing of the sound excites the idea which it represents. And thus it is easy to conceive how a man may record his own thoughts, and bring them again into view in any succeeding period of life; for this connection being once settled, as the same sounds will always serve to excite the same ideas, if he can but contrive to register his words in the order and disposition in which the actual train of his thoughts presents itself to his imagination, it is evident that he will be able to recall these thoughts at pleasure, and that too in the very manner of their first appearance. Accordingly we find, that the inventions of writing and printing, by enabling us to fix and perpetuate such perishable things as sounds, have also furnished us with the means of giving a kind of permanence to the transactions of the mind, insomuch that they may thereby be subjected to our review like any other objects of nature.

Communication of knowledge.

2. But besides the capacity of recording our thoughts, external signs also enable us to communicate our thoughts to *others*, and to receive information of what passes in *their* minds. For any number of men, having agreed to establish the same sounds as signs of the same ideas, it is apparent that the repetition of these sounds must suggest similar ideas in each, and thus tend to create a perfect correspondence of thoughts. When, for instance, any train of ideas succeed one another in the mind, if the names by which we are wont to express them have been annexed by those with whom we converse to the same order of ideas, nothing is more evident, than that, by repeating those names according to the tenor of our actual conceptions, we shall raise in their minds a similar train of thought. For, by barely attending to what passes within themselves upon hearing the sounds which we repeat, they will also be made aware of the ideas in our understanding. So that we here clearly perceive how a man may communicate his sentiments, knowledge, and discoveries to others, if the language in which he converses be extensive enough to mark all the ideas and operations of his mind. But as this is not always the case, and men are often obliged to invent terms of their own to express new views and conceptions of things, it may be asked, how, in these circumstances, we can become acquainted with the thoughts of another, when he makes use of words with which we have never associated ideas? In order to unveil this mystery, and afford some insight into the foundation, progress, and improvement of language, the following observations are deserving of attention.

Simple ideas.

3. First, it is evident that no word can be to any man the sign of an idea, unless that idea comes to have a real existence in his mind. For names, being only so far intelligible as they denote known internal conceptions; where they have none such answering to them, they are plainly sounds without signification, and of course they convey no instruction or knowledge. But no sooner are the ideas to which they belong raised in the understanding, than, finding it easy to connect them with the established names, we can join in any agreement of this kind established by others, and thereby enjoy the benefit of their discoveries. The first thing therefore to be considered is, how these ideas may be conveyed into the mind; that being there, we may learn to connect them with their appropriate sounds, and so become capable of understanding others when they make use of these sounds in communicating their thoughts. Now, to comprehend this distinctly, it is necessary to attend to the division of our ideas into *simple* and *complex* (see METAPHYSICS). And, firstly, as to our simple ideas, they can find no admission into the mind, except by the two original portals of knowledge, *sensation* and *reflection*. If therefore any of these have as yet no being in the understanding, it is impossible by words or description to excite them there. A man who had never felt the sensation of *heat*, could not be brought to comprehend that sensation by any thing which we might say to explain it. If we would really produce the idea in him, it must be by applying the proper object to his senses, and bringing him within the influence of a heated body. When this is done, and experience has taught him the sensation to which men have annexed the name of *heat*, it then becomes to him the sign of that idea, and he thenceforth understands the meaning of the term, which, before, all the words in the world would not have been sufficient to convey into his mind. The case is the same in respect of light and colours. A man born blind, and thereby deprived of the only means of acquiring the ideas of this class, can never be brought to understand the names by which they are expressed. The reason is obvious. They stand for ideas which have no existence in his mind; and as the organ appropriated to their reception is wanting, all other contrivances are vain, nor can they by any description be suggested to his imagination. But it is quite otherwise in the case of complex notions; for these being no more than certain combinations of simple ideas, put together in various forms, if the original ideas out of which the combinations are made have already obtained admission into the understanding, and the names serving to express them are known, it will be easy, by enumerating the several ideas concerned in the composition, and marking the order and manner in which they are united, to raise any complex conception in the mind. Thus the idea answering to the word *rainbow* may be readily excited in the imagination of another who has never seen the appearance itself, by barely describing the figure, size, position, and order of colours, if we suppose that these several simple ideas, with their names, are sufficiently known to him.

Names of complex ideas definable.

4. And this leads to a second observation upon this subject, namely, that words standing for complex ideas are all *definable*, whereas those by which we denote simple ideas are not; for simple ideas being a sort of secondary perceptions, which have no other entrance into the mind than by sensation or reflection, can only be obtained by experience, from the several objects of nature which are proper to produce in us those perceptions. Words indeed may very well serve to remind us of them, if they have already found admission into the understanding, and their connection with the established names be known; but they can never give them their original being and existence there. And hence it is, that when any one asks the meaning of a word denoting a simple idea, we pretend not to explain it to him by a definition, well knowing that to be impossible; but,

supposing him already acquainted with the idea, and only ignorant of the name by which it is called, we either mention it to him by some other name with which we presume he knows its connection, or appeal to the object from which the idea itself is derived. Thus, were any one to ask the meaning of the word *white*, we should tell him it stood for the same idea as *albus* in Latin, or *blanc* in French; or, if we thought him a stranger to these languages, we might appeal to an object producing the idea, by saying that it denotes the colour which we observe in *snow* or *milk*. But this is by no means a definition of the word, exciting a new idea in his understanding; it is merely a contrivance to remind him of a known idea, and teach him its connection with the established name. For if the ideas after which he inquires have never yet been raised in his mind, as suppose one who had seen no other colours than *black* and *white*, should ask the meaning of the word *scarlet*, it is easy to perceive, that it would be no more possible to make him comprehend it by words, or by a definition, than to introduce the same perception into the imagination of a man born blind. The only method in this case is, to present some object, by looking at which the perception itself may be excited; and thus he will learn both the name and the idea together.

xperi-nce and bserva-on.

5. But how comes it to pass that men agree in the names of their simple ideas, seeing they cannot ascertain the perceptions in one another's minds, nor by words make known these perceptions to others? The effect is produced by experience and observation. Thus finding, for instance, that the name of *heat* is annexed to that sensation which men feel when they approach the fire, we make it also the sign of the sensation excited in us by such an approach, nor have we any doubt that it denotes the same perception in our mind as in theirs. For we are naturally led to imagine, that the same objects operate alike upon the organs of the human body, and produce an uniformity of sensations. No man fancies that the idea raised in him by the taste of *sugar*, and which he calls *sweetness*, differs from that excited in another by the same object; or that *wormwood*, to the relish of which he has applied the epithet *bitter*, produces in another the sensation which he denotes by the word *sweet*. Presuming therefore upon this conformity of perceptions, when they arise from the same objects, we easily agree as to the names of our simple ideas; and if at any time, by a more narrow scrutiny into things, new ideas of this class should come in our way, which we may chuse to express by terms of our own invention, these names are explained, not by a definition, but by referring to the objects whence the ideas themselves have been obtained.

onvey-nce of mplex eas by finitions.

6. Being in this manner furnished with simple ideas, and the names by which they are expressed, the meaning of the terms which stand for complex ideas is easily got at, because the ideas themselves answering to these terms may be conveyed into the mind by definitions; for our complex notions are only certain combinations of simple ideas. When, therefore, these are enumerated, and the manner in which they are united into one conception explained, nothing more is wanting to raise that conception in the understanding; and thus the term denoting it comes of course to be understood. But here it is worth while to reflect a little upon the wise contrivance of nature, in thus furnishing us with the aptest means of communicating our thoughts to others. For were it not so ordered, that we could thus by definitions convey our complex ideas from one to another, it would in many cases be impossible to make them known at all. This is apparent in those ideas which are the proper work of the mind itself; for as they exist only in the understanding, and have no real objects in nature in conformity to which they are framed, if we could not make them known by description, they would for ever lie hid within our own breasts, and be confined to the narrow acquaintance of a single mind. All the fine scenes which arise from time to time in the poet's fancy, and by his lively painting give such entertainment to his readers, were he destitute of this faculty of laying them open to the view of others by words and description, could not extend their influence beyond his own imagination, or give pleasure to any one but the original inventor.

Of great avail towards improving knowledge.

7. There is this further advantage in the ability we enjoy of communicating our complex notions by definitions, that as these constitute by far the largest class of our ideas, and most frequently occur in the progress and improvement of knowledge, so they are by this means imparted with the greatest readiness, than which nothing can tend more to the increase and diffusion of science; for a definition is soon pursued, and if the terms of it are well understood, the idea itself finds an easy admission into the mind. But, in simple perceptions, where we are referred to the objects producing them, if these cannot be come at, as is sometimes the case, the names by which they are expressed must remain empty sounds. As new ideas of this class, however, occur but rarely in the sciences, they seldom create any great obstruction. Yet it is otherwise with our complex notions; for, every step we take leading us into new combinations and views of things, it becomes necessary to explain these to others, before they can be made acquainted with our discoveries; and as the manner of definitions is easy, requiring no apparatus but that of words, which are always ready at hand, we can hence with less difficulty remove such obstacles as might arise from terms of our own invention, when these are made to stand for new complex ideas suggested to the mind by some actual train of thinking. And thus at last we are let into the mystery hinted at in the beginning of this chapter, viz. how we may become acquainted with the thoughts of another, when he makes use of words to which we have as yet joined no ideas. From what has already been said, the answer is obvious. If the terms denote simple perceptions, he must refer us to those objects of nature whence the perceptions themselves are to be obtained; but if they stand for complex ideas, their meaning may be explained by a *definition*.

2. *Of Definition.*

Definition defined.

1. A DEFINITION *is the development and determination of some conception of the mind, answering to the word or term made use of as its sign.* Now as, in exhibiting any idea to another, it is necessary that the description be such as may excite that precise idea in his mind, it is plain that definitions, properly speaking, are not arbitrary, but confined to the representing of certain determinate settled notions, such, namely, as are annexed by the speaker or writer to the words he employs. As nevertheless it is universally allowed that the signification of words is perfectly voluntary, and not the effect of any natural and necessary connection between them and the ideas for which they stand, some may perhaps wonder why definitions are not so likewise. In order, therefore, to unravel this difficulty, and show distinctly what is and what is not arbitrary in speech, we must carefully distinguish between the connection of our words and ideas, and the unfolding of the ideas themselves.

Connection between words and ideas.

2. First, as to the connection of words and ideas; this, it is evident, is purely an arbitrary institution. When, for instance, we have in our minds the idea of any particular species of metals, the calling it by the name *gold* is an effect of the voluntary choice of men speaking the same language, and not of any peculiar aptness in that sound to express that idea. Other nations we find make use of different sounds, and with the same effect. Thus

aurum denotes the same idea in Latin, and *or* in French; and even the word *gold* itself would have as well served to express the idea of that metal which we call *silver*, had custom in the beginning so established it.

Ideas limited to representing the appearance by which they are distinguished.

3. But although we are thus entirely at liberty to connect any idea with any sound, yet it is quite otherwise in unfolding the ideas themselves; for every idea having a precise appearance of its own, by which it is distinguished from every other idea, it is manifest, that in laying it open to others, we must study such a description as shall exhibit that peculiar appearance. When we have formed to ourselves the idea of a figure bounded by four equal sides, joined together at right angles, we are at liberty to express that idea by any sound, and call it either a *square* or a *triangle.* But whichever of these names we use, so long as the idea is the same, the description by which we would signify it to another must likewise remain so. Let it be called *square* or *triangle*, it is still a figure having four equal sides, and all its angles right ones. Hence we clearly see what is and what is not arbitrary in the use of words. The establishing any sound as the mark of some determinate idea in the mind, is the effect of free choice, and of a voluntary combination amongst men; and as different nations make use of different sounds to denote the same ideas, hence proceed all that variety of languages which we meet with in the world. But when a connection between our ideas and words is once settled, the unfolding of the idea answering to any word, which properly constitutes a definition, is by no means an arbitrary thing. In this case we are bound to exhibit the precise conception which either the use of language, or our own particular choice, has annexed to the term we employ.

Causes of obscurity. Verbal definitions.

4. And thus it appears, that definitions, considered as descriptions of ideas in the mind, are steady and invariable, being confined to the representation of those precise ideas. But then, in the application of definitions to particular names, we are altogether left to our own free choice; because, as the connecting of any idea with any sound is a perfectly arbitrary institution, the applying the description of that idea to that sound must be so likewise. When, therefore, logicians tell us that the definition of the name is arbitrary, they mean no more than this, That as different ideas may be connected with any term, according to the pleasure of him who employs it, in like manner may different descriptions be applied to the term, suitable to the ideas so connected. But this connection being settled, and the term considered as the sign of some fixed idea in the understanding, we are no longer left to arbitrary explanations, but must study such a description as corresponds with that precise idea. Now, this alone, according to what has been before laid down, ought to be accounted a definition. What seems to have occasioned no small confusion in this matter, is, that many explanations of words, where no idea is unfolded, but the connection between some word and idea is merely asserted, have yet been dignified with the name of definitions. Thus, when we say that *a clock is an instrument by which we measure time*, that is by some called a definition; and yet it is plain that we are beforehand supposed to have an idea of this instrument, and only taught that the word *clock* serves in common language to denote that idea. By this rule all explanations of words in our dictionaries would be definitions, nay, the names of even simple ideas might be thus described. *White*, we may say, is the colour we observe in snow or milk; *heat*, the sensation produced by approaching the fire; and so in innumerable other instances. But these, and all others of a similar kind, are by no means definitions, exciting new ideas in the understanding, but merely contrivances to remind us of known ideas, and to teach their connection with the established names.

Complex ideas alone capable of definition. Real definitions.

5. But, in definitions properly so called, we have first to consider the term we use as the sign of some inward conception, either annexed to it by custom, or by our own free choice; and then the business of the definition is to unfold and explicate that idea. As therefore the whole art consists in giving just and true copies of our ideas, a definition is said to be made perfect, when it serves distinctly to excite the idea described in the mind of another, even supposing him to have been previously unacquainted with it. This point being settled, then, let us next inquire what those ideas are which are capable of being thus unfolded. And, in the first place, it is evident that all our simple ideas are necessarily excluded. We have already seen that experience alone is to be consulted here, insomuch that if either the objects whence they are derived come not in our way, or the avenues appointed by nature for their reception are wanting, no description can be sufficient to convey them into the mind. But where the understanding is already supplied with these original and primitive conceptions, as they may be united together in an infinity of different forms, so may all their several combinations be distinctly laid open, by enumerating the simple ideas concerned in the various combinations, and tracing the order and manner in which they are linked together in composition. Now these combinations of simple notices constitute what we call complex notions; whence it is evident, that complex ideas, and these alone, admit of that kind of description which goes by the name of definition.

6. Definitions, then, are pictures or representations of our ideas; and as these representations are only possible when the ideas themselves are complex, it is obvious to remark, that definitions cannot have place, except where we make use of terms standing for such complex ideas. But our complex ideas being, as we have said, nothing more than different combinations of simple ideas, we know and comprehend them perfectly, when we know the several simple ideas of which they consist, and can so put them together in our minds as may be necessary towards the framing of that peculiar connection which gives every idea its distinct and proper appearance.

Things required in a definition.

7. Two things are therefore required in every definition. The first is, that all the original ideas, out of which the complex one is formed, be distinctly enumerated; and the second is, that the order and manner of combining them into one conception be clearly explained. Where a definition has these requisites, nothing is wanting to its perfection; because every one who reads it and understands the terms, seeing at once what ideas he is to join together, and also in what manner, can at pleasure form in his own mind the complex conception answering to the term defined. Let us, for instance, suppose the word *square* to stand for that idea by which we represent to ourselves a figure whose sides subtend quadrants of a circumscribed circle. The parts of this idea are the sides bounding the figure. These must be four in number, and all equal amongst themselves, because they are each to subtend a fourth part of the same circle. But, besides these component parts, we must also take notice of the manner of putting them together, if we would exhibit the precise idea for which the word *square* here stands; for, four equal right lines, anyhow joined, will not subtend quadrants of a circumscribed circle. A figure with this property must have its sides standing also at right angles. Taking in this last consideration, therefore, respecting the manner of combining the parts, the idea is fully described, and the definition thereby rendered complete; for a figure bounded by four equal sides, joined together at right angles, has the property required, and is moreover the only right-lined figure to which that property belongs.

How to arrive at just definitions.

8. It will now be obvious to every one in what manner we ought to proceed, in order to arrive at just and adequate definitions. First, we are to take an exact view of

the idea to be described; trace it to its original principles; and mark the several simple perceptions which enter into the composition of it. Secondly, we are to consider the particular manner in which these elementary ideas are combined, in order to form that precise conception for which the term we make use of stands. When this is done, and the idea is wholly unravelled, we have nothing more to do than fairly to transcribe the appearance it makes to our own minds. Such a description, by distinctly exhibiting the order and number of our primitive conceptions, cannot fail to excite, at the same time, in the mind of every one who reads it, the complex idea resulting from them; and therefore it attains the true and proper end of a definition.

3. *Of the Composition and Resolutions of our Ideas, and the Rules of Definition thence arising.*

rocedure com- ounding eas.

1. The rule laid down in the foregoing chapter is general, extending to all possible cases, and is indeed that to which alone we can have recourse where any doubt or difficulty may arise. It is not, however, necessary that we should practise it in every particular instance. Many of our ideas are extremely complicated, insomuch that to enumerate all the simple perceptions out of which they are formed would be a very troublesome and tedious task. For this reason logicians have established certain compendious rules of defining, which it may not be amiss here to give some account of. But in order to the better understanding of what follows, it will be necessary to keep in view, that there is a certain gradation in the composition of our ideas. The mind of man is very limited in its apprehension, and cannot take in a great number of objects at once. We are therefore obliged to proceed gradually, and make our first advances subservient to those which follow. Thus, in forming our complex notions, we begin at first with but a few simple ideas, such as we can manage with ease, and unite together into one conception. When we are provided with a sufficient stock of these, and have by habit and use rendered them familiar to our minds, they become the component parts of other ideas still more complicated, and form what may be called a second order of compound notions. This process, it is evident, may be continued to any degree of composition we please, mounting from one stage to another, and enlarging, as we ascend, the number of combinations.

leas of is class st com- ehended hen we vance adually.

2. But, in a series of this kind, whosoever would make himself perfectly acquainted with the last and highest order of ideas, must find it expedient to proceed gradually through all the intermediate steps. For, were he to take any very composite idea to pieces, and, without regard to the several classes of simple perceptions which have already been formed into distinct combinations, break it down at once into its original elements, the number would be so great as perfectly to confound the imagination, and overcome the utmost reach and capacity of the mind. When we observe a prodigious multitude of men huddled together in crowds, without order or any regular position, we find it impossible to arrive at an exact knowledge of their number. But if they are formed into separate battalions, and so stationed as to fall within the leisurely survey of the eye, by viewing them successively and in order, we may come to an easy and certain determination. It is the same in regard to complex ideas. When the original perceptions out of which they are framed are very numerous, it is not enough that we take a view of them in loose and scattered bodies; we must form them into distinct classes, and unite these classes in a just and orderly manner, before we can arrive at a true knowledge of the compound notions resulting from them.

Definitions should keep pace with ideas.

3. This gradual progress of the mind to its composite notions, through a variety of intermediate steps, plainly points out the manner of conducting the definitions by which these notions may be conveyed into the minds of others; for, as the series commences with simple and easy combinations, and advances through a succession of different orders, rising one above another in the degree of composition, it is evident that, in a train of definitions expressing these ideas, a similar gradation is to be observed. Thus the complex ideas of the lowest order can no otherwise be described than by enumerating the simple ideas out of which they are formed, and explaining the manner of their union. But, in the second, or any other succeeding order, as they are formed out of those gradual combinations, it is not necessary, in describing them, to mention one by one all the simple ideas of which they are composed. They may be more distinctly and briefly unfolded by enumerating the compound ideas of a lower order, of whose union they are the result, and which are all supposed to be already known in consequence of previous definitions. Here then it is that the logical method of definition takes place; which, that it may be the better understood, we shall explain somewhat more particularly the several steps and gradations of the mind in compounding its ideas, and thence deduce that peculiar form of definition which logicians have thought proper to establish.

Procedure from particular to general ideas.

4. All the ideas we receive from the several objects of nature that surround us represent distinct individuals; and these individuals, when compared together, are found in certain particulars to resemble each other. Hence, by collecting the resembling particulars into one conception, we form the notion of a *species*. And here let it be observed, that this last idea is less complicated than that by which we represent any of the particular objects contained under it; for the idea of the species excludes the peculiarities of the several individuals, and embraces such properties only as are common to all. Again, by comparing several species together, and observing their resemblance, we form the idea of a *genus;* where, in the same manner as before, the composition is lessened, because we leave out what is peculiar to the several species compared, and retain only the particulars in which they agree. It is easy to conceive the mind proceeding thus from one step to another, and advancing through several classes of general notions, until at last it arrives at the highest genus of all, denoted by the word *being*, where the idea of existence alone is concerned.

Conduct of the mind in compounding its ideas.

5. In this procedure we observe the mind unravelling a complex idea, and tracing it in the ascending scale, from greater or less degrees of composition, until it terminates in one simple perception. But if we take the series the contrary way, and, beginning with the last or highest genus, carry our view downwards, through all the inferior genera and species, to the individuals, we shall thereby arrive at a distinct apprehension of the conduct of the understanding in the composition of its ideas; for, in the several classes of our perceptions, the highest in the scale is for the most part that which is made up of but a few simple ideas, such as the mind can take in and survey with ease. This first general notion, when branched out into the different subdivisions contained under it, has in every one of them something peculiar, by which they are distinguished amongst themselves; insomuch that, in descending from the genus to the species, we always superadd some new idea, and thereby increase the degree of composition. Thus the idea denoted by the word *figure* is of a very general nature, and composed of but few simple perceptions, as implying no more than space everywhere bounded. But if we descend further, and consider the boundaries of this space, as that they may be either lines or surface, we shall fall into the several species of figure. For where the space is bounded by one or more surfaces, we

mutable truths. If it be true that the whole is equal to all its parts, it must be so unchangeably; because the relation of equality, being attached to the ideas themselves, must ever intervene where the same ideas are compared. Of this nature are all the truths of natural religion, morality, and mathematics, and, in general, whatever may be gathered from the bare view and consideration of our ideas.

2. Experience.

4. The second ground of human judgment is Experience; from which we are led to infer the existence of those objects that surround us, and fall under the immediate notice of our senses. When we see the sun, or cast our eyes towards a building, we not only have perceptions of these objects within ourselves, but ascribe to them a real existence independent of the percipient mind. It is also by the information of the senses that we judge of the qualities of bodies; as when we say that "snow is white, fire hot, or steel hard." For as we are wholly unacquainted with the internal structure and constitution of the bodies which produce these sensations in us, and are unable to trace any connection between that structure and the sensations themselves, it is evident that we build our judgments altogether upon observation, ascribing to bodies such qualities as are answerable to the perceptions which they excite in us. Not that we ever suppose the qualities of bodies to be things of the same nature with our perceptions; for there is nothing in fire similar to the sensation of heat, or in a sword similar to that of pain; but when different bodies excite in our minds similar perceptions, we necessarily ascribe to these bodies, not only an existence independent of us, but likewise similar qualities, of which it is the nature to produce similar perceptions in the human mind. But this is not the only advantage derived from experience; for to that too we are indebted for all our knowledge regarding the co-existence of sensible qualities in objects, and the operations of bodies one upon another. Ivory, for instance, is hard and elastic; this we know by experience, and indeed by experience alone. For, being altogether strangers to the true nature both of elasticity and hardness, we cannot by the bare contemplation of our ideas determine how far the one necessarily implies the other, or whether there may not be a repugnance between them. But when we observe that both exist in the same object, we are then assured from experience that they are not incompatible; and when we also find that a stone is hard and not elastic, and that air though elastic is not hard, we likewise conclude upon the same foundation that the ideas are not necessarily conjoined, but may exist separately in different objects. In like manner, with regard to the operations of bodies upon one another, it is evident that our knowledge this way is all derived from observation. *Aqua regia* dissolves gold, as has been found by frequent trial, nor is there any other way of arriving at the discovery. Naturalists may tell us, if they please, that the parts of *aqua regia* are of a texture apt to insinuate between the corpuscles of gold, and thereby loosen and burst them asunder. If this be a true account of the matter, it will notwithstanding be allowed that our conjecture in regard to the conformation of these bodies is deduced from the experiment, and not the experiment from the conjecture. It was not from any previous knowledge of the intimate structure of *aqua regia* and *gold*, and the aptness of their parts to act or to be acted upon, that we came by the conclusion above mentioned. The internal constitution of bodies is in a manner wholly unknown to us; and could we even surmount this difficulty, yet, as the separation of the parts of gold implies something like an active force in the *menstruum*, and we are unable to conceive how the latter comes to be possessed of this activity, the effect must be owned to be altogether beyond our comprehension. But when repeated trials had once confirmed it, insomuch that it was admitted as an established truth in natural knowledge, it then became easy for men to spin out theories of their own invention, and contrive such a structure of parts, both for *gold* and *aqua regia*, as would best serve to explain the phenomenon upon the principles of that system of philosophy, whatever it might be, which they had adopted.

5. From what has been said, it is evident that as intuition is the foundation of what we call *scientific*, so experience is the foundation of what we call *natural* knowledge. For this last being wholly concerned with objects of sense, or those bodies that constitute the natural world, and their properties, as far as we can discover them, being to be traced only by a long and painful series of observations, it is apparent, that, in order to improve this branch of knowledge, we must betake ourselves to the method of trial and experiment.

6. But though experience is what we may term the immediate foundation of natural knowledge, yet with respect to particular persons its influence is very narrow and confined. The bodies that surround us are numerous, many of them lie at a great distance, and some are quite beyond our reach. Life is so short, and so crowded with cares, that but little time is left for any single man to employ himself in unfolding the mysteries of nature. Hence it is necessary to admit many things upon the testimony of others, which by this means becomes the foundation of a great part of our knowledge of body. No man doubts of the power of *aqua regia* to dissolve gold, though perhaps he never himself made the experiment. In these, therefore, and such like cases, we judge of the facts and operations of nature upon the mere ground of testimony. However, as we can always have recourse to experiment where any doubt or scruple arises, this is justly considered as the true foundation of natural philosophy, being indeed the ultimate support upon which our assent rests, and to which we appeal when the highest degree of evidence is required.

7. But there are many facts which do not admit of an appeal to the senses; and in this case testimony is the true and only foundation of our judgments. All human actions, of whatever kind, when considered as already past, are of the nature here described; because having now no longer any existence, both the facts themselves, and the circumstances attending them, can be known only from the relations of those who had sufficient opportunities of arriving at the truth. *Testimony*, therefore, is justly accounted a third ground of human judgment; and as from the other two we have deduced *scientific* and *natural* knowledge, so we may from this derive *historical*, by which we mean, not merely a knowledge of the civil transactions of states and kingdoms, but of all facts whatsoever, where testimony is the ultimate foundation of our belief.

2. *Of Affirmative and Negative Propositions.*

1. Whilst the comparing of our ideas is considered merely as an act of the mind, assembling them together, and joining or disjoining them according to the result of its perceptions, we call it *judgment;* but when our judgments are put into words, they then bear the name of *propositions*. A proposition, therefore, is a sentence expressing some judgment of the mind, by which two or more ideas are affirmed to agree or disagree. Now, as our judgments include at least two ideas, one of which is affirmed or denied of the other, so must a proposition have terms answering to these ideas. The idea of which we affirm or deny, and of course the term expressing that idea, is called the *subject* of the proposition. The idea affirmed or denied, as also the term answering it, is called the *predicate*. Thus, in the proposition, "God is omnipotent," *God* is the subject, it being of him that we affirm omnipotence, and *om-*

Judgment.

nipotent is the predicate, because we affirm that the idea expressed by that word belongs to God.

The copu-la.

2. But as in propositions ideas are either joined or disjoined, it is not enough to have terms expressing those ideas, unless we have also some words to denote their agreement or disagreement. That word in a proposition which connects two ideas together, is called the *copula;* and if a negative particle be annexed, we thereby understand that the ideas are disjoined. The *substantive verb* is commonly made use of for the copula, as in the above-mentioned proposition, "God is omnipotent," where *is* represents the copula, and signifies the agreement of the ideas of *God* and *omnipotence.* But if we mean to separate two ideas, then, besides the substantive verb, we must also use some particle of negation to express this repugnance. The proposition, "Man is not perfect," may serve as an example of this kind; for here the notion of *perfection* being removed from the idea of *man,* the negative particle *not* is inserted after the copula, to signify the disagreement between the subject and the predicate.

3. Every proposition necessarily consists of these three parts, but then it is not alike needful that they be all severally expressed in words; because the copula is often included in the term of the predicate, as when we say "He sits," which imports the same as "He is sitting." In the Latin language a single word has often the force of a whole sentence. Thus *ambulat* is the same as *ille est ambulans; amo,* as *ego sum amans;* and so in innumerable other instances, by which it appears that we are not so much to regard the number of words in a sentence, as the ideas which they represent, and the manner in which they are put together. For wherever two ideas are joined or disjoined in an expression, though of but a single word, it is evident that we have a subject, predicate, and copula, and of consequence a complete proposition.

4. When the mind joins two ideas, we call it an *affirmative* judgment; when it separates them, a *negative;* and as any two ideas compared together must necessarily either agree or not agree, it is evident that all our judgments fall under these two divisions. Hence, likewise, the propositions expressing these judgments are all either affirmative or negative. An affirmative proposition connects the predicate with the subject, as, "A stone is heavy;" a negative proposition separates them, as "God is not the author of evil." *Affirmation,* therefore, is the same as joining two ideas together; and this is effected by means of the copula. *Negation,* on the contrary, marks the repugnance between the ideas compared, in which case a negative particle must be called in to show that the connection included in the copula does not take place.

5. Hence we see the reason of the rule commonly laid down by logicians, That in all negative propositions the negation ought to affect the copula. For as the copula, when placed by itself between the subject and the predicate, manifestly binds them together, it is evident, that in order to render a proposition negative, the particles of negation must enter it in such a manner as to destroy this union. In a word, two ideas are only disjoined in a proposition when the negative particle may be so referred to the copula as to break the affirmation included in it, and undo that connection it would otherwise establish. When we say, for instance, "No man is perfect," take away the negation, and the copula of itself plainly unites the ideas in the proposition. But as this is the very reverse of what is intended, a negative mark is added, to show that this union does not take place here. The negation, therefore, by destroying the effect of the copula, changes the very nature of the proposition, insomuch that, instead of binding two ideas together, it denotes their separation. On the contrary, in this sentence, "The man who departs not from an upright behaviour is beloved of God," the predicate *beloved of God* is evidently affirmed of the subject an *upright man;* so that, notwithstanding the negative particle, the proposition is still affirmative. The reason is plain. The negation here affects not the copula, but, constituting properly a part of the subject, serves, with other terms in the sentence, to form one complex idea, of which the predicate *beloved of God* is directly affirmed.

3. *Of Universal and Particular Propositions.*

Division of propositions.

1. The next considerable division of propositions is that into *universal* and *particular.* Our ideas, according to what has been already observed, are all singular as they enter the mind, and represent individual objects. But as by abstraction we can render them universal, so as to comprehend a whole class of things, and sometimes several classes at once, hence the terms expressing these ideas must be in like manner universal. If, therefore, we suppose any general term to become the subject of a proposition, it is evident, that whatever is affirmed of the abstract idea belonging to that term, may be affirmed of all the individuals to which that idea extends. Thus, when we say, "Men are mortal," we consider mortality, not as confined to one or any number of particular men, but as what may be affirmed without restriction of the whole species. By this means the proposition becomes as general as the idea which forms the subject of it, and indeed derives its universality entirely from that idea, being more or less so according as this may be extended to more or fewer individuals. But it is further to be observed of these general terms, that they sometimes enter a proposition in their full latitude, as in the example above given, and sometimes appear with a mark of limitation. In this last case we are given to understand that the predicate agrees not to the whole universal idea, but only to a part of it; as in the proposition, "Some men are wise." Here wisdom is not affirmed of every particular man, but is restricted to a few of the human species.[1]

Propositions are universal where the subject is so.

2. Now, from this different appearance of the general idea which constitutes the subject of any judgment, arises the division of propositions into *universal* and *particular.* An universal proposition is that in which the subject is some general term taken in its full latitude, insomuch that the predicate agrees to all the individuals comprehended under it if it denotes a proper species, and to all the several species and their individuals if it marks an idea of a higher order. The words *all, every, no, none,* &c. are the proper signs of this universality; and as they seldom fail to accompany general truths, so they form the most obvious criterion by which to distinguish them. "All animals have a power of beginning motion." This is an universal proposition, as we know from the word *all* prefixed to the subject *animals,* which denotes that it must be taken in its full extent. Hence the power of beginning motion may be affirmed of all the different species of animals.

Particular propositions.

3. A *particular* proposition has in like manner some general term for its subject, but with a mark of limitation added, to denote that the predicate agrees only to some of the individuals comprehended under a species, or to one

---

[1] See the preceding note, where it is demonstrated that the *terms* alone, and not the *ideas,* are in reality *general.* The term *man* is equally applicable to every individual of the human race; and therefore, what is affirmed or denied of *men* in general, is affirmed or denied of all the individuals, without regard to their discriminating qualities. *Some* is a definitive word (see GRAMMAR), which, prefixed to the word *man,* limits the signification of that *general term;* and therefore what is affirmed of *some men,* is affirmed only of *part* of the race, but that part itself is not ascertained.

mutable truths. If it be true that the whole is equal to all its parts, it must be so unchangeably; because the relation of equality, being attached to the ideas themselves, must ever intervene where the same ideas are compared. Of this nature are all the truths of natural religion, morality, and mathematics, and, in general, whatever may be gathered from the bare view and consideration of our ideas.

2. Experience.

4. The second ground of human judgment is Experience; from which we are led to infer the existence of those objects that surround us, and fall under the immediate notice of our senses. When we see the sun, or cast our eyes towards a building, we not only have perceptions of these objects within ourselves, but ascribe to them a real existence independent of the percipient mind. It is also by the information of the senses that we judge of the qualities of bodies; as when we say that "snow is white, fire hot, or steel hard." For as we are wholly unacquainted with the internal structure and constitution of the bodies which produce these sensations in us, and are unable to trace any connection between that structure and the sensations themselves, it is evident that we build our judgments altogether upon observation, ascribing to bodies such qualities as are answerable to the perceptions which they excite in us. Not that we ever suppose the qualities of bodies to be things of the same nature with our perceptions; for there is nothing in fire similar to the sensation of heat, or in a sword similar to that of pain; but when different bodies excite in our minds similar perceptions, we necessarily ascribe to these bodies, not only an existence independent of us, but likewise similar qualities, of which it is the nature to produce similar perceptions in the human mind. But this is not the only advantage derived from experience; for to that too we are indebted for all our knowledge regarding the co-existence of sensible qualities in objects, and the operations of bodies one upon another. Ivory, for instance, is hard and elastic; this we know by experience, and indeed by experience alone. For, being altogether strangers to the true nature both of elasticity and hardness, we cannot by the bare contemplation of our ideas determine how far the one necessarily implies the other, or whether there may not be a repugnance between them. But when we observe that both exist in the same object, we are then assured from experience that they are not incompatible; and when we also find that a stone is hard and not elastic, and that air though elastic is not hard, we likewise conclude upon the same foundation that the ideas are not necessarily conjoined, but may exist separately in different objects. In like manner, with regard to the operations of bodies upon one another, it is evident that our knowledge this way is all derived from observation. *Aqua regia* dissolves gold, as has been found by frequent trial, nor is there any other way of arriving at the discovery. Naturalists may tell us, if they please, that the parts of *aqua regia* are of a texture apt to insinuate between the corpuscles of gold, and thereby loosen and burst them asunder. If this be a true account of the matter, it will notwithstanding be allowed that our conjecture in regard to the conformation of these bodies is deduced from the experiment, and not the experiment from the conjecture. It was not from any previous knowledge of the intimate structure of *aqua regia* and *gold*, and the aptness of their parts to act or to be acted upon, that we came by the conclusion above mentioned. The internal constitution of bodies is in a manner wholly unknown to us; and could we even surmount this difficulty, yet, as the separation of the parts of gold implies something like an active force in the *menstruum*, and we are unable to conceive how the latter comes to be possessed of this activity, the effect must be owned to be altogether beyond our comprehension. But when repeated trials had once confirmed it, insomuch that it was admitted as an established truth in natural knowledge, it then became easy for men to spin out theories of their own invention, and contrive such a structure of parts, both for *gold* and *aqua regia*, as would best serve to explain the phenomenon upon the principles of that system of philosophy, whatever it might be, which they had adopted.

5. From what has been said, it is evident that as intuition is the foundation of what we call *scientific*, so experience is the foundation of what we call *natural* knowledge. For this last being wholly concerned with objects of sense, or those bodies that constitute the natural world, and their properties, as far as we can discover them, being to be traced only by a long and painful series of observations, it is apparent, that, in order to improve this branch of knowledge, we must betake ourselves to the method of trial and experiment.

6. But though experience is what we may term the immediate foundation of natural knowledge, yet with respect to particular persons its influence is very narrow and confined. The bodies that surround us are numerous, many of them lie at a great distance, and some are quite beyond our reach. Life is so short, and so crowded with cares, that but little time is left for any single man to employ himself in unfolding the mysteries of nature. Hence it is necessary to admit many things upon the testimony of others, which by this means becomes the foundation of a great part of our knowledge of body. No man doubts of the power of *aqua regia* to dissolve gold, though perhaps he never himself made the experiment. In these, therefore, and such like cases, we judge of the facts and operations of nature upon the mere ground of testimony. However, as we can always have recourse to experiment where any doubt or scruple arises, this is justly considered as the true foundation of natural philosophy, being indeed the ultimate support upon which our assent rests, and to which we appeal when the highest degree of evidence is required.

3. Test mony.

7. But there are many facts which do not admit of an appeal to the senses; and in this case testimony is the true and only foundation of our judgments. All human actions, of whatever kind, when considered as already past, are of the nature here described; because having now no longer any existence, both the facts themselves, and the circumstances attending them, can be known only from the relations of those who had sufficient opportunities of arriving at the truth. *Testimony*, therefore, is justly accounted a third ground of human judgment; and as from the other two we have deduced *scientific* and *natural* knowledge, so we may from this derive *historical*, by which we mean, not merely a knowledge of the civil transactions of states and kingdoms, but of all facts whatsoever, where testimony is the ultimate foundation of our belief.

2. *Of Affirmative and Negative Propositions.*

The su ject an predica of a pr sition.

1. Whilst the comparing of our ideas is considered merely as an act of the mind, assembling them together, and joining or disjoining them according to the result of its perceptions, we call it *judgment;* but when our judgments are put into words, they then bear the name of *propositions*. A proposition, therefore, is a sentence expressing some judgment of the mind, by which two or more ideas are affirmed to agree or disagree. Now, as our judgments include at least two ideas, one of which is affirmed or denied of the other, so must a proposition have terms answering to these ideas. The idea of which we affirm or deny, and of course the term expressing that idea, is called the *subject* of the proposition. The idea affirmed or denied, as also the term answering it, is called the *predicate*. Thus, in the proposition, "God is omnipotent," *God* is the subject, it being of him that we affirm omnipotence, and *om-*

nipotent is the predicate, because we affirm that the idea expressed by that word belongs to God.

2. But as in propositions ideas are either joined or disjoined, it is not enough to have terms expressing those ideas, unless we have also some words to denote their agreement or disagreement. That word in a proposition which connects two ideas together, is called the *copula;* and if a negative particle be annexed, we thereby understand that the ideas are disjoined. The *substantive verb* is commonly made use of for the copula, as in the above-mentioned proposition, "God is omnipotent," where *is* represents the copula, and signifies the agreement of the ideas of *God* and *omnipotence.* But if we mean to separate two ideas, then, besides the substantive verb, we must also use some particle of negation to express this repugnance. The proposition, "Man is not perfect," may serve as an example of this kind; for here the notion of *perfection* being removed from the idea of *man*, the negative particle *not* is inserted after the copula, to signify the disagreement between the subject and the predicate.

3. Every proposition necessarily consists of these three parts, but then it is not alike needful that they be all severally expressed in words; because the copula is often included in the term of the predicate, as when we say "He sits," which imports the same as "He is sitting." In the Latin language a single word has often the force of a whole sentence. Thus *ambulat* is the same as *ille est ambulans; amo*, as *ego sum amans;* and so in innumerable other instances, by which it appears that we are not so much to regard the number of words in a sentence, as the ideas which they represent, and the manner in which they are put together. For wherever two ideas are joined or disjoined in an expression, though of but a single word, it is evident that we have a subject, predicate, and copula, and of consequence a complete proposition.

4. When the mind joins two ideas, we call it an *affirmative* judgment; when it separates them, a *negative;* and as any two ideas compared together must necessarily either agree or not agree, it is evident that all our judgments fall under these two divisions. Hence, likewise, the propositions expressing these judgments are all either affirmative or negative. An affirmative proposition connects the predicate with the subject, as, "A stone is heavy;" a negative proposition separates them, as "God is not the author of evil." *Affirmation*, therefore, is the same as joining two ideas together; and this is effected by means of the copula. *Negation*, on the contrary, marks the repugnance between the ideas compared, in which case a negative particle must be called in to show that the connection included in the copula does not take place.

5. Hence we see the reason of the rule commonly laid down by logicians, That in all negative propositions the negation ought to affect the copula. For as the copula, when placed by itself between the subject and the predicate, manifestly binds them together, it is evident, that in order to render a proposition negative, the particles of negation must enter it in such a manner as to destroy this union. In a word, two ideas are only disjoined in a proposition when the negative particle may be so referred to the copula as to break the affirmation included in it, and undo that connection it would otherwise establish. When we say, for instance, "No man is perfect," take away the negation, and the copula of itself plainly unites the ideas in the proposition. But as this is the very reverse of what is intended, a negative mark is added, to show that this union does not take place here. The negation, therefore, by destroying the effect of the copula, changes the very nature of the proposition, insomuch that, instead of binding two ideas together, it denotes their separation. On the contrary, in this sentence, "The man who departs not from an upright behaviour is beloved of God," the predicate *beloved of God* is evidently affirmed of the subject an *upright man;* so that, notwithstanding the negative particle, the proposition is still affirmative. The reason is plain. The negation here affects not the copula, but, constituting properly a part of the subject, serves, with other terms in the sentence, to form one complex idea, of which the predicate *beloved of God* is directly affirmed.

Of Judgment.

3. *Of Universal and Particular Propositions.*

Division of propositions.

1. The next considerable division of propositions is that into *universal* and *particular.* Our ideas, according to what has been already observed, are all singular as they enter the mind, and represent individual objects. But as by abstraction we can render them universal, so as to comprehend a whole class of things, and sometimes several classes at once, hence the terms expressing these ideas must be in like manner universal. If, therefore, we suppose any general term to become the subject of a proposition, it is evident, that whatever is affirmed of the abstract idea belonging to that term, may be affirmed of all the individuals to which that idea extends. Thus, when we say, "Men are mortal," we consider mortality, not as confined to one or any number of particular men, but as what may be affirmed without restriction of the whole species. By this means the proposition becomes as general as the idea which forms the subject of it, and indeed derives its universality entirely from that idea, being more or less so according as this may be extended to more or fewer individuals. But it is further to be observed of these general terms, that they sometimes enter a proposition in their full latitude, as in the example above given, and sometimes appear with a mark of limitation. In this last case we are given to understand that the predicate agrees not to the whole universal idea, but only to a part of it; as in the proposition, "Some men are wise." Here wisdom is not affirmed of every particular man, but is restricted to a few of the human species.[1]

Propositions are universal where the subject is so.

2. Now, from this different appearance of the general idea which constitutes the subject of any judgment, arises the division of propositions into *universal* and *particular.* An universal proposition is that in which the subject is some general term taken in its full latitude, insomuch that the predicate agrees to all the individuals comprehended under it if it denotes a proper species, and to all the several species and their individuals if it marks an idea of a higher order. The words *all, every, no, none*, &c. are the proper signs of this universality; and as they seldom fail to accompany general truths, so they form the most obvious criterion by which to distinguish them. "All animals have a power of beginning motion." This is an universal proposition, as we know from the word *all* prefixed to the subject *animals*, which denotes that it must be taken in its full extent. Hence the power of beginning motion may be affirmed of all the different species of animals.

Particular propositions.

3. A *particular* proposition has in like manner some general term for its subject, but with a mark of limitation added, to denote that the predicate agrees only to some of the individuals comprehended under a species, or to one

---

[1] See the preceding note, where it is demonstrated that the *terms* alone, and not the *ideas*, are in reality *general.* The term *man* is equally applicable to every individual of the human race; and therefore, what is affirmed or denied of *men* in general, is affirmed or denied of all the individuals, without regard to their discriminating qualities. *Some* is a definitive word (see GRAMMAR), which, prefixed to the word *man*, limits the signification of that *general term;* and therefore what is affirmed of *some men*, is affirmed only of *part* of the race, but that part itself is not ascertained.

or more of the species belonging to a genus, and not to the entire universal idea. Thus, "Some stones are heavier than iron;" "Some men have an uncommon share of prudence." In the latter of these propositions, the subject *some men* implies only a certain number of individuals, comprehended under a single species. In the former, where the subject is a genus which extends to a great variety of distinct classes, *some stones* may not only imply any number of particular stones, but also several whole species of stones, inasmuch as there may be not a few with the property there described. Hence we see that a proposition does not cease to be particular by the predicate's agreeing to a whole species, unless that species, singly and distinctly considered, forms also the subject of which we affirm or deny.

Singular propositions.

4. There is still one species of propositions which remains to be described, and which the more deserves our notice, as it is not yet agreed amongst logicians to which of the two classes mentioned above they ought to be referred; namely, *singular* propositions, or those where the subject is an individual. Of this nature are the following: "Sir Isaac Newton was the inventor of fluxions;" "This book contains many useful truths." What occasions some difficulty as to the proper rank of these propositions is, that the subject being taken according to the whole of its extension, they sometimes have the same effect in reasoning as universals. But if it be considered that they are in truth the most limited kind of particular propositions, and that no proposition can with any propriety be called universal but where the subject is some universal idea, we shall not find any difficulty in determining to which class they ought to be referred. When we say, "Some books contain useful truths," the proposition is particular, because the general term appears with a mark of restriction. If, therefore, we say, "This book contains useful truths," it is evident that the proposition must be still more particular, as the limitation implied in the word *this* is of a more confined nature than in the former case.

Fourfold division of propositions.

5. We perceive, therefore, that all propositions are either *affirmative* or *negative;* nor is it less evident that in both cases they may be *universal* or *particular*. Hence arises that celebrated fourfold division of them into *universal affirmative* and *universal negative*, *particular affirmative* and *particular negative*, which indeed comprehends all their varieties. The use of this method of distinguishing them will appear more fully afterwards, when we come to treat of reasoning and syllogism.

4. *Of Absolute and Conditional Propositions.*

Distinction of qualities.

1. The objects about which we are chiefly conversant in this world, are all of a nature very liable to change. What may be affirmed of them at one time, cannot often be affirmed at another; and one of the objects of our knowledge is to enable us to distinguish rightly these variations, and trace the reasons upon which they depend. For it is observable, that amidst all the vicissitudes of nature, some things remain constant and invariable; nor are even the changes to which we see others liable, effected, except in consequence of uniform and steady laws, which, when known, are sufficient to direct us in our judgments concerning them. Hence philosophers, in distinguishing the objects of our perception into various classes, have been very careful to state, that some properties belong so essentially to the general idea, as not to be separable from it except by destroying its very nature; whilst others are only accidental, and may be affirmed or denied of it in different circumstances. Thus solidity, a yellow colour, and a great weight, are considered as essential qualities of gold; but whether it shall exist as an uniform conjoined mass, is not alike necessary. We find that by a proper menstruum it may be reduced to a very fine powder, and that an intense heat will bring it into a state of fusion.

Of Judgm

Diversi in our n ner of j ing.

2. From this diversity in the several qualities of things arises a considerable difference as to the manner of our judging concerning them. For all such properties as are inseparable from objects when considered as belonging to any genus or species, are affirmed absolutely and without reserve of that general idea. Thus we say, "Gold is very weighty;" "A stone is hard;" "Animals have a power of self-motion." But in the case of mutual or accidental qualities, as they depend upon some other consideration distinct from the general idea, that must also be taken into the account, in order to form an accurate judgment. Should we affirm, for instance, of some stones, that they are very susceptible of a rolling motion, the proposition, whilst it remains in this general form, cannot with any advantage be introduced into our reasonings. An aptness to receive that mode of motion flows from the figure of the stone, which, as it may vary infinitely, so our judgment only becomes applicable and determinate, when the particular figure, of which volubility is a consequence, is also taken into the account. Let us then introduce this other consideration, and the proposition will run as follows: "Stones of a spherical form are easily put into a rolling motion." Here we see the condition upon which the predicate is affirmed, and therefore know in what particular cases the proposition may be applied.

Absolut and con ditional proposi tions.

3. This consideration of propositions respecting the manner in which the predicate is affirmed of the subject, gives rise to the division of them into *absolute* and *conditional*. *Absolute* propositions are those in which we affirm some property inseparable from the idea of the subject, and which therefore belongs to it in all possible cases; as, "God is infinitely wise;" "Virtue tends to the ultimate happiness of man." But where the predicate is not necessarily connected with the idea of the subject, unless upon some consideration distinct from that idea, there the proposition is called *conditional*. The reason of the name is taken from the supposition annexed, which is of the nature of a condition, and may be expressed as such, thus: "If a stone be exposed to the rays of the sun, it will contract some degree of heat;" "If a river run in a very declining channel, its rapidity will constantly increase."

Impor tance of this divi sion.

4. There is not any thing of greater importance in philosophy than a due attention to this division of propositions. If we be careful never to affirm things absolutely excepting where the ideas are inseparably conjoined, and if in our other judgments we distinctly mark the conditions which determine the predicate to belong to the subject, we shall be the less liable to mistake in applying general truths to the particular concerns of human life. It is owing to the exact observance of this rule that mathematicians have been so fortunate in their discoveries, and that what they demonstrate of magnitude in general may be applied with ease in all obvious occurrences.

5. The truth of it is, that particular propositions are only known to be true, when we can trace their connection with universals; and it is accordingly the great business of science to find out general truths which may be applied with safety in all obvious instances. Now the great advantage arising from determining with care the conditions upon which one idea may be affirmed or denied of another, is this; that thereby particular propositions really become universal, may be introduced with certainty into our reasonings, and serve as standards to conduct and regulate our judgments. To illustrate this by a familiar instance; if we say, "Some water acts very forcibly," the proposition is particular; and as the conditions on which this forcible action depends are not mentioned, it is as yet uncertain in what cases it may be applied. Let us then supply these conditions, and the proposition will run thus: "Water conveyed in sufficient quantity along a steep descent acts very

forcibly." Here we have an universal judgment, inasmuch as the predicate *forcible action* may be ascribed to all water under the circumstances mentioned. Nor is it less evident that the proposition in this new form is of easy application; and in fact we find that men do apply it in instances where the forcible action of water is required, as in corn-mills and many other works of art.

5. *Of Simple and Compound Propositions.*

1. Hitherto we have treated of propositions where only two ideas are compared together. These are in the general called *simple*, because, having but one subject and one predicate, they are the effect of a simple judgment, that admits of no subdivision. But if it so happens that several ideas offer themselves to our thoughts at once, by which we are led to affirm the same thing of different objects, or different things of the same object, then the propositions expressing these judgments are called *compound;* because they may be resolved into as many others as there are subjects or predicates in the whole complex determination on the mind. Thus, "God is infinitely wise and infinitely powerful." Here there are two predicates, *infinite wisdom*, and *infinite power*, both affirmed of the same subject; and accordingly the proposition may be resolved into two others, affirming these predicates severally. In like manner, in the proposition, "Neither kings nor people are exempt from death," the predicate is denied of both subjects, and may therefore be separated from them in distinct propositions. Nor is it less evident, that if a complex judgment consists of several subjects and predicates, it may be resolved into as many simple propositions as are the number of different ideas compared together. "Riches and honours are apt to elate the mind, and increase the number of our desires." In this judgment there are two subjects and two predicates, and it is at the same time apparent that it may be resolved into four distinct propositions. "Riches are apt to elate the mind;" "Riches are apt to increase the number of our desires." And so of "honours."

2. Logicians have divided these compound propositions into a great many different classes; but, in our opinion, not with a due regard to their proper definition. Thus, *conditionals, causals, relatives*, and others, are mentioned as so many distinct species of this kind, though in fact they are no more than simple propositions. To give an instance of a conditional; "If a stone be exposed to the rays of the sun, it will contract some degree of heat." Here we have but one subject and one predicate; for the complex expression, *a stone exposed to the rays of the sun*, constitutes the proper subject of this proposition, and is no more than one determinate idea. The same thing happens in causals. Thus, "Rehoboam was unhappy because he followed evil counsel." Here there is an appearance of two propositions arising from the complexity of the expression; but when we come to consider the matter more nearly, it is evident that we have but a single subject and predicate. "The pursuit of evil counsel brought misery upon Rehoboam." It is not enough, therefore, to render a proposition compound, that the subject and predicate are complex notions, requiring sometimes a whole sentence to express them; for in this case the comparison is still confined to two ideas, and constitutes what we call a simple judgment. But where there are several subjects or predicates, or both, as the affirmation or negation may be alike extended to them all, the proposition expressing such a judgment is truly a collection of as many simple ones as there are different ideas compared. Confining ourselves, therefore, to this more strict and just notion of compound propositions, they are all reducible to two kinds, viz. *copulatives* and *disjunctives*.

3. A *copulative* proposition is, where the subjects and predicates are so linked together that they may be all severally affirmed or denied one of another. Of this nature are the examples of compound propositions given above. "Riches and honours are apt to elate the mind, and increase the number of our desires;" "Neither kings nor people are exempt from death." In the first of these, the two predicates may be affirmed severally of each subject, whence we have four distinct propositions. The other furnishes an example of the negative kind, where the same predicate, being disjoined from both subjects, may be also denied of them in separate propositions.

Disjunctive propositions.

4. The other species of compound propositions are those called disjunctive; in which, comparing several predicates with the same subject, we affirm that one of them necessarily belongs to it, but leave the particular predicate undetermined. If any one, for example, says, "This world either exists of itself, or is the work of some all-wise and powerful cause," it is evident that one of the two predicates must belong to the world; but as the proposition determines not which, it is therefore of the kind we call *disjunctive.* Such too are the following: "The sun either moves round the earth, or is the centre about which the earth revolves;" "Friendship finds men equal, or makes them so." It is the nature of all propositions of this class, supposing them to be exact in point of form, that upon determining the particular predicate, the rest are of course to be removed; or if all the predicates but one are removed, that one necessarily takes effect, to the exclusion of the others. Thus, in the example given above, if we allow the world to be the work of some wise and powerful cause, we of course deny it to be self-existent; or if we deny it to be self-existent, we must necessarily admit that it was produced by some wise and powerful cause. Now this particular manner of linking the predicates together, so that the establishing of one displaces all the rest, or the excluding all but one necessarily establishes that one, cannot otherwise be effected than by means of *disjunctive* particles. And hence it is that propositions of this class take their names from these particles, which form so necessary a part of them, and indeed constitute their very nature considered as a distinct species.

6. *Of the Division of Propositions into Self-evident and Demonstrable.*

Propositions divided into self-evident and demonstrable.

1. When any proposition is offered to the view of the mind, if the terms in which it is expressed be understood, upon comparing the ideas together, the agreement or disagreement asserted will either be immediately perceived, or will be found to lie beyond the actual reach of the understanding. In the first case, the proposition is said to be *self-evident*, and admits not of any proof, because a bare attention to the ideas themselves produces full conviction and certainty; nor is it possible to call in any thing more evident by way of confirmation. But where the connection or repugnance comes not so readily under the inspection of the mind, we must have recourse to reasoning; and if by a clear series of proofs we can make out the truth proposed, insomuch that self-evidence shall accompany every step of the procedure, we are then able to demonstrate what we assert, and the proposition itself is said to be *demonstrable.* When we affirm, for instance, "That it is impossible for the same thing to be and not to be," whoever understands the terms made use of, perceives at the first glance the truth of what is asserted, nor can he by any efforts bring himself to believe the contrary. The proposition, therefore, is *self-evident*, and such that it is impossible by reasoning to make it plainer; because there is no truth more obvious or better known, from which it may be deduced as a consequence. But if we say, "This world had a beginning," the assertion is indeed equally true, but shines not forth with the same degree of evidence. We find great difficulty in con-

ceiving how the world could be made out of nothing, and are not brought to a free and full consent, until by reasoning we arrive at a clear view of the absurdity involved in the contrary supposition. Hence this proposition is of the kind we call *demonstrable*, inasmuch as its truth is not immediately perceived by the mind, but yet may be made clear by means of others more known and obvious, whence it follows as an unavoidable consequence.

Self-evident truths.

2. From what has been said, it appears that reasoning is employed only about demonstrable propositions, and that our intuitive and self-evident perceptions are the ultimate foundation upon which it rests.

3. Self-evident propositions furnish the first principles of reasoning; and it is certain, that if in our researches we employ only such principles as possess this character of self-evidence, and apply them according to the rules to be afterwards explained, we shall be in no danger of error in advancing from one discovery to another. For this we may appeal to the writings of the mathematicians, which being conducted by the express model here mentioned, furnish incontestable proof of the firmness and stability of human knowledge, when built upon so sure a foundation. For not only have the propositions of this science stood the test of ages, but they are found attended with that invincible evidence, which forces the assent of all who duly consider the proofs upon which they are established. Since the mathematicians are universally allowed to have hit upon the right method of arriving at unknown truths, since they have been the happiest in the choice as well as the application of their principles, it may not be amiss to explain here their method of stating self-evident propositions, and applying them to the purposes of demonstration.

Definition a help to clearness and evidence in knowledge.

4. First, then, it is to be observed, that they have been very careful in ascertaining their ideas, and fixing the signification of their terms. For this purpose they begin with *definitions*, in which the meaning of their words is so distinctly explained, that they cannot fail to excite in the mind of an attentive reader the very same ideas which are annexed to them by the writer. And indeed the clearness and irresistible evidence of mathematical knowledge is owing to nothing so much as this care in laying the foundation. Where the relation between any two ideas is accurately and justly traced, it will not be difficult for another to comprehend that relation, if in setting himself to discover it he brings the very same ideas into comparison. But if, on the contrary, he affixes to his words ideas different from those that were in the mind of him who first advanced the demonstration, it is evident, that as the same ideas are not compared, the same relation cannot subsist, insomuch that a proposition will be rejected as false, which, had the terms been rightly understood, must have appeared incontestably true. A square, for instance, is a figure bounded by four equal right lines, joined together at right angles. Here the nature of the angles constitutes a part of the idea no less than the equality of the sides; and many properties demonstrated of the square are deduced entirely from its being a rectangular figure. If therefore we suppose a man, who has formed a partial notion of a square, comprehending only the equality of its sides, without regard to the angles, reading some demonstration which implies also this latter consideration, it is plain that he would reject it as not universally true, inasmuch as it could not be applied where the sides were joined together at equal angles. For this last figure, answering still to his idea of a square, would be yet found without the property assigned to it in the proposition. But if he comes afterwards to correct his notion, and to render his idea complete, he will then readily admit the truth and justness of the demonstration.

Their use in mathematics.

5. We see, therefore, that nothing contributes so much to the improvement and certainty of human knowledge, as the having determinate ideas, and keeping them steady and invariable in all our discourses and reasonings concerning them. On this account it is that mathematicians, as has already been observed, always begin by defining their terms, and distinctly unfolding the notions which they are intended to express. Hence such as apply themselves to these studies have exactly the same views of things; and, bringing always the very same ideas into comparison, they readily discern the relations between them. It is likewise of importance, in every demonstration, to express the same *idea* invariably by the same word. From this practice mathematicians never deviate; and if it be necessary in *their* demonstrations, where the reader's comprehension is *aided* by a diagram, it is much more so in all reasonings concerning moral or intellectual truths, where the ideas cannot be represented by a diagram. The observation of this rule may sometimes be productive of ill-sounding periods; but when *truth* is the object, euphony ought to be disregarded.

Establis- ment of principle the seco step in m thematic knowled

6. When the mathematicians have taken this first step, and made known the ideas the relations of which they intend to investigate, their next care is, to lay down some self-evident truths, which may serve as a foundation for their future reasonings. And here indeed they proceed with remarkable circumspection, admitting no principles but such as flow immediately from their definitions, and necessarily force themselves upon every mind in any degree attentive to its ideas. Thus a *circle* is a figure formed by a right line moving round some fixed point in the same plane. The fixed point round which the line is supposed to move, and where one of its extremities terminates, is called the *centre* of the circle. The other extremity, which is conceived to be carried round until it returns to the point whence it first set out, describes a curve running into itself, which is termed the *circumference*. All right lines drawn from the centre to the circumference are called *radii*. From this definition geometricians derive the self-evident truth, "That the radii of the same circle are all equal to one another;" or rather, perhaps, it is part of, and involved in, the very definition.

Proposi- tions divi ed into sp culative and pract cal.

7. We may now observe, that in all propositions we either affirm or deny some property of the idea which constitutes the subject of our judgment, or we maintain that something may be done or effected. The first sort are called *speculative* propositions, as in the example mentioned above, "The radii of the same circle are all equal one to another." The others are called *practical*, for a reason too obvious to be mentioned; thus, "That a right line may be drawn from one point to another," is a practical proposition, inasmuch as it expresses that something may be done.

Mathem tical prin ciples, ho distin- guished.

8. From this twofold consideration of propositions arises the twofold division of mathematical principles into axioms and postulates. By an *axiom* is understood any self-evident speculative truth; such as, "That the whole is greater than its parts;" "That things equal to one and the same thing are equal to one another." But a self-evident practical proposition is what is denominated a *postulate*. Such are those of Euclid: "That a finite right line may be continued directly forwards;" "That a circle may be described about any centre with any distance." And here we have to observe, that as in an axiom the agreement or disagreement between the subject and predicate must come under the immediate inspection of the mind; so in a postulate, not only the possibility of the thing asserted must be evident at first view, but also the manner in which it may be effected. For where this manner is not of itself apparent, the proposition comes under the notion of the demonstrable kind, and is treated as such by geometrical writers. Thus, "To draw a right line from one point to another," is assumed by Euclid as a postulate, because the manner of doing it is so obvious, as to require no previous teaching. But then it is not equally evident how we are to construct an equilateral triangle. For this reason he advances it

as a demonstrable proposition, lays down rules for the exact performance, and at the same time proves, that if these rules are followed, the figure described will be an equilateral triangle.

9. This leads us to take notice, that as self-evident truths are distinguishable into different kinds, according as they are speculative or practical, so is it also with demonstrable propositions. A demonstrable speculative proposition is by mathematicians called a *theorem.* Such is the famous forty-seventh proposition of the first book of the Elements, known by the name of the *Pythagorean theorem*, from its supposed inventor Pythagoras, viz. "That in every right-angled triangle, the square described upon the side subtending the right angle is equal to the sum of the squares described upon the sides containing the right angle." On the other hand, a demonstrable practical proposition is called a *problem;* as where Euclid teaches us to describe a square upon a given right line.

10. It may not be amiss to add, that, besides the four kinds of propositions already mentioned, mathematicians have also a fifth, known by the name of *corollaries.* These are usually subjoined in theorems or problems, and differ from them only in this, that they flow from what is there demonstrated, in so obvious a manner as to discover their dependence upon the proposition whence they are deduced, almost as soon as proposed. Thus, Euclid, having demonstrated, "That in every right-lined triangle all the three angles taken together are equal to two right angles," adds by way of corollary, "That all the three angles of any one triangle taken together are equal to all the three angles of any other triangle taken together;" which is evident at first sight, because in all cases they are equal to two right angles, and things which are equal to one and the same thing are equal to one another.[1]

11. The scholia of mathematicians are indifferently annexed to definitions, propositions, or corollaries, and answer the same purposes as annotations upon a classic author. For in them occasion is taken to explain whatever may appear intricate and obscure in a train of reasoning; to answer objections; to teach the application and uses of propositions; to lay open the origin and history of the several discoveries which have been made in the science; and, in a word, to acquaint us with all such particulars as deserve to be known, whether considered as points of curiosity or of profit.

III.—OF REASONING.

1. *Of Reasoning in general, and the Parts of which it consists.*

Remote relations discovered by means of intermediate ideas.

It often happens, in comparing together ideas, that their agreement or disagreement cannot be discerned at first view, especially if they are of such a nature as not to admit of an exact application one to another.

When, for instance, we compare two figures of a different form, in order to judge of their equality or inequality, it is plain, that by barely considering the figures themselves, we cannot arrive at an exact determination, because, by reason of their disagreeing forms, it is impossible so to put them together that their several parts shall mutually coincide. Here, then, it becomes necessary to look out for some third idea which will admit of such an application as the case requires, wherein, if we succeed, all difficulties vanish, and the relation we are in quest of may be traced with ease. Thus, right-lined figures are all reduced to squares, by means of which we can measure their areas, and determine exactly their agreement or disagreement in point of magnitude.

This manner of arriving at truth termed reasoning.

2. But how can any third idea serve to discover a relation between two others? The answer is, by being compared severally with these others; for such a comparison enables us to discern how far the ideas with which this third is compared are connected or disjoined between themselves. In the example mentioned above, of two right-lined figures, if we compare each of them with some square whose area is known, and find the one exactly equal to it, and the other less by a square inch, we immediately conclude that the area of the first figure is a square inch greater than that of the second. This manner of determining the relation between any two ideas, by the intervention of some third one with which they may be compared, is that which we call *reasoning*, and is indeed the chief instrument by which we extend our discoveries and enlarge our knowledge. The great art consists in finding out such intermediate ideas as, when compared with others in the question, will furnish evident and known truths; because, as will afterwards appear, it is only by means of these that we arrive at the knowledge of what is hidden and remote.

The parts that constitute an act of reasoning and a syllogism.

3. Hence it appears that every act of reasoning necessarily includes three distinct judgments; two in which the ideas whose relation we want to discover are severally compared with the middle idea, and a third in which they are themselves connected or disjoined, according to the result of that comparison. Now, as in the second part of logic, our judgments, when put into words, were called propositions, so here in the third part the expressions of our reasonings are termed *syllogisms.* And hence it follows, that as every act of reasoning implies three several judgments, so every syllogism must include three distinct propositions. When reasoning is thus put into words, and appears in the form of a syllogism, the intermediate idea made use of to discover the agreement or disagreement we search for is called the *middle term*, and the two ideas themselves with which this third is compared are denominated the *extremes.*

---

[1] It is proper here to caution the reader against being led into any misconception as to the real nature of *axioms*, which, as above stated, have commonly been understood to mean "self-evident speculative truths." That they are "self-evident" is undeniable; but it is not so easy to see how they can be called "speculative truths," since in all cases where they predicate *equality* they are *identical propositions*, and, where they do not, they are mere *truisms*, if we may use such a term, or propositions of such a kind that to suppose the contrary would involve an obvious absurdity. When we say, That the whole is equal to all its parts put together, or, That things which are equal to the same thing are equal to one another, we merely express two identical propositions, or in effect just affirm that $a = a$, and $y = y$; affirmations which can add nothing either to the evidence or the truth of any demonstration. Such propositions amount only to a sort of *jeu de mots.* Besides, they are illogical, inasmuch as the "self-evident" truth which is predicated in the second is invariably assumed in the first branch of the proposition. The "whole" necessarily includes all its parts, and "things equal to one and the same thing" involve mutual equality. If we were to repeat the axiom, "That whatever is, is for an age, or for ages, we would not be in any respect wiser, or nearer to the discovery of any truth not self-evident, than we were before. Again, when we say, That the whole is greater than any of its parts, we merely affirm a truism, since the bare idea of a "whole" necessarily excludes that of the equality of any of its parts. It is, therefore, a mistake to suppose that axioms add any thing to the clearness or force of mathematical evidence. No conclusion whatever can be deduced from an identical proposition, in which the thing assumed is also the thing predicated. The whole fabric of geometry is built, not upon axioms, but upon *definitions*, expressing simple facts, as, for instance, the definition of a circle; and the real character of geometrical evidence consists in this, that it is founded, not upon identical propositions or truisms, but upon an appeal to observation, though of the simplest and most elementary kind. (A.)

Of Reasoning.

4. But as these things are best illustrated by examples, let us, for instance, set ourselves to inquire "Whether men be accountable for their actions." As the relation between the ideas of *man* and *accountableness* comes not within the immediate view of the mind, our first care must be to find out some third idea that will enable us the more easily to discover and trace it. A very small measure of reflection is sufficient to inform us, that no creature can be accountable for his actions unless we suppose him capable of distinguishing good from evil; that is, unless we suppose him possessed of reason. Nor is this alone sufficient. For what would it avail him to know good from evil actions if he had no freedom of choice, and could not avoid the one or pursue the other? Hence it becomes necessary to take in both considerations in the present case. It is at the same time equally apparent, that wherever there is the ability of distinguishing good from bad actions, and of pursuing the one and avoiding the other, there also a creature is accountable. We have then got a third idea, with which *accountableness* is inseparably connected, viz. *reason and liberty*, which are here to be considered as forming one complex conception. Let us now take this middle idea, and compare it with the other term in the question, viz. *man*, and we all know by experience that it may be affirmed of him. Having thus, by means of the intermediate idea, formed two several judgments, viz. *that man is possessed of reason and liberty*, and *that reason and liberty imply accountableness*, a third obviously and necessarily follows, viz. *that man is accountable for his actions.* Here then we have a complete act of reasoning, in which, according to what has been already observed, there are three distinct judgments; two which may be styled previous, inasmuch as they lead to the other, and arise from comparing the middle idea with the two ideas contained in the question; the third is a consequence of these previous acts, and flows from combining the extreme ideas between themselves. If now we put this reasoning into words, it exhibits what logicians term a syllogism, and, when proposed in due form, runs thus: "Every creature possessed of reason and liberty is accountable for his actions. Man is a creature possessed of reason and liberty: Therefore man is accountable for his actions."

Premises, conclusion, extremes middle term.

5. In this syllogism we may observe, that there are three several propositions expressing the three judgments implied in the act of reasoning, and so disposed as to represent distinctly what passes within the mind in tracing the more distant relations of its ideas. The first two propositions answer the two previous judgments in reasoning, and are called the *premises*, because they are placed before the other. The third is termed the *conclusion*, as being gained in consequence of what was asserted in the premises. We are also to remember that the terms expressing the two ideas the relations of which we inquire into, as *man* and *accountableness*, are in general called the *extremes;* and that the intermediate idea, by means of which the relation is traced, viz. *a creature possessed of reason and liberty*, takes the name of the *middle term.* Hence it follows, that by the *premises* of a syllogism we are always to understand the two propositions where the middle term is severally compared with the *extremes;* for these constitute the previous judgments, whence the truth we are in quest of is by reasoning deduced. The *conclusion* is that other proposition, in which the *extremes* themselves are joined or separated, agreeably to what appears upon the above comparison.

Of Reasoni

Major a minor term, m jor and nor prop sition.

6. The conclusion is made up of the extreme terms of the syllogism; and the extreme which serves as the predicate of the conclusion goes by the name of the *major term;* the other extreme, which makes the subject in the same proposition, is called the *minor term.* From this distinction of the extremes arises also a distinction between the premises, where these extremes are severally compared with the middle term. That proposition which compares the greater extreme, or the predicate of the conclusion, with the middle term, is called the *major proposition;* the other, in which the same middle term is compared with the subject of the conclusion or lesser extreme, is called the *minor proposition.* All this is obvious from the syllogism already stated, where the conclusion is, "Man is accountable for his actions." For here the predicate *accountable for his actions* being connected with the middle term in the first of the two premises, "Every creature possessed of reason and liberty is accountable for his actions," gives what we call the *major proposition.* In the second of the premises, "Man is a creature possessed of reason and liberty," we find the lesser extreme, or subject of the conclusion, viz. *man*, connected with the same middle term, whence it is known to be the *minor proposition.* When a syllogism is proposed in due form, the major proposition is always placed first, the minor next, and the conclusion last.

In a sing act of re soning, t premises must be i tuitive truths.

7. These things being premised, we may in general define reasoning to be an act or operation of the mind deducing some unknown proposition from other previous ones which are evident and known. These previous propositions, in a simple act of reasoning, are only two in number; and it is always required that they be of themselves apparent to the understanding, insomuch that we assent to and perceive the truth of them as soon as proposed. In the syllogism above given, the premises are supposed to be self-evident truths, otherwise the conclusion could not be inferred by a single act of reasoning. If, for instance, in the major, "Every creature possessed of reason and liberty is accountable for his actions," the connection between the subject and predicate could not be perceived by a bare attention to the ideas themselves, it is evident that this proposition would no less require a proof than the conclusion deduced from it. In this case a new middle term must be sought for to trace the connection here supposed; and this of course furnishes another syllogism, by which having established the proposition in question, we are then, and not before, at liberty to use it in any succeeding train of reasoning. And should it so happen, that in this second essay there still existed some previous proposition whose truth did not appear at first sight, we must then have recourse to a third syllogism in order to lay open that truth to the mind; because, as long as the premises remain uncertain, the conclusion built upon them must be so likewise. When, by conducting our thoughts in this manner, we at last arrive at some syllogism where the previous propositions are intuitive truths, the mind then rests in full security, as perceiving that the several conclusions it has passed through stand upon the immoveable foundation of self-evidence, and, when traced to their source, terminate in it.

Reasoning only a con catenation of syllo gisms.

8. We see, therefore, that in order to infer a conclusion by a single act of reasoning, the premises must be intuitive propositions. Where they are not, previous syllogisms are required; in which case reasoning becomes a complicated act, taking in a variety of successive steps. This frequently happens in tracing the more remote relation of our ideas, where, many middle terms being called in, the conclusion cannot be made out but in consequence of a series of syllogisms following one another in train. But although in this concatenation of propositions, those which form the premises of the last syllogism are often considerably removed from self-evidence, yet if we trace the reasoning backwards, we shall find them the conclusions of previous syllogisms, whose premises approach nearer and nearer to intuition in proportion as we advance, and are found at last to terminate in it. And if, after having thus unravelled a demonstration, we take it the contrary way,

and observe how the mind, setting out with intuitive perceptions, couples them together to form a conclusion; how, by introducing this conclusion into another syllogism, it still advances one step farther, and so proceeds, making every new discovery subservient to its future progress; we shall then perceive clearly that reasoning, in the highest sense of that faculty, is no more than an orderly combination of those simple acts which we have already so fully explained.

9. Thus we see, that reasoning, beginning with first principles, rises gradually from one judgment to another, and connects them in such manner that every stage of the progression brings intuitive certainty along with it. And now at length we may clearly understand the definition given above of this distinguishing faculty of the human mind. Reason, we have said, is the ability of deducing unknown truths from principles or propositions which are already known. This appears evident by the foregoing account, where we see that no proposition is admitted into a syllogism to serve as one of the previous judgments on which the conclusion rests, unless it be itself a known and established truth, the connection of which with self-evident principles has already been traced.

2. *Of the several kinds of Reasoning; and, first, of that by which we determine the Genera and Species of Things.*

All the aims of human reason may in the general be reduced to these two: First, to rank things under those universal ideas to which they truly belong; and, secondly, to ascribe to them their several attributes and properties in consequence of that distribution.

2. One great aim of human reason is to determine the genera and species of things. We have seen, in the first part of this treatise, how the mind proceeds in framing general ideas. We have also seen, in the second part, how, by means of these general ideas, we come by universal propositions. Now, as in these universal propositions we affirm some property of a genus or species, it is plain that we cannot apply this property to particular objects till we have first determined whether they are comprehended under that general idea of which the property is affirmed. Thus there are certain properties belonging to all *even* numbers, which nevertheless cannot be applied to any particular number, until we have first discovered it to be of the species expressed by that natural name. Hence reasoning begins with referring things to their several divisions and classes in the scale of our ideas; and as these divisions are all distinguished by particular names, we thereby learn to apply the terms expressing general conceptions to such particular objects as come under our immediate observation.

3. Now, in order to arrive at these conclusions, by which the several objects of perception are brought under general names, two things are manifestly necessary. First, that we should take a view of the idea itself, which is denoted by that general name, and carefully attend to the distinguishing marks which serve to characterize it. Secondly, that we should compare this idea with the object under consideration, observing diligently wherein they agree or differ. If the idea be found to correspond with the particular object, we then without hesitation apply the general name; but if no such correspondence intervene, the conclusion must necessarily take a contrary turn. Let us, for instance, take the number *eight*, and consider by what steps we are led to pronounce it an *even* number. First, then, we call to mind the idea signified by the expression *an even number*, viz. that it is a number divisible into two equal parts. We then compare this idea with the number *eight*, and finding them manifestly to agree, see at once the necessity of admitting the conclusion. These several judgments, therefore, transferred into language, and reduced to the form of a syllogism, appear thus: "Every number that may be divided into two equal parts is an *even* number: The number eight may be divided into two equal parts: Therefore the number *eight* is an *even* number."

Those steps always followed.

4. Here it may be observed, that where the general idea, to which particular objects are referred, is perfectly familiar to the mind, and frequently in view, this reference, and the application of the general name, seem to be made without any apparatus of reasoning. When we see a horse in the fields, or a dog in the street, we readily apply the name of the species; habit, and a familiar acquaintance with the general idea, suggesting it instantaneously to the mind. We are not however to imagine on this account that the understanding departs from the usual rules of just thinking. A frequent repetition of acts begets a habit; and habits are attended with a certain promptness of execution, which prevents our observing the several steps and gradations by which any course of action is accomplished. But in other instances, where we judge not by precontracted habits, as when the general idea is very complex, or less familiar to the mind, we always proceed according to the form of reasoning established above. A goldsmith, for instance, who is in doubt as to any piece of metal, whether it be of the species called *gold*, first examines its properties, and then, comparing them with the general idea signified by that name, if he find a perfect correspondence, no longer hesitates under what class of metals to rank it.

Importance of this branch of reasoning.

5. Nor let it be imagined that our researches here, because in appearance bounded to the imposing of general names upon particular objects, are therefore trivial and of little consequence. Some of the most considerable debates amongst mankind, and such too as nearly regard their lives, interest, and happiness, turn wholly upon this article. Is it not the chief employment of our several courts of judicature to determine, in particular instances, what is law, justice, and equity? Of what importance is it in many cases to decide aright whether an action shall be termed *murder* or *manslaughter?* We perceive then that no less than the lives and fortunes of men depend often upon these decisions. The reason is plain. Actions, when once referred to a general idea, draw after them all that may be affirmed of that idea; insomuch that the determining the species of actions is all one with determining what proportion of praise or dispraise, commendation or blame, ought to follow them. For as it is allowed that murder deserves death, by bringing any particular action under the head of murder, we of course decide the punishment due to it.

Exact observance of it practised by mathematicians.

6. But the great importance of this branch of reasoning, and the necessity of care and circumspection in referring particular objects to general ideas, is still further evident from the practice of the mathematicians. Every one who has read Euclid, knows that he frequently requires us to draw lines through certain points, and according to such and such directions; and that the figures thence resulting are often squares, parallelograms, or rectangles. Yet Euclid never supposes this from their bare appearance, but always demonstrates it upon the strictest principles of geometry. Nor is the method he takes in any thing different from that described above. Thus, for instance, having defined a square to be a figure bounded by four equal sides joined together at right angles, when such a figure arises in any construction previous to the demonstration of a proposition, he never calls it by that name until he has shown that its sides are equal, and all its angles right angles. Now this is apparently the same form of reasoning we have before exhibited in proving *eight* to be an even number.

Fixed invariable ideas.

7. Having thus explained the rules by which we are to conduct ourselves in ranking particular objects under general ideas, and shown their conformity to the practice and manner of the mathematicians, it remains only to observe, that the true way of rendering this part of knowledge both

easy and certain is, by habituating ourselves to clear and determinate ideas, and by keeping these steadily annexed to their respective names. For as all our aim is to apply general words aright, if these words stand for invariable ideas which are perfectly known to the mind, and can be readily distinguished upon occasion, there will be little danger of mistake or error in our reasonings. Let us suppose that, by examining any object, and carrying our attention successively from one part of it to another, we have made ourselves acquainted with the several particulars observable in it. If amongst these we find such as constitute some general idea, framed and settled beforehand by the understanding, and distinguished by a particular name, the resemblance thus known and perceived necessarily determines the species of the object, and thereby gives it a right to the name by which that species is called. Thus four equal sides, joined together at right angles, constitute the notion of a *square*. As this is a fixed and invariable idea, without which the general name cannot be applied, we never call any particular figure a *square* until it appears to have these several conditions; and, contrarily, wherever a figure is found to possess these conditions, it necessarily takes the name of a *square*. The same will be found to hold in all our other reasonings of this kind, where nothing can create any difficulty but the want of settled ideas. If, for instance, we have not determined within ourselves the precise notion denoted by the word *manslaughter*, it will be impossible for us to decide whether any particular action ought to bear that name; because, however nicely we may examine the action itself, yet, being strangers to the general idea with which it is to be compared, we are utterly unable to judge of their agreement or disagreement. But if we take care to remove this obstacle, and distinctly trace the two ideas under consideration, all difficulties vanish, and the resolution becomes both easy and certain.

8. Thus we see of what importance it is towards the improvement and certainty of human knowledge, that we should accustom ourselves to clear and determinate ideas, and to a steady application of words.

3. *Of Reasoning, as it regards the Powers and Properties of Things, and the Relations of our general Ideas.*

Distinction of reasoning, as it regards the sciences, and common life.

1. We now come to the second great end which men have in view in their reasonings; namely, the discovering and ascribing to things their several attributes and properties. And here it will be necessary to distinguish between reasoning, as it regards the sciences, and as it concerns common life. In the sciences, our reason is employed chiefly about universal truths, because by these alone are the bounds of human knowledge enlarged. Hence the division of things into various classes, called otherwise *genera* and *species*. For these universal ideas being set up as the representatives of many particular things, whatever is affirmed of them may be also affirmed of all the individuals to which they belong. *Murder*, for instance, is a general idea, representing a certain species of human actions. Reason tells us that the punishment due to it is *death*. Hence every particular action, coming under the notion of *murder*, has the punishment of *death* allotted to it. Here then we apply the general truth to some obvious instance, and this is what properly constitutes the reasoning of common life; for men, in their ordinary transactions and intercourse with one another, have, for the most part, to do only with particular objects. Our friends and relations, their characters and behaviour, the constitution of the several bodies that surround us, and the uses to which they may be applied, are what chiefly engage our attention. In all these, we reason about particular things; and the whole result of our reasoning is, the applying the general truths of the sciences in the ordinary transactions of human life. When we see a viper, we avoid it. Wherever we have occasion for the forcible action of water to move a body which makes considerable resistance, we take care to convey it in such a manner that it shall fall upon the object with impetuosity. Now all this happens in consequence of our familiar and ready application of these two general truths: "The bite of a viper is mortal;" "Water falling upon any body with impetus, acts very forcibly towards setting it in motion." In like manner, if we set ourselves to consider any particular character, in order to determine the share of praise or dispraise which belongs to it, our great concern is to ascertain exactly the proportion of virtue and vice. The reason is obvious. A just determination, in all cases of this kind, depends entirely upon an application of these general maxims of morality: "Virtuous actions deserve praise;" "Vicious actions deserve blame."

Steps i the reasoning commo life.

2. Hence it appears that reasoning, as it regards common life, is no more than the ascribing the general properties of things to those several objects with which we are more immediately concerned, according as they are found to be of that particular division or class to which the properties belong. The steps, then, by which we proceed, are manifestly these. First, we refer the object under consideration to some general idea or class of things. We then recollect the several attributes of that general idea. And, lastly, we ascribe all those attributes to the actual object. Thus, in considering the character of Sempronius, if we find it to be of the kind called *virtuous*, when we at the same time reflect that a virtuous character is deserving of esteem, it naturally and obviously follows that Sempronius is an estimable man. These thoughts put into a *syllogism*, in order to exhibit the form of reasoning here required, run thus: "Every virtuous man is worthy of esteem. Sempronius is a virtuous man: Therefore Sempronius is worthy of esteem."

Connection anc dependence o the two branche of reasoning.

3. By this *syllogism* it appears, that before we affirm anything of a particular object, that object must be referred to some general idea. Sempronius is pronounced worthy of esteem only in consequence of his being a virtuous man, or coming under that general notion. Hence we see the necessary connection of the various parts of reasoning, and the dependence which they have one upon another. The determining the genera and the species of things is, as we have said, one exercise of human reason; and here we find that this exercise is the first in order, and previous to the other, which consists in ascribing to them their powers, properties, and relations. But when we have taken this previous step, and brought particular objects under general names, as the properties we ascribe to them are no other than those of the general idea, it is plain that, in order to a successful progress in this part of knowledge, we must thoroughly acquaint ourselves with the several relations and attributes of these our general ideas. When this is done, the other part will be easy, and require scarcely any labour or thought, being no more than an application of the general form of reasoning represented in the foregoing syllogism. Now, as it has already been sufficiently shown how we are to proceed in determining the genera and species of things, which, as we have stated, is the previous step to this second branch of human knowledge, all that is further wanting towards a due explanation of it is, to offer some considerations as to the manner of investigating the general relations of our ideas. This is the highest exercise of the powers of the understanding, and that by means of which we arrive at the discovery of universal truths; insomuch that our deductions in this way constitute that particular species of reasoning which, we have before said, regards principally the sciences.

4. But, that we may conduct our thoughts with some degree of order and method, we shall begin with observing,

that the relations of our general ideas are of two kinds; either such as immediately discover themselves, upon comparing the ideas one with another; or such as, being more remote and distant, require art and contrivance to bring them into view. The relations of the first kind furnish us with intuitive and self-evident truths. Those of the second are traced by reasoning, and a due application of intermediate ideas. It is of the latter kind that we are to speak here, having despatched what was necessary with regard to the other in the second part. As, therefore, in tracing the more distant relations of things, we must always have recourse to intervening ideas, and are more or less successful in our researches, according to our acquaintance with these ideas, and ability in applying them; so it is evident that, to make a good reasoner, two things are principally required: *First,* An extensive knowledge of those intermediate ideas, by means of which things may be compared one with another; and, *secondly,* The skill and talent of applying them happily in all particular instances which come under consideration.

5. In order to our successful progress in reasoning, we must have an extensive knowledge of those intermediate ideas by means of which things may be compared one with another. For as it is not every idea that will answer the purpose of our inquiries, but only such as are peculiarly related to the objects about which we reason, so as, by a comparison with them, to furnish evident and known truths, nothing is more apparent than that, the greater variety of conceptions we can call into view, the more likely are we to find some amongst them which will help us to the truths here required. And, indeed, it is found to hold in experience, that in proportion as we enlarge our views of things, and grow acquainted with a multitude of different objects, the reasoning faculty gathers strength; for, by extending our sphere of knowledge, the mind acquires a certain force and penetration, as being accustomed to examine the several appearances of its ideas, and observe what light they throw upon one another.

6. This is the reason why, in order to excel remarkably in any one branch of learning, it is necessary to have at least a general acquaintance with the whole circle of the arts and sciences. The truth is, that all the various divisions of human knowledge are very nearly related amongst themselves, and, in innumerable instances, serve to illustrate and set off one another. And although it is not to be denied that, by an obstinate application to one branch of study, a man may make considerable progress, and acquire some degree of eminence in it, yet his views will always be narrow and contracted, and he will want that masterly discernment which not only enables us to pursue our discoveries with ease, but also, in laying them open to others, to spread a certain brightness around them. But when our reasoning regards a particular science, it is further necessary that we should more nearly acquaint ourselves with whatever relates to that science. A general knowledge is a good preparation, and enables us to proceed with ease and expedition in whatever branch of learning we apply to. But then, in the minute and intricate questions of any science, we are by no means qualified to reason with advantage until we have perfectly mastered the science to which they belong.

7. We come now to the second thing required in order to a successful progress in reasoning; namely, the skill and talent of applying intermediate ideas happily in all particular instances that come under consideration. And here rules and precepts are of little service. Use and experience are the best instructors. For, however logicians may boast of being able to form perfect reasoners by book and rule, we find by experience that the study of their precepts does not always add any great degree of strength to the understanding. In short, it is the habit alone of reasoning that makes a reasoner; and therefore the true way to acquire this talent is, by being much conversant in those sciences where the art of reasoning requires to be exercised in the greatest perfection. Hence it was that the ancients, who so well understood the manner of forming the mind, always began with *mathematics* as the foundation of their philosophical studies. In this pursuit the understanding is by degrees habituated to truth, it contracts insensibly a certain fondness for it, and learns never to yield its assent to any proposition but where the evidence is sufficient to produce full conviction. For this reason Plato has called mathematical demonstrations the *cathartics* or purgatives of the soul, as being the proper means of cleansing it from error, and restoring that natural exercise of its faculties in which just thinking consists.

Value of mathematical demonstrations.

8. If, therefore, we would form our minds to a habit of reasoning closely and in train, we cannot take any more certain method than that of exercising ourselves in mathematical demonstrations, so as to contract a kind of familiarity with them. Not that we look upon it as necessary that all men should be deep mathematicians; but that, having mastered the way of reasoning which that study necessarily brings the mind to, they may be able to transfer it to other parts of knowledge, as they shall afterwards have occasion.

Value of authors distinguished for strength and justness of reasoning.

9. But though the study of mathematics be of all others the most useful to form the mind, and to give it an early relish for truth, yet other parts of philosophy ought not to be neglected. For there also we meet with many opportunities of exercising the powers of the understanding; and the variety of subjects naturally leads us to observe all those different turns of thinking which are peculiarly adapted to the several ideas we examine, and the truth we search after. A mind thus trained acquires a certain mastery over its own thoughts, insomuch that it can arrange and model them at pleasure, and call such into view as best suit its actual designs. Now in this consists the whole art of reasoning; from amongst a great variety of different ideas to single out those which are most proper for the business in hand, and to lay them together in such order, that from plain and easy beginnings, by gentle degrees, and a continued train of evident truths, we may be insensibly led on to such discoveries as at our first setting out would appear beyond the reach of human understanding. For this purpose, besides the study of mathematics already recommended, we should apply ourselves diligently to the reading of such authors as have distinguished themselves for strength of reasoning, and a just and accurate manner of thinking; for it is observable, that a mind exercised and seasoned to truth seldom rests satisfied with the bare contemplation of the arguments offered by others, but will be frequently essaying its own strength, and pursuing its discoveries upon the plan which it is most accustomed to. Thus we insensibly contract a habit of tracing truth from one stage to another, and of investigating those general relations and properties which we afterwards ascribe to particular things, according as we find them comprehended under the abstract ideas to which the properties belong.

4. *Of the Forms of Syllogisms.*

Figures of syllogisms.

1. Hitherto we have contented ourselves with giving a general notion of syllogisms, and of the parts of which they consist. It is now time to enter a little more particularly into the subject, to examine their various forms, and to lay down the rules of argumentation proper to each. In the syllogisms mentioned in the foregoing chapters, we may observe, that the *middle term* is the subject of the *major* proposition, and the predicate of the *minor*. This disposition, though the most natural and obvious, is not, however, necessary, as it frequently happens that the middle

B is b
A is B
∴ A is b

term is the subject in both the premises, or the predicate in both; and sometimes, directly contrary to its disposition in the foregoing chapters, it is the predicate in the major, and the subject in the minor. Hence the distinction of syllogisms into various kinds, called *figures* by logicians; for figure, according to their use of the word, is nothing else but the order and disposition of the middle term in any syllogism. And as this disposition is, as we have shown, fourfold, so the figures of syllogisms thence arising are four in number. When the middle term is the subject of the major proposition, and the predicate of the minor, we have what is called the *first figure;* as, "No work of God is bad: The natural passions and appetites of men are the work of God: Therefore none of them is bad." If, on the other hand, it is the predicate of both the premises, the syllogism is said to be the *second figure*; as, "Whatever is bad is not the work of God: All the natural passions and appetites of men are the work of God: Therefore the natural passions and appetites of men are not bad." Again, in the *third figure*, the middle term is the subject of the two premises: as, "All Africans are black: All Africans are men: Therefore some men are black." And, lastly, by making it the predicate of the major, and subject of the minor, we obtain syllogisms in the *fourth figure;* as, "The only Being who ought to be worshipped is the Creator and Governor of the world: The Creator and Governor of the world is God: Therefore God is the only Being who ought to be worshipped."

Moods of syllogisms.

2. But, besides this fourfold distinction of syllogisms, there is also a further subdivision of them in every figure, arising from the *quantity* and *quality*, as they are called, of the propositions. By quantity we mean the consideration of propositions, as universal or particular; by quality, as affirmative or negative.

Now as, in all the several dispositions of the middle term, the propositions of which a syllogism consists may be either universal or particular, affirmative or negative, the due determination of these, and the putting them together as the laws of argumentation require, constitute what logicians call the *moods* of syllogisms. Of these moods there is a determinate number to every figure, including all the possible ways in which propositions differing in quantity or quality can be combined, according to any disposition of the middle term, in order to arrive at a just conclusion.

The first figure has only four legitimate moods. The major proposition in this figure must be universal, and the minor affirmative; and it has this property, that it yields conclusions of all kinds, affirmative and negative, universal and particular.

The second figure has also four legitimate moods. Its major proposition must be universal, and one of the premises must be negative. It yields conclusions both universal and particular, but all negative.

The third figure has six legitimate moods. Its minor must always be affirmative; and it yields conclusions both affirmative and negative, but all particular. These are all the figures which were admitted by the inventor of syllogisms, and of which, so far as we know, the number of legitimate moods has been ascertained, and severally demonstrated. In *every figure* it will be found upon trial that there are *sixty-four* different moods of syllogism; and he who thinks it worth while to construct so many in the *fourth* figure, always remembering that the *middle term* in each must be the *predicate* of the *major* and the *subject* of the *minor* proposition, will easily discern what number of these moods are *legitimate*, and evolve true conclusions.

Besides the rules which are proper to each figure, Aristotle has given some that are common to all, by which the legitimacy of syllogisms may be tried. These may be reduced to five, viz. 1. There must be only *three terms* in a syllogism; and as each term occurs in two of the propositions, it must be precisely the *same in both;* for if it be *not*, the syllogism is said to have *four terms*, which makes a *vicious* syllogism. 2. The *middle term* must be taken *universally* in *one* of the premises. 3. Both premises must *not be particular* propositions, nor both *negative.* 4. The *conclusion* must be *particular*, if *either* of the *premises* be *particular;* and *negative*, if *either* of the *premises* be *negative.* 5. No term can be taken *universally* in the *conclusion*, if it be *not* taken *universally* in the *premises.* For understanding the *second* and *fifth* of these rules, it is necessary to observe, that a term is said to be taken *universally*, not only when it is the *subject* of a *universal* proposition, but also when it is the *predicate* of a *negative* proposition; and, on the other hand, a term is said to be taken *particularly*, when it is either the *subject* of a *particular* or the *predicate* of an *affirmative* proposition.

Foundation of t other di sion of s logisms.

3. The division of syllogisms according to moods and figures respects those especially which are known by the name of plain simple syllogisms; that is, which are limited to three propositions, all of them simple, and where the extremes and middle term are connected, according to the rules above laid down. But as the mind is not tied down to any one precise form of reasoning, but sometimes makes use of more, sometimes of fewer premises, and often employs compound and conditional propositions, it may not be amiss to take notice of the different forms derived from this source, and explain the rules by which the mind conducts itself in the use of them.

Conditio syllogism

4. When in any syllogism the major is a conditional proposition, the syllogism itself is termed *conditional.* Thus: "If there be a God, he ought to be worshipped: But there is a God: Therefore he ought to be worshipped." In this example the major or first proposition is, we see, conditional, and therefore the syllogism itself is also of the kind called conditional. And here we must observe, that all conditional propositions are composed of two distinct parts; one expressing the condition upon which the predicate agrees or disagrees with the subject, as in this now before us, *If there be a God;* and the other joining or disjoining the said predicate and subject, as here, *he ought to be worshipped.* The first of these parts, or that which implies the condition, is called the *antecedent;* the second, where we join or disjoin the predicate and subject, receives the name of the *consequent.*

Ground relation i condition syllogism

5. In all propositions of this kind, supposing them to be exact in point of form, the relation between the antecedent and consequent must ever be true and real; that is, the antecedent must always contain some certain and genuine condition, which necessarily implies the consequent; for otherwise the proposition itself will be false, and therefore ought not to be admitted into our reasonings. Hence it follows, that when any conditional proposition is assumed, if we admit the antecedent of that proposition, we must at the same time necessarily admit the consequent; but if we reject the consequent, we are in like manner bound to reject the antecedent. For as the antecedent always expresses some condition which necessarily implies the truth of the consequent, by admitting the antecedent, we allow of that condition, and therefore ought also to admit the consequent. In like manner, if it appear that the consequent ought to be rejected, the antecedent must evidently be so too; because, as has just been demonstrated, the admission of the antecedent would necessarily imply the admission likewise of the consequent.

Two moods of condition syllogism

6. There are two ways of arguing in *hypothetical* syllogisms, which lead to a certain and unavoidable conclusion; for, as the major is always a conditional proposition, consisting of an antecedent and a consequent, if the

minor admit the antecedent, it is plain that the conclusion must admit the consequent. This is called arguing from the admission of the antecedent to the admission of the consequent, and constitutes that mood or species of hypothetical syllogisms which is distinguished in the schools by the name of the *modus ponens*, inasmuch as by it the whole conditional proposition, both antecedent and consequent, is established. Thus: "If God is infinitely wise, and acts with perfect freedom, he does nothing but what is best: But God is infinitely wise, and acts with perfect freedom: Therefore he does nothing but what is best."

Here we see that the antecedent or first part of the conditional proposition is established in the minor, and the consequent or second part in the conclusion; whence the syllogism itself is an example of the *modus ponens*. But if, on the contrary, we suppose that the minor rejects the consequent, then it is apparent that the conclusion must also reject the antecedent. In this case we are said to argue from the removal of the consequent to the removal of the antecedent, and the particular mood or species of syllogisms thence arising is called by logicians the *modus tollens*, because in it both antecedent and consequent are rejected or taken away. This will appear by the following example: "If God were not a Being of infinite goodness, neither would he consult the happiness of his creatures: But God does consult the happiness of his creatures: Therefore he is a Being of infinite goodness."

7. These two species include the whole class of conditional syllogisms, and all the possible ways of arguing which lead to a legitimate conclusion; because we cannot here proceed by a contrary process of reasoning, that is, from the removal of the antecedent to the removal of the consequent, or from the establishing of the consequent to the establishing of the antecedent. For, although the antecedent always expresses some real condition, which, once admitted, necessarily implies the consequent, yet it does not follow that there is therefore no other condition; and if so, then, after removing the antecedent, the consequent may still hold, because of some other determination which infers it. When we say, "If a stone be exposed some time to the rays of the sun, it will contract a certain degree of heat," the proposition is certainly true; and, admitting the antecedent, we must also admit the consequent. But as there are various other ways by which a stone may become heated, it will not follow, from the ceasing of the before-mentioned condition, that therefore the consequent cannot take place. In other words, we cannot argue, "But the stone has not been exposed to the rays of the sun; therefore neither has it any degree of heat;" inasmuch as there are a great many other ways by which heat might have been communicated to it. And if we cannot argue from the removal of the antecedent to the removal of the consequent, no more can we argue from the admission of the consequent to the admission of the antecedent; because, as the consequent may flow from a great variety of different suppositions, the allowing of it does not determine the precise supposition, but only that some one of them must take place. Thus, in the foregoing proposition, "If a stone be exposed some time to the rays of the sun, it will contract a certain degree of heat;" admitting the consequent, viz. *that it has contracted a certain degree of heat*, we are not therefore bound to admit the antecedent, *that it has been some time exposed to the rays of the sun*, because there are many other sources whence that heat may have proceeded. These two ways of arguing, therefore, hold not in conditional syllogisms.

8. As from the major being a conditional proposition, we obtain the species of conditional syllogisms; so, where it is a disjunctive proposition, the syllogism to which it belongs is also called *disjunctive*, as in the following example: "The world is either self-existent, or the work of some finite, or of some infinite Being: But it is not self-existent, nor the work of a finite Being: Therefore it is the work of an infinite Being."

Manner of arguing disjunctive syllogisms.

Now, a disjunctive proposition is that where, of several predicates, we affirm one necessarily to belong to the subject, to the exclusion of all the rest, but leave that particular one undetermined. Hence it follows, that as soon as we determine the particular predicate, all the rest are of course to be rejected; or if we reject all the predicates but one, that one necessarily becomes effectual. When, therefore, in a disjunctive syllogism, the several predicates are enumerated in the major, if the minor establishes any one of these predicates, the conclusion ought to remove all the rest; or if, in the minor, all the predicates but one be removed, the conclusion must necessarily establish that one. Thus, in the disjunctive syllogism given above, the major affirms one of the three predicates to belong to the world, viz. *self-existence*, or that it is *the work of a finite*, or that it is *the work of an infinite Being*. Two of these predicates are removed in the minor, viz. *self-existence*, and *the work of a finite being*. Hence the conclusion necessarily ascribes to it the third predicate, and affirms that it is *the work of an infinite Being*. If now we give the syllogism another turn, insomuch that the minor may establish one of the predicates, by affirming the earth to be *the production of an infinite Being*, then the conclusion must remove the other two, asserting it to be neither *self-existent*, nor *the work of a finite Being*. These are the forms of reasoning in such species of syllogisms, the justness of which appears at first sight; and that there can be no other, is evident from the very nature of a disjunctive proposition.

Imperfect or mutilated syllogisms.

9. In the several kinds of syllogisms hitherto mentioned, we may observe that the parts are complete; that is, the three propositions of which they consist are represented in form. But it often happens that some one of the premises is not only an evident truth, but also familiar and in the minds of all men, in which case it is usually omitted, whereby we have an imperfect syllogism, which seems to be made up of only two propositions. Should we, for instance, argue in this manner: "Every man is mortal: Therefore every king is mortal:" the syllogism appears to be imperfect, as consisting but of two propositions. Yet it is really complete; only the minor [*every king is a man*] is omitted, and left to the reader to supply, as being a proposition so familiar and evident that it cannot escape him.

Enthymemes.

10. These seemingly imperfect syllogisms are called *enthymemes*,[1] and occur very frequently in reasoning, especially where it forms a part of common conversation. Nay, there is a particular elegance in them, because, not displaying the argument in all its parts, they leave somewhat to the exercise and invention of the mind. By this means we are put upon exerting ourselves, and even seem to share in the discovery of what is proposed to us. Now this is the great secret of fine writing, so to frame and put together our thoughts as to give full play to the reader's imagination, and draw him insensibly into our very views and course of reasoning. This gives a pleasure not unlike to that which the author himself feels in composing. Besides, it shortens discourse, and adds a certain force and liveliness to our arguments, when the words in which they are conveyed favour the natural quickness of the mind in

---

[1] Respecting the prevalent mistake relative to the *Enthymeme*, and Aristotle's doctrine concerning it, see *Edinburgh Review*, vol. lvii. p. 221, et seq.

its operations, and a single expression is left to exhibit a whole train of thoughts.

Ground of reasoning in immediate consequences.

11. But there is another species of reasoning with two propositions, which seems to be complete in itself, and where we admit the conclusion without supposing any tacit or suppressed judgment in the mind, from which it follows syllogistically. This happens between propositions where the connection is such that the admission of the one necessarily and at the first sight implies the admission also of the other; for if it so happens that the proposition upon which the other depends is self-evident, we content ourselves with barely affirming it, and infer the other by a direct conclusion. Thus, by admitting an universal proposition, we are forced also to admit of all the particular propositions comprehended under it, this being the very condition which constitutes a proposition universal. If then that universal proposition chance to be self-evident, the particular ones follow of course, without any further train of reasoning. Whoever allows, for instance, *that things equal to one and the same thing are equal to one another*, must at the same time allow, *that two triangles, each equal to a square whose side is three inches, are also equal between themselves*. This argument, therefore, "Things equal to one and the same thing, are equal to one another: Therefore these two triangles, each equal to the square of a line of three inches, are equal between themselves," is complete in its kind, and contains all that is necessary towards a just and legitimate conclusion. For the first or universal proposition is self-evident, and therefore requires no further proof. And as the truth of the particular is inseparably connected with that of the universal, it follows from it by an obvious and unavoidable consequence.

All reducible to syllogisms of one form or another.

12. Now, in all cases of this kind, where propositions are deduced one from another, on account of a known and evident connection, we are said to reason by immediate consequence. Such a coherence of propositions, manifest at first sight, and forcing itself upon the mind, frequently occurs in reasoning. Logicians have explained at some length the several propositions in which it takes place, and allow of all immediate consequences which follow in conformity to them. It is however observable, that these arguments, though seemingly complete, because the conclusion follows necessarily from the single proposition which goes before, may yet be considered as real enthymemes, whose major, which is a conditional proposition, is wanting. The syllogism but just mentioned, when represented according to this view, will run as follows: "If things equal to one and the same thing are equal to one another, these two triangles, each equal to a square whose side is three inches, are also equal between themselves. But things equal to one and the same thing, are equal to one another: Therefore also these triangles, &c. are equal between themselves."

This observation will be found to hold in all immediate consequences whatsoever, insomuch that they are in fact no more than the enthymemes of hypothetical syllogisms. But then it is particular to them, that the ground on which the conclusion rests, namely, its coherence with the minor, is of itself apparent, and observed to flow immediately from the rules and reasons of logic.

A sorites of plain simple syllogisms.

13. The next species of reasoning we shall take notice of here is what is commonly known by the name of a *sorites*. This is a way of arguing, in which a great number of propositions are so linked together that the predicate of one becomes continually the subject of the next following, until at last a conclusion is formed, by bringing together the subject of the first proposition, and the predicate of the last. Of this kind is the following argument: "God is omnipotent: An omnipotent Being can do every thing that is possible: He that can do every thing that is possible, can do whatever involves not a contradiction: Therefore God can do whatever involves not a contradiction."

This particular combination of propositions may be continued to any length we please, without in the least weakening the ground upon which the conclusion rests. The reason is, because the sorites itself may be resolved into as many simple syllogisms as there are middle terms in it; and this is found universally to hold, That when such a resolution is made, and the syllogisms are placed in train, the conclusion of the last in the series is also the conclusion of the sorites. This kind of argument, therefore, as it serves to unite several syllogisms into one, must stand upon the same foundation with the syllogisms of which it consists, and is, indeed, properly speaking, no other than a compendious way of reasoning syllogistically.

A sorites of hypothetical syllogism

14. What is here said of plain simple propositions may be as well applied to those that are conditional; that is, any number of them may be so joined together in a series, that the consequent of one shall become continually the antecedent of the next following; in which case, by establishing the antecedent of the first proposition, we also establish the consequent of the last, or by removing the last consequent, remove also the first antecedent. This way of reasoning is exemplified in the following argument: "If we love any person, all emotions of hatred towards him cease: If all emotions of hatred towards a person cease, we cannot rejoice in his misfortunes: If we rejoice not in his misfortunes, we certainly wish him no injury: Therefore, if we love a person, we wish him no injury." It is evident that this sorites, as well as the last, may be resolved into a series of distinct syllogisms, with only this difference, that here the syllogisms are all conditional.

Ground o argumentation in dilemma.

15. The last species of syllogism which we shall take notice of under this head is that commonly distinguished by the name of a *dilemma*. A dilemma is an argument by which we endeavour to prove the absurdity or falsehood of some assertion. In order to this, we assume a conditional proposition, the antecedent of which is the assertion to be disproved, and the consequent a disjunctive proposition, enumerating all the possible suppositions upon which that assertion can take place. If then it appears, that all these several suppositions ought to be rejected, it is plain that the antecedent or assertion itself must be so too. When therefore such a proposition as that before mentioned is made the major of any syllogism, if the minor rejects all the suppositions contained in the consequent, it follows necessarily that the conclusion ought to reject the antecedent, which, as we have said, is the very assertion to be disproved. This particular way of arguing is that which logicians call a *dilemma;* and from the account here given of it, it appears that we may generally define it to be a hypothetical syllogism, where the consequent of the major is a disjunctive proposition, which is wholly taken away or removed in the minor. Of this kind is the following: "If God did not create the world perfect in its kind, it must either proceed from want of inclination or from want of power: But it could not proceed either from want of inclination or from want of power: Therefore he created the world perfect in its kind: Or, which is the same thing, It is absurd to say that he did not create the world perfect in its kind."

Universal description.

16. The nature, then, of a dilemma is universally this: The major is a conditional proposition, whose consequent contains all the several suppositions upon which the antecedent can take place. As therefore these suppositions are wholly removed in the minor, it is evident that the antecedent must be so too, insomuch that we here always argue from the removal of the consequent to the removal of the antecedent; that is, a dilemma is an argument in the *modus tollens* of hypothetical syllogisms, as logicians express it. Hence it is plain, that if the antecedent of

the major be an affirmative proposition, the conclusion of the dilemma will be negative; but if it be a negative proposition, the conclusion will be affirmative.

5. *Of Induction.*[1]

1. All reasoning is ultimately resolvable into first truths, which are either self-evident or taken for granted; and the first truths of syllogistic reasonings are *general* propositions. But, except in the mathematics, and such other sciences as, being conversant about mere ideas, have no immediate relation to things without the mind, we cannot assume as truths propositions which are general. The mathematician, indeed, may be considered as taking his ideas from the beginning in their *general* form. Every *proposition* composed of such ideas is therefore general; and those which are theoretical are reducible to two parts or *terms*, a *predicate* and a *subject*, with a *copula* generally affirmative. If the agreement or the relation between the two terms be not immediate and self-evident, he has recourse to an *axiom*, which is a proposition still *more general*, and which supplies him with a third or *middle term*. This he compares, first with the *predicate*, and then with the *subject*, or *vice versa*. These two comparisons, when drawn out in form, constitute two propositions, which are called the *premises;* and if they happen to be *immediate* and *self-evident*, the *conclusion*, consisting of the terms of the question proposed, is said to be demonstrated. This method of reasoning is conducted exactly in the syllogistic form explained in the preceding chapter.

2. But in sciences which treat of things external to the mind, we cannot assume as *first principles* the most general propositions, and from them infer others less and less general, till we descend to particulars. The reason is obvious. Every thing in the universe, whether of mind or body, presents itself to our observation in its individual state; so that *perception* and *judgment* employed in the investigation of truth, whether *physical, metaphysical, moral,* or *historical*, have in the first place to deal with *particulars.* With these reason begins, or should begin, its operations. It observes, tries, canvasses, examines, and compares them together, and judges of them by some of those native evidences and original lights which, as they are the first and indispensable inlets of knowledge to the mind, so they have been called the *primary principles of truth.* See METAPHYSICS.

3. By such acts of observation and judgment, diligently practised and frequently repeated, upon many *individuals* of the same class or of a similar nature, observing their agreements, marking their differences however minute, and rejecting all instances which, however similar in appearance, are not in effect the same, REASON, with much labour and attention, extracts some *general laws* respecting the powers, properties, qualities, actions, passions, virtues, and relations of *real things.* This is no hasty, premature, notional abstraction of the mind, by which images and ideas are formed which have no archetypes in nature; it is a rational, operative, experimental process, instituted and executed upon the constitution of beings, which in part compose the universe. By this process REASON advances from *particulars* to *generals*, from *less general* to *more general*, till, by a series of slow progression, and by regular degrees, it arrive at the *most general* notions, called FORMS, OR FORMAL CAUSES.[2] And by *affirming* or *denying* a genus of a species, or an accident of a substance or class of substances, through all the stages of the gradation, we form *conclusions*, which, if logically drawn, are AXIOMS,[3] or general propositions ranged one above another, till they terminate in those that are UNIVERSAL.

Of Reasoning.

The process of induction exemplified in physics.

4. Thus, for instance, *the evidence of the external senses* is obviously the PRIMARY PRINCIPLE from which all physical knowledge is derived. But, whereas nature begins with *causes*, which, after a variety of changes, produce *effects*, the senses open upon the *effects*, and from them, through the slow and painful road of experiment and observation, ascend to *causes.* By *experiments* and *observations* skilfully chosen, artfully conducted, and judiciously applied, the philosopher advances from one stage of inquiry to another in the rational investigation of the *general causes* of physical truth. From different experiments and observations made on the same individual subject, and from the same experiments and observations made on different subjects of the same kind, by comparing and judging, he discovers some *qualities, causes,* or *phenomena*, which, after carefully distinguishing and rejecting all contradictory instances that occur, he finds common to *many.* Thus, from many collateral comparisons and judgments formed upon *particulars* he ascends to *generals;* and by a repetition of the same industrious process and laborious investigation, he advances from *general* to *more general*, till at last he is enabled to form a few of the *most general*, with their attributes and operations, into AXIOMS or *secondary principles*, which are the well-founded *laws* enacted and enforced by the God of nature. This is that just and philosophic method of reasoning which sound logic prescribes in this as well as in other parts of learning; by which, through the slow but certain road of experiment and observation, the mind ascends from appearances to qualities, from effects to causes, and, from experiments upon many particular subjects, forms *general propositions* concerning the powers and properties of physical body.

Axioms applicable to all parts of learning.

5. AXIOMS so investigated and established are applicable to all parts of learning, and constitute the indispensable, and indeed the wonderful expedients, by which, in every branch of knowledge, reason pushes on its inquiries in the particular pursuit of truth; and the method of reasoning

---

[1] On the distinction of *logical* and *real induction*, a distinction hitherto wholly overlooked, see *Edinburgh Review*, vol. lvii. p. 224, et seq.

[2] "Qui *formas* novit, is, quæ adhuc non facta sunt, qualia nec naturæ vicissitudines, nec experimentales industriæ unquam in actum produxissent, nec cogitationem humanam subituræ fuissent, detegit et educit." (Baconi *Novum Organon.*)

[3] The word axiom, ἀξίωμα, literally signifies *dignity.* Hence it is used metaphorically to denote a *general truth* or maxim, and sometimes any truth that is self-evident, which is called a *dignity* on account of its importance in a process of reasoning. The axioms of Euclid are propositions extremely general; and so are the axioms of the Newtonian philosophy. But these two kinds of axioms have very different origins. The former appear true upon a bare contemplation of our ideas; whereas the latter are the result of the most laborious induction. Lord Bacon, therefore, strenuously contends that they should never be taken upon conjecture, or even upon the authority of the learned; but that, as they are the general principles and grounds of all learning, they should be canvassed and examined with the most scrupulous attention, "ut axiomatum corrigatur iniquitas, quæ plerumque in exemplis vulgatis fundamentum habent." (*De Augm. Scient.* lib. ii. cap. 2.) "Atque illa ipsa putativa principia ad rationes reddendas compellare decrevimus, quousque plane constant." (*Distrib. Operis.*) Dr Tatham makes a distinction between axioms *intuitive* and axioms *self-evident. Intuitive* axioms, according to him, pass through the first inlets of knowledge, and flash direct conviction on the minds, as external objects do on the senses, of all men. Other axioms, though not intuitive, may be properly said to be *self-evident*, because, in their formation, reason judges by single comparisons, without the help of a third idea or middle term, so that they have their evidence in themselves, and, though inductively framed, they cannot be syllogistically proved. If this distinction be just, and we think it is, only *particular* truths can be intuitive axioms.

by which they are formed is that of true and legitimate INDUCTION, which is therefore by Lord Bacon, the best and soundest of logicians, called the *key of interpretation.*

6. Instead of taking his axioms arbitrarily out of the great families of the categories, and erecting them by his own sophistical invention into the principles upon which his disputation was to be employed, had the analytical genius of Aristotle presented us with the laws of the true INDUCTIVE LOGIC, by which AXIOMS are philosophically formed, and had he with his usual sagacity given us an example of it in a single branch of science, he would have brought to the temple of truth an offering more valuable than he has done by the aggregate of all his logical and philosophical productions.

Induction prior to definition.

7. In all sciences, excepting the mathematics, it is only after the INDUCTIVE process has been industriously pursued and successfully performed, that DEFINITION may be logically and usefully introduced, by beginning with the *genus*, passing through all the graduate and subordinate stages, and marking the *specific difference* as it descends, till it arrive at the *individual*, which is the subject of the question. And by adding an *affirmation* or *negation* of the attribute of the *genus* or the *species* or *individual*, or of a general *accident* on the particular *substance* so defined, making the definition a proposition, the truth of the question will be logically solved, without any further process. So that, instead of being the *first*, as employed by the logic in common use, *definition* may be the *last* act of reason in the search of truth in general.

Prior also to syllogism.

8. These AXIOMS or general propositions, thus *inductively* established, become another species of PRINCIPLES, which may be properly called SECONDARY, and which lay the foundation of the syllogistic method of reasoning. When these are formed, but not before, we may safely admit the maxim with which logicians set out in the exercise of their art, as the great hinge on which their reasoning and disputation turn: "From truths that are already known, to deduce others which are not known;" or, to state it more comprehensively, so as to apply to probable as well as to scientific reasoning, "From truths which are better known, to deduce others which are less known." Philosophically speaking, syllogistic reasoning is, under *general propositions,* to reduce others which are *less general*, or which are *particular;* for the *inferior* ones are known to be true, only as we trace their connection with the *superior*. Logically speaking, it is to predicate a *genus* of a *species* or *individual* comprehended under it, or an *accident* of the *substance* in which it is inherent.

Induction and syllogism totally different.

9. Thus INDUCTION and SYLLOGISM are the two methods of *direct reasoning* corresponding to the two kinds of principles, *primary* and *secondary*, on which they are founded, and by which they are respectively conducted. In both methods, indeed, reason proceeds by *judging* and *comparing*, but the process is different throughout; and though it may have the sanction of Aristotle, an *inductive syllogism* is a solecism.

Induction the foundation of syllogism.

10. Till general truths are ascertained by induction, the *third* or *middle terms* by which syllogisms are made are nowhere safely to be found. So that another position of the Stagirite, *that syllogism is naturally prior in order to induction,*[1] is equally unfounded; for *induction* does not only naturally but necessarily precede *syllogism*, and, except in mathematics, is in every repect indispensable to its existence; since, till generals are established, there can be neither *definition, proposition,* nor *axiom*, and of course no syllogism. And as induction is the first, so is it the more *essential* and fundamental instrument of reasoning; for as syllogism cannot produce its own *principles*, it must have them from induction; and if the general propositions or secondary principles be imperfectly or infirmly established, and much more, if they be taken at hazard, upon authority, or by arbitrary assumption like those of Aristotle, all the syllogizing in the world is a vain and useless logomachy, and only instrumental in the multiplication of false learning, and the invention and confirmation of error. The truth of syllogisms depends ultimately on the truth of axioms, and the truth of axioms on the soundness of inductions.[2] But though induction is prior in order, as well as superior in utility, to syllogism, we have thought it expedient to treat of it last; both because syllogism is an easier exercise of the reasoning faculty than induction, and because it is the method of mathematics, the first science of reason in which the student is commonly initiated.

6. *Of Demonstration.*

1. Having concluded all that seemed necessary to be said in regard to the two methods of direct reasoning, the *syllogistic* and *inductive*, we now proceed to consider the laws of demonstration. And here it must be acknowledged, that in strict demonstration, which removes from the mind all possibility of doubt or error, the inductive method of reasoning can have no place. When the experiments and observations from which the general conclusion is drawn are numerous and extensive, the result of this mode of reasoning is moral certainty; and if the induction could be made complete, it would be absolute certainty, equally convincing with mathematical demonstration. But however numerous and extensive the observations and experiments may be upon which an inductive conclusion is established, they must of necessity fall short of the number and extent of nature; which, in some cases, by its immensity, will defeat all possibility of their co-extension, whilst, in others, by its distance, it lies out of the reach of their immediate application. Though truth does not appear in all other departments of learning with that bold and resistless conviction with which it presides in the mathematical sciences, it shines through them all, if not interrupted by prejudice or perverted by error, with a clear and an useful though inferior certainty. And as it is not necessary for the general safety or convenience of a traveller, that he should always enjoy the heat and splendour of a mid-day sun, whilst he can with more ease pursue his journey under the milder influence of a morning or an evening sky; so it is not requisite, for the various concerns and purposes of life, that men should be led by truth of the most redundant brightness. Such truth is to be had only in those sciences which are conversant about abstract ideas of space and number, and their various relations, where every thing being certainly what it appears to be, definitions and axioms arise from mere intuition. Here *syllogism* takes up the process from the beginning, and by a sublime intellectual motion advances from the simplest axioms to the most complicated speculations, and exhibits truth springing out of its first and

---

[1] This is a sad misrepresentation of Aristotle's doctrine. He makes the *deductive syllogism* prior in the *order of nature* to the *inductive syllogism*, as he makes the *state* in the same order prior to the *family*, and the family prior to the *individual*. But he expressly declares that the highest principles from which, in the syllogism proper, the deduction is made, are all the results of a foregone induction. The error arises from ignorance of the difference of a priority in the order of *nature* and *intention*, and priority in the order of *time* and *execution*.

[2] This chapter is almost wholly taken from Tatham's *Chart and Scale of Truth;* a work which, notwithstanding the ruggedness of its style, has so much real merit as a system of logic, that it cannot be too diligently studied by the young inquirer who wishes to travel by the straight road to the temple of science.

purest elements, and spreading upon all sides into a system of science. As each step in the progress is syllogistic, we shall endeavour to explain the use and application of syllogisms in this species of reasoning.

We have seen, that in all the different appearances they assume, we still arrive at a just and legitimate conclusion. Now, it often happens, that the conclusion of one syllogism becomes a previous proposition in another; by which means great numbers of them are sometimes linked together in a series, and truths are made to follow one another in a train. And as in such a concatenation of syllogisms all the various modes of reasoning which are truly conclusive may be with safety introduced, hence it is plain, that in deducing any truth from its first principles, especially where it lies at a considerable distance from them, we are at liberty to combine all the different kinds of syllogisms above explained, according as they are found best suited to the end and purpose of our inquiries. When a proposition is thus, by means of syllogisms, collected from others more evident and known, it is said to be *proved;* so that, in general, we may define the proof of a proposition to be a syllogism, or series of syllogisms, collecting that proposition from known and evident truths. But more particularly, if the syllogisms of which the proof consists admit of no premises but definitions, self-evident truths, and propositions already established, then is the argument so constituted called a *demonstration;* whereby it appears that demonstrations are ultimately founded upon definitions and self-evident propositions.

2. All syllogisms whatsoever, whether compound, multiform, or defective, are reducible to plain simple syllogisms in some one of the four figures. But this is not all. Syllogisms of the first figure, in particular, admit of all possible conclusions; that is, in any propositions whatsoever, whether universal affirmatives or universal negatives, particular affirmatives or particular negatives, which fourfold division embraces all their varieties, the conclusion may be inferred by virtue of some syllogism in the first figure. By this means it happens that the syllogisms of all the other figures are reducible also to syllogisms of the first figure, and may be considered as standing on the same foundation with them. We cannot here demonstrate and explain the manner of this reduction, because it would too much swell the bulk of this article. It is sufficient to notice, that the thing is universally known and allowed amongst logicians, to whose writings we refer such as desire further satisfaction in this matter. This, then, being laid down, it is plain that any demonstration whatsoever may be considered as composed of a series of syllogisms, all in the first figure. For, since all the syllogisms that enter the demonstration are reducible to syllogisms of some one of the four figures, and since the syllogisms of all the other figures are further reducible to syllogisms of the first figure, it is evident that the whole demonstration may be resolved into a series of these last syllogisms. Let us now, then, if possible, discover the ground upon which the conclusion rests in syllogisms of the first figure; because, by so doing, we shall come at an universal principle of certainty, whence the evidence of demonstrations in all their parts may be ultimately deduced.

3. The rules, then, of the first figure are briefly these. The middle term is the subject of the major proposition, and the predicate of the minor. The major is always an universal proposition, and the minor always affirmative. Let us now see what effect these rules will have in reasoning. The major is an universal proposition of which the middle term is the subject, and the predicate of the conclusion the predicate. Hence it appears, that in the major the predicate of the conclusion is always affirmed or denied universally of the middle term. Again, the minor is an affirmative proposition, of which the subject of the conclusion is the subject, and the middle term the predicate. Here then the middle term is affirmed of the subject of the conclusion; that is, the subject of the conclusion is affirmed to be comprehended under, or to form a part of, the middle term. Thus, then, we see what is done in the premises of a syllogism of the first figure. The predicate of the conclusion is universally affirmed or denied of some idea. The subject of the conclusion is affirmed to be or to form a part of that idea. Hence it naturally and unavoidably follows, that the predicate of the conclusion ought to be affirmed or denied of the subject. To illustrate this by an example, we shall resume one of the syllogisms of the first figure. "Every creature possessed of reason and liberty is accountable for his actions: Man is a creature possessed of reason and liberty: Therefore man is accountable for his actions."

Of Reasoning.

Here, in the first proposition, the predicate of the conclusion, *accountableness*, is affirmed of all creatures possessed of reason and liberty. Again, in the second proposition, *man*, the subject of the conclusion, is affirmed to be or to form a part of this class of creatures. Hence the conclusion necessarily and unavoidably follows, viz. that man is accountable for his actions; because, if reason and liberty be that which constitutes a creature accountable, and man has reason and liberty, it is plain he has that which constitutes him accountable. In like manner, where the major is a negative proposition, or denies the predicate of the conclusion universally of the middle term, as the minor always asserts the subject of the conclusion to be or form a part of that middle term, it is no less evident that the predicate of the conclusion ought in this case to be denied of the subject; so that the ground of reasoning, in all syllogisms in the first figure, is manifestly this: Whatever may be affirmed universally of any idea, may be affirmed of every or any number of particulars comprehended under that idea. And again, Whatever may be denied universally of any idea, may be in like manner denied of every or any number of its individuals. These two propositions are called by logicians the *dictum de omni*, and *dictum de nullo;* and they are indeed the great principles of syllogistic reasoning, inasmuch as all conclusions whatsoever rest immediately upon them, or upon propositions deduced from them. But what adds greatly to their value is, that they are really self-evident truths, and such as we cannot gainsay without running into an express contradiction. To affirm, for instance, that *no man is perfect*, and yet to argue that *some men are perfect;* or to say, that *all men are mortal*, and yet that *some men are not mortal;* is to assert a thing to be and not to be at the same time.

Demonstration an infallible guide to truth and certainty.

4. And now we may affirm, that, in all syllogisms of the first figure, if the premises be true, the conclusion also must needs be true. If it be true that the predicate of the conclusion, whether affirmative or negative, agrees universally to some idea; and if it be also true that the subject of the conclusion is a part of or comprehended under that idea; then it necessarily follows, that the predicate of the conclusion agrees also to the subject. For to assert the contrary, would be to run counter to some one of the two principles before established; that is, it would be to maintain an evident contradiction. And thus we have come at last to the point we have been all along endeavouring to establish; namely, that every proposition which can be demonstrated is necessarily true. For as every demonstration may be resolved into a series of syllogisms all in the first figure, and as in any one of these syllogisms, if the premises are true, the conclusion must needs be so likewise, it evidently follows, that if all the several premises are true, all the several conclusions are so, and consequently also the conclusion of the last syllogism, which is always the proposition to be demonstrated. Now, that all the premises of a demonstration are true, will easily appear from the very

nature and definition of that form of reasoning. A demonstration, as we have said, is a series of syllogisms, all whose premises are either definitions, self-evident truths, or propositions already established. Definitions are identical propositions, in which we connect the description of an idea with the name by which we choose to have that idea called, and therefore as to their truth there can be no dispute. Self-evident propositions appear true of themselves, and leave no doubt or uncertainty in the mind. Propositions, before established, are no other than conclusions gained by one or more steps from definitions and self-evident principles, that is, from true premises, and therefore must needs be true. Hence all the previous propositions of a demonstration being thus manifestly true, the last conclusion, or proposition to be demonstrated, must likewise be so; so that demonstration not only leads to certain truth, but we have here also a clear view of the ground and foundation of that certainty. For as, in demonstrating, we may be said to do nothing more than combine a series of syllogisms together, all resting on the same basis, it is plain that one uniform ground of certainty runs through the whole, and that the conclusions are everywhere built upon some one of the two principles before established, as the foundation of all our reasoning. These two principles are easily reducible into one, and may be expressed thus: Whatever predicate, whether affirmative or negative, agrees universally to any idea, the same must needs agree to every or any number of individuals comprehended under that idea. And thus at length we have, according to our first design, reduced the certainty of demonstration to one simple and universal principle, which carries its own evidence along with it, and which is indeed the ultimate foundation of all syllogistic reasoning.

Rules of logic furnish a criterion for distinguishing truth from falsehood.

5. Demonstration, therefore, serving as an infallible guide to truth, upon so sure and unalterable a basis, we may now venture to assert, that the rules of logic furnish a sufficient criterion for the distinguishing between truth and falsehood. For since every proposition that can be demonstrated is necessarily true, he is able to distinguish truth from falsehood who can with certainty judge when a proposition is truly demonstrated. Now, a demonstration, as we have said, is nothing more than a concatenation of syllogisms, all the premises of which are definitions, self-evident truths, or propositions previously established. To judge, therefore, of the validity of a demonstration, we must be able to distinguish whether the definitions that enter into it are genuine, and truly descriptive of the ideas they are meant to exhibit; whether the propositions assumed without proofs as intuitive truths have really that self-evidence to which they lay claim; whether the syllogisms are drawn up in due form, and agreeably to the laws of argumentation; in fine, whether they are combined together in a just and orderly manner, so that no demonstrable propositions serve anywhere as premises unless they are the conclusions of previous syllogisms. Now, it is the business of logic, in explaining the several operations of the mind, fully to instruct us in all these points. It teaches the nature and end of definitions, and lays down the rules by which these ought to be framed. It unfolds the several species of propositions, and distinguishes the self-evident from the demonstrable. It delineates also the different forms of syllogisms, and explains the laws of argumentation proper to each. In fine, it describes the manner of combining syllogisms, so that they may form a train of reasoning, and lead to the successive discovery of truth. The precepts of logic, therefore, as they enable us to judge with certainty when a proposition is duly demonstrated, furnish a sure criterion for the distinguishing between truth and falsehood.

6. Perhaps it may be objected, that demonstration is a thing very rare and uncommon, as being the prerogative of but a few sciences, and therefore the criterion here given can be of no great use. But wherever, by the bare contemplation of our ideas, truth is discoverable, there also demonstration may be attained. Now that is an abundantly sufficient criterion which enables us to judge with certainty in all cases where the knowledge of truth comes within our reach; for with discoveries that lie beyond the limits of the human mind we have properly no sort of business or concern. When a proposition is demonstrated, we are certain of its truth. When, on the contrary, our ideas are such as have no visible connection or repugnance, and therefore furnish not the proper means of tracing their agreement or disagreement, there we are sure that scientifical knowledge is not attainable. But where there is some foundation of reasoning, which yet amounts not to the full evidence of demonstration, there the precepts of logic, by teaching us to determine aright the degree of proof, and discern what is still wanting to render it full and complete, enable us to make a due estimate of the measures of probability, and to proportion our assent to the grounds upon which the proposition stands. And this is all we can possibly arrive at, or even so much as hope for, in the exercise of faculties so imperfect and limited as ours.

Distinction of d monstration into direct an indirect.

7. Before we conclude this branch of the subject, it may not be improper to take notice of the distinction of demonstration into *direct* and *indirect*. A *direct demonstration* is, when, beginning with definitions, self-evident propositions, or known and admitted truths, we form a train of syllogisms, and combine them in an orderly manner, continuing the series through a variety of successive steps, until at last we arrive at a syllogism the conclusion of which is the proposition to be demonstrated. Proofs of this kind leave no doubt or uncertainty behind them; because, all the several premises being true, the conclusions must likewise be so, and of course the very last conclusion or proposition to be proved. The other species of demonstration is the *indirect*, or, as it is sometimes called, the *apogogical*. The manner of proceeding here is, by assuming a proposition which directly contradicts that which we mean to demonstrate; and thence, by a continued train of reasoning, in the way of a direct demonstration, deducing from it some absurdity or manifest untruth. For hereupon we conclude that the proposition assumed was false, and thence again, by an immediate consequence, that the proposition to be demonstrated is true. Thus Euclid, in his third book, having to demonstrate *that circles which touch one another inwardly have not the same centre*, assumes the direct contrary of this, viz. *that they have the same centre;* and thence, by an evident train of reasoning, proves *that a part is equal to the whole.* The supposition therefore leading to this absurdity he concludes to be false, viz. *that circles touching one another inwardly have the same centre;* and thence again immediately infers, *that they have not the same centre.*

Ground o reasoning in indirect demonstrations.

8. Now, because this manner of demonstration is accounted by some not altogether so clear and satisfactory, we shall therefore endeavour to show that it equally with the other leads to truth and certainty. Two propositions are said to be *contradictory* of one another, when that which is asserted to be in the one is asserted not to be in the other. Thus the propositions, "Circles that touch one another inwardly have the same centre," and "Circles that touch one another inwardly have not the same centre," are *contradictories*, because the second asserts directly the contrary of that which is asserted in the first. Now, in all contradictory propositions, this holds universally, that one of them is necessarily true, and the other necessarily false. For if it be true that circles which touch one another inwardly have not the same centre, it is unavoidably false that they have the same centre. On the other hand, if it be false that they have the same centre, it is necessarily true that they have not the same centre. Since, therefore, it is impossible for them both to be true or both false at

the same time, it unavoidably follows that one is necessarily true and the other necessarily false. This, then, being allowed, which indeed is self-evident, if any two contradictory propositions are assumed, and one of them can by a clear train of reasoning be demonstrated to be false, it necessarily follows that the other is true. For as the one is necessarily true, and the other necessarily false, when we come to discover which is the false proposition, we thereby know the other to be true.

9. Now this is precisely the manner of an indirect demonstration, as is evident from the account which has been given of it above. For there we assume a proposition directly contradictory of that which we mean to demonstrate; and, having by a continued series of proofs shown it to be false, we thence infer that it is contradictory, or that the proposition to be demonstrated is true. As, therefore, this last conclusion is certain and unavoidable, let us next inquire after what manner we come to be satisfied of the falsehood of the assumed proposition, that so no possible doubt may remain as to the force and validity of demonstrations of this kind. The manner, then, is plainly this: Beginning with the assumed proposition, we, by the help of definitions, self-evident truths, or propositions already established, continue a series of reasoning, in the way of a direct demonstration, until at length we arrive at some absurdity or known falsehood. Thus Euclid, in the example before mentioned, from the supposition that circles touching one another inwardly have the same centre, deduces the inference *that a part is equal to the whole.* Since, therefore, by a due and orderly process of reasoning we come at last to a false conclusion, it is manifest that all the premises cannot be true; for, were all the premises true, the last conclusion must likewise be so, by what has been before demonstrated. Now, as to all the other premises made use of in the course of reasoning, they are by supposition manifest and known truths, being either definitions, self-evident propositions, or truths previously established. The assumed proposition is that only as to which any doubt or uncertainty remains. That alone, therefore, can be false; and, indeed, from what has been already shown, it must unavoidably be so. And thus we see that, in indirect demonstrations, two contradictory propositions being laid down, one of which is demonstrated to be false, the other, which is always the proposition to be proved, must necessarily be true; so that here, as well as in the direct mode of proof, we arrive at a clear and satisfactory knowledge of truth.

10. This is universally the method of reasoning in all apogogical or indirect demonstrations. But if any proposition is assumed, from which, in a direct train of reasoning, we can deduce its contradictory, the proposition so assumed is false, and the contradictory one true. For if we suppose the assumed proposition to be true, then, since all the other premises that enter the demonstration are also true, we shall have a series of reasoning consisting wholly of true premises; and hence the last conclusion or contradictory of the assumed proposition must be true likewise; so that by this means we should have two contradictory propositions both true at the same time, which is manifestly impossible. The assumed proposition, therefore, whence this absurdity flows, must necessarily be false; and consequently its contradictory, which is here the proposition deduced from it, must be true. If, then, any proposition is proposed to be demonstrated, and we *assume* the *contradictory* of that proposition, and thence directly infer the proposition to be demonstrated, by this very means we know that the proposition so inferred is true. For, since from an assumed proposition we have deduced its contradictory, we are thereby certain that the assumed proposition must be false; and if so, then its contradictory, or that deduced from it, which in this case is the same with the proposition to be demonstrated, must be true.

Of Method.

Knowledge of the principles of logic necessary to judge of demonstration.

11. We have a curious instance of this in the twelfth proposition of the ninth book of the Elements. Euclid there proposes to demonstrate, *that in any series of numbers, rising from unity in geometrical progression, all the prime numbers that measure the last term in the series will also measure the next after unity.* In order to this, he assumes the contradictory of the proposition to be demonstrated, namely, *that some prime number measuring the last term in the series does not measure the next after unity;* and thence, by a continued train of reasoning, proves that it actually does measure it. Hereupon he concludes that the assumed proposition is false; and that that which is deduced from it, or its contradictory, which is the very proposition he proposed to demonstrate, is true. Now that this is a just and conclusive way of reasoning, seems abundantly manifest from what has been so clearly established above. Whence it appears how necessary some knowledge of the rules of logic is to enable us to judge of the force, justness, and validity of demonstrations. For though it is readily allowed that, by the mere strength of our natural faculties we can at once discern, that of two contradictory propositions, the one is necessarily true and the other necessarily false, yet when they are so linked together in a demonstration as that the one serves as a previous proposition whence the other is deduced, it does not so immediately appear, without some knowledge of the principles of logic, why that alone, which is collected by reasoning, ought to be embraced as true, and the other, whence it is collected, should be rejected as false.

This of itself sufficient to guard us against false reasoning.

12. Having thus sufficiently evinced the certainty of demonstration in all its branches, and shown the rules by which we ought to proceed in order to arrive at a just conclusion according to the various ways of arguing made use of, it is needless to enter upon a particular consideration of those several species of false reasoning which logicians distinguish by the name of *sophisms.* He who thoroughly understands the form and structure of a good argument, will of himself readily discern every deviation from it. And although *sophisms* have been divided into many classes, which are all called by sounding names, that carry in them much appearance of learning, yet are the errors themselves so very palpable and obvious, that it would be lost labour to write for a man capable of being misled by them. Here, therefore, we choose to conclude this part of logic, and shall in the next give some account of *Method,* which, though inseparable from reasoning, is nevertheless always considered by logicians as a distinct operation of the mind, because its influence is not confined to the mere exercise of the reasoning faculty, but extends in some degree to all the transactions of the understanding.

IV.—OF METHOD.

General remarks.

We have now done with the three first operations of the mind, whose office it is to search after truth, and enlarge the bounds of human knowledge. There is yet a fourth, which regards the disposal and arrangement of our thoughts, when we endeavour so to put them together that their mutual connection and dependence may be clearly seen. This is what logicians called *Method,* and place always the last in order in explaining the powers of the understanding, because it necessarily supposes a previous exercise of our other faculties, and that some progress has been made in knowledge, before we can exert it in any extensive degree.

2. In this view it is plain that we must be beforehand well acquainted with the truths which we are to combine together, otherwise, how could we discern their several connections and relations, or so dispose of them as their mutual dependence may require? But it often happens that

the understanding is employed, not in the arrangement and composition of known truths, but in the search and discovery of such as are unknown. And here the manner of proceeding is very different. We assemble at once our whole stock of knowledge relating to any subject, and, after a general survey of things, begin with examining them separately and by parts. Hence it comes to pass, that although at our first setting out we were only acquainted with some of the grander strokes and outlines of truth, by thus pursuing her through her several windings and recesses we gradually discover those more inward and finer touches whence she derives all her strength, symmetry, and beauty. And here it is that when, by a narrow scrutiny into things, we have unravelled any part of knowledge, and traced it to its first and original principles, insomuch that the whole frame and contexture of it lies open to the view of the mind; here it is that, taking it the contrary way, and beginning with these principles, we can so adjust and put together the parts as the order and method of science requires.

3. But as these things are best understood when illustrated by examples, let us suppose any machine, for instance a watch, presented to us, the structure and composition of which we are as yet unacquainted with, but want, if possible, to discover. The manner of proceeding, in this case, is, by taking the whole to pieces, and examining the parts separately one after another. When by such a scrutiny we have thoroughly informed ourselves of the frame and contexture of each, we then compare them together, in order to judge of their mutual action and influence. By this means we gradually trace out the inward make and composition of the whole, and come at length to discern how parts of such a form, and so put together as we found in unravelling and taking them asunder, constitute that particular machine called a *watch*, and contribute to all the several motions and phenomena observable in it. This discovery being made, we can take things the contrary way, and, beginning with the parts, so dispose and connect them as their several uses and structures require, until at length we arrive at the whole itself, from the unravelling of which those parts resulted.

Ground of the analytic and synthetic methods.

4. And as it is in tracing and examining the works of art, so is it in a great measure in unfolding any part of human knowledge; for the relations and mutual habitudes of things do not always immediately appear upon comparing them one with another. Hence we have recourse to intermediate ideas, and by means of them are furnished with those previous propositions which lead to the conclusion we are in quest of. And if it so happen that the previous propositions themselves are not sufficiently evident, we endeavour by new middle terms to ascertain their truth, still tracing things backwards in a continual series, until at length we arrive at some syllogism where the premises are first and self-evident principles. This being done, we become perfectly satisfied as to the truth of all the conclusions we have passed through, inasmuch as they are now seen to stand upon the firm and immoveable foundation of our intuitive perceptions. And as we arrived at this certainty by tracing things backwards to the original principles whence they flow, so may we at any time renew it by a directly contrary process, if, beginning with these principles, we carry the train of our thoughts forward until they lead us, by a connected chain of proofs, to the very last conclusion of the series.

Division of method into analytic and synthetic.

5. Hence it appears, that in disposing and putting together our thoughts, either for our own use, that the discoveries we have made may at all times lie open to the review of the mind, or where we mean to communicate and unfold these discoveries to others, there are two ways of proceeding equally within our choice; for we may propose the truths relating to any part of knowledge, as they presented themselves to the mind in the manner of investigation, carrying on the series of proofs in a reverse order, until they at last terminate in first principles; or, beginning with these principles, we may take the contrary way, and from them deduce, by a direct train of reasoning, the several propositions which we want to establish. This diversity in the manner of arranging our thoughts gives rise to the twofold division of method established amongst logicians; for method, according to their use of the word, is nothing else but the order and disposition of our thoughts relating to any subject. When truths are proposed and put together as they were or might have been discovered, this is called the *analytical method*, or the *method of resolution;* inasmuch as it traces things backwards to their source, and resolves knowledge into its first and elementary principles. When, on the other hand, they are deduced from these principles, and connected according to their mutual dependence, insomuch that the truths first in order tend always to the demonstration of those which follow, this constitutes what we call the *synthetical method*, or the *method of composition;* for here we proceed by gathering together the several scattered parts of knowledge, and combining them into one whole or system, in such manner that the understanding is enabled distinctly to follow truth through all her different stages and gradations.

The method of invention, and the method of science.

6. There is this further to be taken notice of in relation to these two species of method, that the first has also obtained the name of the *method of invention*, because it observes the order in which our thoughts succeed one another in the invention or discovery of truth. The other, again, is often denominated the *method of doctrine* or *instruction*, inasmuch as, in laying our thoughts before others, we generally choose to proceed in the synthetic manner, deducing them from their first principles. For we have to observe, that although there is great pleasure in pursuing truth in the method of investigation, because it places us in the condition of the inventor, and shows the particular train and process of thinking by which he arrived at his discoveries, yet it is not so well accommodated to the purposes of evidence and conviction. At our first setting out, we are commonly unable to divine where the analysis will lead us, insomuch, indeed, that our researches are for some time little better than a mere groping in the dark. And even after light begins to break in upon us, we are still obliged to make many reviews, and a frequent comparison of the several steps of the investigation amongst themselves. Nay, when we have unravelled the whole, and reached the very foundation upon which our discoveries stand, all our certainty, in regard to their truth, will be found in a great measure to arise from that connection which we are now able to discern between them and first principles, taken in the order of composition. But in the synthetical manner of disposing our thoughts, the case is quite different. For, as we here begin with the intuitive truths, and advance by regular deductions from them, every step of the procedure brings evidence and conviction along with it; so that, in our progress from one part of knowledge to another, we have always a clear perception of the ground upon which our assent rests. In communicating our discoveries to others, therefore, this method is apparently to be chosen, as it wonderfully improves and enlightens the understanding, and leads to an immediate perception of truth.

7. The logic which for so many ages kept possession of the schools, and was deemed the most important of the sciences, has long been condemned as a mere art of wrangling, of very little use in the search after truth. Attempts have been made to restore it to credit, but without success; and for a considerable time little or no attention whatever has been paid to the science of logic in the course of what is called a liberal education. As both extremes may be faulty, it should seem that we cannot conclude this

of short treatise more properly than with some general observations on the utility of this science.

V.—OF THE UTILITY OF LOGIC.

If Aristotle was not the inventor of logic, he was certainly the prince of logicians. The whole theory of syllogisms he claims as his own property, the fruit of much time and labour; and it is universally known that the later writers on the art have borrowed their materials almost entirely from his *Organon* and Porphyry's *Introduction*. But after men had laboured nearly two thousand years in search of truth by the help of syllogisms, Lord Bacon proposed the method of induction as a more effectual engine for that purpose; and since his days the science of logic has gradually and undeservedly fallen into disrepute.

To this effect a variety of causes have contributed. The syllogistic art is admirably calculated for wrangling; and by the schoolmen it was employed with but too much success to keep in countenance the absurdities of the scholastic philosophy. Under their management it produced numberless disputes and numberless sects, who fought against each other with much animosity, without gaining or losing ground; but it did nothing considerable for the benefit of human life, whilst the method of induction has improved arts and increased knowledge. It is no wonder, therefore, that the excessive admiration of Aristotle, which continued for so many ages, should end in an undue contempt; and that the high esteem of logic, as the grand engine of science, should at last make way for the too unfavourable opinion which now seems prevalent, of its being unworthy of a place in a liberal education. Men rarely leave one extreme without running into the opposite. They who think according to the fashion of the time, will be as prone to go into the present extreme as their grandfathers were to go into the former; and even they who in general think for themselves, when they are offended at the abuse of any thing, are too apt to entertain prejudices against the *thing itself*. "In practice," says Bishop Warburton,[1] "logic is more a *trick* than a *science*, formed rather to amuse than instruct. And in some sort we may apply to the art of syllogism what a man of wit says of rhetoric, that it only tells us how to *name* those tools which nature had before put into our hands. In the service of chicane, indeed, it is a mere juggler's knot, now fast, now loose; and the schools where this legerdemain was exercised in great perfection are full of the stories of its wonders." The authority of Warburton is great, but it may be counterbalanced by another, which, on subjects of this nature, is confessedly greater.

"Laying aside prejudice, whether fashionable or unfashionable, let us consider," says Dr Reid,[2] "whether logic is or may be made subservient to any good purpose. Its professed end is to teach men to think, to judge, and to reason with precision and accuracy. No man will say this is a matter of little importance; the only thing therefore that can admit of doubt is, whether it can be taught?

"To resolve this doubt, it may be observed, that our rational faculty is the gift of God, given to men in very different measures. Some have a large portion, some a less; and where there is a remarkable defect of the natural power, it cannot be supplied by any culture. But this natural power, even where it is the strongest, may lie dead for want of the means of improvement. Many a savage may have been born with as good faculties as a Newton, a Bacon, or an Aristotle; but their talents were buried by having never been put to use, whilst those of the philosophers were cultivated to the best advantage. It may likewise be observed, that the chief mean of improving our rational power, is the vigorous exercise of it in various ways, and on different subjects, by which the habit is acquired of exercising it properly. Without such exercise, and good sense over and above, a man who has studied logic all his life may be only a petulant wrangler, without true judgment or skill of reasoning in any science."

This must have been Mr Locke's meaning, when, in his Thoughts on Education, he says, "If you would have your son to reason well, let him read Chillingworth." The state of things is much altered since Locke wrote. Logic has been much improved chiefly by his writings; and yet much less stress is laid upon it, and much less time consumed in its study, than formerly. His counsel, therefore, was judicious and seasonable, viz. That the improvement of our reasoning powers is to be expected much more from an intimate acquaintance with the authors who reason best, than from studying voluminous systems of scholastic logic. But if he had meant, that the study of logic was of no use, nor deserved any attention, he surely would not have taken the pains to make so considerable an addition to it, by his *Essay concerning Human Understanding*, and by his *Thoughts on the Conduct of the Understanding;* nor would he have remitted his pupil to Chillingworth, the acutest logician as well as the best reasoner of his age.

It must indeed be confessed, that a man without knowing the rules of logic may acquire a habit of reasoning justly in *mathematics*, and perhaps in any other science. Good sense, good examples, and assiduous exercise, may bring a man to reason justly and acutely in his own profession without rules. But whoever thinks, that from this concession he may infer the inutility of logic, betrays by this inference a great want of sense; for he might as well infer that, because a man *may* go from Edinburgh to London by the way of Paris, therefore *any other* road is useless.

There is perhaps no art which may not be acquired in a very considerable degree, by example and practice, without reducing it to rules. But practice conjoined with rules may carry a man forward in his art farther and more quickly than practice without rules. Every ingenious artist knows the utility of having his art reduced to rules, and thereby rendered a science. By rules he is enlightened in his practice, and works with more assurance. They enable him sometimes to correct his own errors, and often to detect the errors of others; and he finds them of great use to confirm his judgment, to justify what is right, and to condemn what is wrong. Now mathematics are the *praxis* of *logic*. Through them we may perceive how the stated forms of syllogism are exemplified in one subject, namely, the predicament of quantity; and by marking the force of these forms as they are there applied, we may be enabled to apply them of ourselves elsewhere. Whoever, therefore, shall study mathematics with this view, will become not only by mathematics a more expert *logician*, and by logic a more rational *mathematician*, but a wise philosopher, and an acuter reasoner on all the possible subjects either of science or deliberation. But when mathematics, instead of being applied to this excellent purpose, are used, not to exemplify logic, but to supply its place, no wonder if logic should fall into contempt, and if mathematics, instead of furthering science, should become in fact an obstacle. For when men, knowing nothing of that reasoning which is *universal*, come to attach themselves for a series of years to a *single species*, a species wholly involved in *lines* and *numbers*, the mind becomes incapacitated for reasoning at large, and especially in the search of *moral truth*. The object of mathematics is *demonstration;* and whatever in

Utility of Logic.

that science is not demonstration, is nothing, or at least below the regard of the geometrician. *Probability*, through its almost infinite degrees, from simple ignorance up to absolute certainty, is the *terra incognita* of the mathematician; and yet here it is that the great *business* of the human mind is carried on in the search and discovery of all the important truths which concern us as reasonable beings; and here too it is that all its *vigour* is exerted; for to proportion the assent to the probability accompanying every varying degree of moral evidence, requires the most enlarged and sovereign exercise of reason.

In reasonings of this kind, will any man pretend that it is of no use whatever to be well acquainted with the various powers of the mind by which we reason? Is it of no use to resolve the various kinds of reasoning into their simplest elements; and to discover, as far as we are able, the rules by which these elements are combined in judging and in reasoning? Is it of no use to mark the various fallacies in reasoning, by which even the most ingenious men have been led into error? It must surely betray great want of understanding to think these things useless or unimportant. Now these are the things which logicians have attempted; and which they have also executed, not indeed so completely as to leave no room for improvement, but in such a manner as to give very considerable aid to our reasoning powers. That the principles they have laid down with regard to definition and division, the conversion and opposition of propositions, and the general rules of reasoning, are not without use, is sufficiently apparent from the blunders daily committed by those who disdain to cultivate any acquaintance with them.

Although the art of categorical syllogism is confessedly little fitted for the discovery of unknown truths, it may yet be employed to excellent purposes, as it is perhaps the most compendious method of detecting a fallacy. A man in quest of unknown truths, must generally proceed, by the method of induction, from effects to causes; but he who as a teacher has to inculcate any system upon others, begins with one or more self-evident truths, and proceeds, in the way of demonstration, to the conclusion which he wishes to establish. Now every demonstration, as has been already observed, may be resolved into a series of syllogisms, of which the conclusion of the preceding always enters into the premises of that which follows; and if the first principles be clear and evident, and every syllogism in some legitimate mode and figure, the conclusion of the whole must infallibly be admitted. But when the demonstration is thus broken into parts, if we find that the conclusion of one syllogism will not, without altering the meaning of the terms, enter legitimately into the premises of that which should immediately follow; or, supposing it to make one of the premises of a *new* syllogism, if we find that the conclusion resulting from the whole series *thus* obtained, is different from that of the demonstration; we may, in either of these cases, rest assured that the author's reasoning is fallacious, and leads to error; and that if it carried an appearance of conviction before it was thus resolved into its elementary parts, this must have been owing to the inability of the mind to comprehend at *once* a long train of arguments. Whoever wishes to see the syllogistic art employed for this purpose, and to be convinced of the truth of what we have said respecting its utility, may consult the excellent writer recommended by Mr Locke, who, in places innumerable of his incomparable book, has, without pedantry, even in that pedantic age, made the happiest application of the rules of logic for unravelling the sophistry of his Jesuitical antagonist.

Upon the whole, then, although we readily acknowledge that much time was wasted by our forefathers in syllogistic wrangling, and what might with little impropriety be termed the *mechanical* part of logic, yet the art of forming and examining arguments is certainly an attainment not unworthy the ambition of a being whose highest distinction it is that he is endowed with reason.

Genera
Observa
tions.

The preceding article was written at a period when some views in regard to the object and the end of logic were entertained in this country, which, in the present state of the science, would be regarded as incorrect. The influence of these views upon this treatise does not, however, affect its utility. They are observable more in the *definition* than in the *treatment* of the subject. It is, accordingly, sufficient to correct the former, by showing what is the true scope and peculiar province of logic, and to point out to the reader the more accessible sources to which he may resort.

The common error, in which Bacon participated, of identifying *logical* (formal) and *philosophical* (real) induction; and the errors of Locke in supposing that logic supplied any peculiar method of reasoning, and that syllogism was ever intended as an instrument of *discovery;* had afforded to these philosophers a ground on which they found no difficulty in demonstrating the comparative inutility of the whole logical system of Aristotle. Nor was the fallacy of their refutation soon exposed by detecting the defect in its foundation. On the contrary, in this country, and in some others, it was long admitted to be conclusive; and this admission in a great measure determined the mode in which the subject was treated by the greater number of those British authors who subsequently presented to the public what they denominated systems of logic. Instead of showing that this science was only undervalued for not effecting what it really did not propose to accomplish; instead of showing that the end which it does propose is of high importance, and is fully accomplished by this science, and by this science alone; and, instead of rigorously excluding from their systems all not necessarily conducive to this end; they, on the contrary, proposed to logic an end which no one science could possibly accomplish; and in attempting this, they transmuted the most certain, definite, and independent of the philosophical sciences, into a precarious assemblage of foreign, incoherent, and insecure materials. Logic was regarded as the doctrine which taught the art of using rightly our intellectual faculties in the acquisition of knowledge; but as the promise here necessarily stood in melancholy contrast with the performance, this false and exaggerated estimate of the science only contributed to sink still lower the humble opinion now entertained of its importance.

Logic may be defined *the science of the laws of thought, considered as thought.* This is the central notion towards which the various views of the science from Aristotle down wards gravitate; it is the one definition, in which others, apparently the most opposite, find their complement and reconciliation. This definition, however, requires some elucidation.

In the first place, logic is said to be conversant about *thought.* The term thought properly denotes a self-active or spontaneous operation of the mind upon its objects, and in opposition to those passive determinations by which these objects are originally received into the mind, or subsequently suggested to its view. Logic is thus confined to the discursive agency of mind in its three degrees of Apprehension, Judgment, and Reasoning, to the exclusion of the subordinate operations of perception, imagination, and memory. Those who limit the definition of logic to *Reasoning*, are incorrect, inasmuch as, though the laws of reasoning are the principal, they are not the adequate object of the science. Those also are wrong who make logic proximately conversant about *language*, thus confounding it with grammar. We may, however, with the schools, il-

General Observations.

lustratively style logic the *grammar of thought*, as general grammar may analogically be termed the *logic of speech*.

In the second place, logic is conversant about *thought considered as thought*. In every act of thinking we distinguish by reflection two things: 1. the object of thought (the matter); 2. the mode of thinking it (the form). For example, when I think "This pen is bad," the matter of the thought is *the bad pen*; the *form* in which the matter is contained is a *judgment*. Again, the word "animal," in so far as it is viewed as expressive of a *certain conceived multitude of living existences*, is material; in so far as it is considered as only significant of a *general notion*, it is formal. This distinction of material and formal in thought was also expressed by the schoolmen in the contrast of *entia realia* and *entia rationis*, of *notiones* (intellecta, conceptus, intentiones) *primæ*, and *notiones secundæ*. This distinction is indeed only a mental abstraction for the sake of science, as the matter and the form of thought are in reality inseparable; for we are conscious of no object excepting under some form of thought, and of no form of thought without a reference to some determinate matter which constitutes the object of thought. Of these, the matter is infinite in variety and number; the form, of few and determinate modifications. Logic, therefore, can only consider the form of thought. For if it took the matter into account, it must either take *all* objects indifferently, or only *some*. On the former principle, logic would be a treatise upon the *omne scibile*, a complement of all the sciences, which is impossible and absurd; and upon the latter, no reason can be shown why certain objects should be selected for consideration, to the exclusion of all others. But if we can neither make all nor some objects of thought the object-matter of logic, it only remains that we propose as its object-matter the form of thought itself; that is, that we consider in logic, thought as thinking, to the neglect of the particulars about which it thinks. Nor is this view of the province of logic any novelty. In the schools, to say nothing of more recent philosophers, logic was universally viewed as a *rational* not a *real*, as a *formal* not a *material* science; in other words, as conversant, not about *things* as conceived or known, but about the *mode* of conceiving and knowing them. Its object-matter was thus by the schoolmen limited to *entia rationis*, in contrast to *entia realia*; to *notiones secundæ*, in contrast to *notiones primæ*; *to things in general, in so far as they stand under second notions, &c.*; expressions which, when rightly understood, manifest that those persons who employed them held views, in regard to the scope and domain of the science, far more accurate than those latterly prevalent, at least in this country.

In the third place, logic is the science of the *laws* of thought. Logic, as we have seen, is solely conversant about the faculty of thought, considered in its formal relation. But the forms of thought can be made the object of consideration from two points of view. We can either contemplate them as objects of mere *experience*, that is, delineate and arrange the special modifications of the thinking principle, as facts of observation and history; or we may regard them as objects of *speculation*, that is, by means of reflection and abstraction seek out and determine what, as necessary in each act of thinking, affords the condition of the possibility of thought in general. The consideration of the human mind, as an object of experience, belongs not to logic, but to psychology. A knowledge, indeed, of the phenomena of mind, as facts of experience, must chronologically precede their consideration as objects of speculation; the philosophy of the human mind, as an empirical science, forms therefore the natural preliminary of logic as a speculative science. Logic in itself, however, constitutes not the less an independent and exclusive system. For where the knowledge of our intellectual nature founded upon observation and induction ends, and where, by an abstraction from all that experience affords of particular and contingent, we ascend by reflection to the universal, and necessary, and *a priori* conditions it involves, there the domain of logic commences, and that of psychology, as a doctrine explanatory of mere facts, terminates. But if logic be conversant about the universal and necessary in thought, it is thereby conversant about the *laws of thought*. For the universal and necessary is only conceived as what is determined by laws; and again, the very conception of a law involves the universality and necessity of its application.

Logic is thus conversant, not about thought considered in itself, but about thought viewed as subject to laws. Those therefore who, without qualification, make the *operations or processes* of the discursive faculty the object of logic, are wrong; for logic considers these only as governed by laws. Nor is this any modern observation. "To treat of thoughts as thoughts," says Simplicius, "is not the function of logic, but of psychology." Those schoolmen who held *entia rationis* or *notiones secundæ* to be the object of logic, did not propose that these should be considered in themselves, but only in their application to *entia realia* or *notiones primæ*, as the instruments and regulators of thought; whilst those again who proposed all or some of the three intellectual operations for this object, did so only in as far as these were *dirigible* or determinable by laws.

Thus the same correct view of the science may be detected under forms of expression which at first sight appear to be the most contradictory; and what we have shown in regard to the schoolmen may be more easily proved in regard to the Leibnitzian and Kantian logicians. But though a right conception of the scope and limits of logic must be allowed to have long and generally prevailed, it must be acknowledged that the speculative notion did not in practice regulate the contents and treatment of the science. From Aristotle downwards (the example and authority of the Stagirite having mainly determined the practice of his successors), the purity of the science has been, and is still, contaminated by foreign infusions; and it is only by slow and painful efforts that one extraneous doctrine after another has been banished from its domain. Thus, though it has always been speculatively allowed that logic is exclusively conversant with the form of thought; yet a consideration of the material modality of propositions and syllogisms (a subject as useless as it is irksome) remained, though often overlooked, an integral portion of the science, until it was proved to be intrusive in the article on logic in the *Edinburgh Review* (vol. lvii. p. 220, *et seq.*), and has accordingly, by subsequent writers on the science, been formally expunged, as paralogical, from their systems. In this country there is, however, no work on logic which displays the science in a pure and perfect form; which evolves its doctrines from fundamental principles, and displays its parts in that necessary connection and dependence, which constitutes the elegance of a scientific system. Whately's *Elements of Logic* is the English book which is best deserving of attention. Though somewhat vague and vacillating in its views of the science, and though its doctrines are neither developed from the primary laws of thought, nor combined together as the essential parts of one necessary whole, yet it displays a talent which shows that the author, with a more comprehensive knowledge of his subject, might have produced a work not easily to be superseded. There are also several minor works recently published on logic in this country, not unworthy of consideration, a detailed estimate of which may be seen in the Review previously referred to.

LOGISTÆ, certain officers at Athens, ten in number, whose business consisted in receiving and passing the accounts of magistrates when they went out of office. The *logistæ* were elected by lot, and had under them ten *euthyni* or auditors of accounts.

LOGOGRAPHY, a method of printing, in which the types, instead of answering only to single letters, are made to correspond to entire words. In the year 1783, there appeared a treatise upon this subject by Henry Johnson, in which the origin as well as the utility of the method are largely discussed. Mr Johnson informs us, that about five years before, that is, in the year 1778, intending to publish a daily list of blanks and prizes in the lottery, numerically arranged, he found that it could not be accomplished in time by the ordinary method of printing. On this account he procured types of two, three, or more figures, as was necessary for this purpose; and thus any entire number might as readily be taken up as if it had been a single type. His next attempt was in forming some large mercantile tables of pounds, shillings, pence, and farthings. For these he procured types expressive of any sum of money ready composed and united; "by which every species of figure-printing could be performed for the tenth part of the cost, printers always charging it double the price of letter-printing." Having thus succeeded to his wish in his two first attempts, he next began to consider if the method could not be applied to words; and in this also the success, he says, was equal. The properties of the logographic art, according to its author, are, 1*st*, that the compositor shall have less charged upon his memory than in the common way; 2*d*, that it is much less liable to error; 3*d*, that the type of each word is as easily laid hold of as that of a single letter; 4*th*, that the decomposition is much more readily performed, even by the merest novices, than the distribution of letters; 5*th*, that no extraordinary expense, nor greater number of types, is required in the logographic than in the common method of printing. But, for fuller details, we must refer to the work above mentioned.

LOGRONO, a town of Spain, in the province of Old Castille. It is situated on the banks of the Ebro, in a fertile territory, in which oil, wine, and some corn is produced. It has three parish churches, nine monasteries, two hospitals, and 7000 inhabitants, and was the seat of a court of inquisition.

LOIRE, the largest river in France, rises in the mountains of the Cevennes, and, after running a course of about 500 miles, falls into the Bay of Biscay.

Loire, a department of the south-east of France, formed out of the whole district of Forez, a part of the Lyonnois, and a few portions added from the neighbouring departments. It extends in north latitude from 45. 10. to 46. 12. and in east longitude from 3. 39. to 4. 46. It contains 2032 square miles, or 496,000 hectares. It is bounded on the north by the departments of Allier and Saone-Loire, on the east by those of the Rhone and of the Isère, on the south by Ardèche and the Upper Loire, and on the west by Puy de Dome and Allier. It comprehends three arrondissements and twenty-eight cantons, which are subdivided into 327 communes, and contain a population of 318,500 persons. The face of the country is generally hilly, and towards the south-east is mountainous, where Mount Pilat attains the height of 3000 feet. With this is connected a chain, of lower elevation, called the Pérouse Range, which, from the vast quantity of basalt, is supposed to be extinguished volcanoes. The greatest plain is the basin of the Loire, which is about fifteen miles in extent. The highest mountains are stony, and many of them incapable of cultivation. The sides of the hills, and even the tops of those of lower elevation, are covered with vineyards; and the basin of the Loire, and the other plains in the valleys, are fertile, and yield abundant crops of corn, and much hemp. The chief river is the Loire, which is navigable from Roane, receives the waters of the Semene, the Bonson, the Furand, the Lignon, the Rahins or Rhine, and the Tessonne, as well as that of many smaller streams that issue from the hills. In the middle of the department, especially in the arrondissement of Montbrison, are a multitude of lakes, which abound in fish, the water of which is let off every two or three years, and the ground is sowed with wheat, and thus alternately the land produces fish and corn. The whole growth of corn does not equal the consumption; but the deficiency is supplied from the neighbouring departments, which take hemp in exchange for it. The chief products of the soil are, wine, fruit, honey and wax, chestnuts, wood for building and fuel, and the flesh of sheep, cows, and goats, with cheese made from the two latter classes of animals. The agriculture is but indifferently conducted. Many of even the valleys grow only rye, and the produce of some scarcely equals the expense of raising it. There are numerous coal-mines worked, which yield annually 300,000 tons of that substance. Mines of lead and of iron are also worked, but scarcely yield more of those metals than is consumed within the department. The quarries of granite, marble, porphyry, and flint, are sources of employment and wealth. The chief manufacturing industry is occupied in making ironmongery and cutlery goods; and, besides these trades, many silk goods, chiefly ribbons, are prepared, and cloth of cotton, of wool, and of hemp, with brandy, paper, glass, and leather. The department elects two deputies to the legislative chamber. The capital is Montbrison.

Loire, *Lower*, a department of France, formed out of a part of Upper Bretagne, extending in north latitude from 46. 44. to 47. 50. and in west longitude from 1. 6. to 2. 39. It is bounded on the north by the departments of Morbihan and Ille-Vilaine, on the east by those of Mayenne and Mayenne-Loire, on the south by Vendée, and on the west by the ocean. It is divided into five arrondissements, forty-five cantons, and 209 communes, and contains 417,120 inhabitants. The extent is 3021 square miles, or 766,000 hectares. Of this land, 268,100 hectares are under the plough, 105,700 are pastures and morasses, 137,800 are not cultivated, 82,780 consist of vineyards, 80,430 are woods and forests, and the remainder are the sites of towns and villages, roads, rivers, and salt marshes. The face of the country is generally level, but interspersed with a few hills of inconsiderable height. The highest of them are covered with a vegetable or clayey soil, resting on a bed of granite or schist. In some districts the overflooding has created extensive turf ground, which is applied to the purposes of fuel. The agriculture is in a backward state, though somewhat improved of late years. In the northern portion of the department, wheat, and in greater proportion rye, buckwheat, and pulse, form the grain crops, but in the south-west, wheat is the principal grain; yet the whole corn grown is scarcely more than three fifths of what the consumption requires. The meadows on the left banks of the Loire pasture many cows, and the butter from the dairies is much esteemed. The cultivation of the vine is an important object of industry, especially in the arrondissements of Savenai, Ancenis, and Nantes. The greater part of the wine is converted into brandy. Apples are the most abundant fruit, and a great quantity of cider is made from them in several districts. There are mines of iron and of coal, but the former are not highly productive, and only yield 1000 tons annually; the latter are said to be equal in quality to the best coals of England. The principal manufacture is that of linen; but of late the cotton trade has been much extended, and in printed cotton a great progress has been made, and a large quantity is fabricated. The chief trade is concentrated in the city of Nantes, the capital. A large portion of culinary salt is collected from the marshes on the sea-shore. The river Loire conveys to the sea the water of most of the other streams. The department elects four members of the legislature.

Loire, *Upper*, a department on the south-east of France, formed out of the ancient district of Belay, a part of Languedoc, of a portion of the Upper Auvergne, and of some communes taken from Gévaudun, Vivarais, and Forez. It extends in north latitude from 44. 48. to 45. 25. and in east longitude from 3. 4. to 4. 18. It is bounded on the north by the departments of Puy de Dome and Loire, on the east and south-east by the Ardèche, on the south by the Lozère, and on the west by Cantal. It contains 1920 square miles or 502,854 hectares, is divided into three arrondissements, twenty-eight cantons, and 272 communes, and contains 272,600 inhabitants, of whom about 5000 are Protestants, and the others adhere to the Catholic church. It is generally a mountainous district, consisting of some branches of the range of the Auvergne, and some of the Cevennes range, the highest points of both of which are within this department. The soil is generally of volcanic origin, consisting in a great measure of lava or pozzolana. It is dry and hard, but in the valleys is not wholly unproductive. The principal rivers are the Loire and the Allier, which receive the waters of the several smaller streams; but neither of them become navigable till they have passed out of this department. There are several small mountain lakes, the most extensive of which is that of Bouchet. Although, from the mountainous nature of the district, it is better calculated for pasture than for the plough, yet, as the sides of the hills are cultivated like gardens, and easily irrigated, sufficient corn is grown for the consumption of the population. The chief source of profit in husbandry is the breeding of black cattle and of horses, and making butter and cheese. Fruit is extensively produced, particularly chestnuts and apricots. The bees yield abundance of honey and wax, both of which form branches of the export trade. There are no mines but those of coal, which yield about 18,000 tons yearly. Manufactures are inconsiderable, consisting chiefly of linen goods, and some lace, both of silk and thread. The other articles are those for domestic use, such as leather, heavy ironmongery, and common earthenware. The department furnishes two deputies to the legislative chamber. The capital is Puy en Belay.

Loire and Cher, a department of France, formed out f the ancient divisions of Blesois and Cologne, in the Or-eannois. It extends in north latitude from 47. 18. to 48. 4. nd in east longitude from 0. 28. to 1. 57. It contains 2647 quare miles, or 671,500 hectares, of which 320,000 are rable land, 70,000 are woods, 20,000 are vineyards, and he rest pastures, meadows, rivers, roads, and the sites of owns and villages. It is bounded on the north by the department of the Eure-Loire, on the north-east by Loiret, n the south-east by the Cher, on the south by the Indre, n the south-west by the Indre-Loire, and on the north-est by the Sarthe. It is divided into three arrondisse-ents, twenty-four cantons, and 309 communes, and con-ins a population of 220,000 persons, amongst whom it said there are scarcely 20,000 who can read and write. he department is a level district, with a few inconsidera-e elevations, which are covered with vines. The south-n part or arrondissement of Romorantin is a miserable strict, filled with heaths and swamps, between which only e spots of cultivable land scattered over it, in which are nall and wretched villages. The northern part contains larger proportion of cultivated soil, but is filled with san- heaths, sometimes mixed with clay or chalk, but often-er with pebbles. There are numerous small streams, all of which empty themselves into the two rivers which give their name to the department. No part of France contains so many small lakes and swamps. The agriculture is badly conducted. In many of the cantons no wheat is grown, and in some the only corn is buckwheat, which, with rye from the vicinity, forms the chief bread of the inhabitants. Along the banks of the rivers there are some meadows, which afford pasture for cows; and some good butter and cheese is produced. A number of horses, of a small but active race, are bred on the heathy lands. The land is divided into small portions, and cultivated for the most part by small and poor proprietors. The wine made in the department is chiefly sent to Orleans or Paris, but a great part of it is converted into brandy. The only product of the mines is iron; but flints for muskets are abundantly found, and the army is chiefly supplied from hence. The only manufacturing industry is the spinning of flax, which is carried on in every family. The department elects two deputies to the legislative chamber. The capital is the city of Blois.

LOIRET, a department of France, formed out of a part of the ancient Orleannois. It extends in north latitude from 47. 35. to 48. 22. and in east longitude from 1. 24. to 2. 59., comprehending 2789 square miles, or 675,191 hectares. It is bounded on the north by the departments of the Seine and Oise and the Seine and Marne, on the east by Yonne, on the south by the Nièvre, the Cher, and the Cher and Loire, and on the west by the Eure and Loire. It is divided into four arrondissements, fourteen cantons, and 111 communes, whose population amounts to 134,500 persons. It is, as a whole, a fruitful plain; but, upon the right side of the Loire, it is well covered with profitable forests. The soil is light and sandy, especially in the arrondissement of Montargis, but highly productive, although it scarcely affords a sufficiency of corn for the consumption of the inhabitants. Wine is the most valuable article of cultivation, and both red and white wine of good quality are made, as well as much vinegar and brandy. It is favourably situated for the conveyance of its productions by internal navigation. Much fruit, as well as wood, is conveyed by water to Paris. There are manufactures of cotton and of linen goods, of hosiery, paper, and leather, and some refineries for sugar. The department elects three deputies to the legislative body. The capital is the city of Orleans.

LOJA, or Loxa, a city of Spain, in Granada, within the province of Andalusia. It is situated about twenty miles from the city of Granada, in a gorge between the stupendous mountains which seem to shut in the plain from the rest of the kingdom. At the bottom of this fissure, the river Xenil runs from the plain, and the streets of the city rise above each other on the declivities of the mountain. It was a place of vast military importance when the Moors were in possession of Granada, as it is the only entrance on the western side of the plain. The surrounding country is thickly covered with olive woods, which yield a great quantity of oil. Some corn is raised, but not sufficient for the population, who are supplied with the remainder by exchanging oil. It contains about 9000 inhabitants.

LOKE, in *Mythology*, the name of one of the deities of the northern nations, answering to the Ahriman of the Persians, whom they represent as at enmity with both gods and men, and the author of all the evils which desolate the universe. Loke is described in the Edda as producing the great serpent which encircles the world (which seems to have been intended as an emblem of corruption or sin); and he also gives birth to Hela or death, the queen of the infernal regions, and to the wolf Fenris, the monster who is destined to encounter the gods and to destroy the world.

LOKEREN, a large market-town of the Netherlands, in the province of East Flanders, and the arrondissement of the Dender. It is situated on the river Durme, on the high road from Ghent to Antwerp. It stands in a district yielding heavy crops of corn, hemp, flax, and clover and linseed, which form its chief objects of commerce. It has also manufacturing establishments for making cotton and linen goods, lace, and other goods. It contains 1800 houses, with 12,800 inhabitants.

LOKMAN THE WISE, an eminent philosopher amongst the orientals. The Arabians say he was the son of Baura, the son or grandson of a sister or aunt of Job. He was an Ethiopian, and for some time a slave. It is related that he was born in the time of David, and that he lived till the age of the prophet Jonah. Some suppose him to have been the same with Æsop the mythologist; and indeed we find in the parables or apologues of Lokman in Arabic many particulars which are seen in Æsop's fables, so that it is not easy to determine whether the Greek or the Arabian are the originals. He is said to have been deformed in his person; but this defect was sufficiently compensated by the perfections of his mind. Some pieces of his are extant; and he was looked upon as so excellent a person, that Mahommed has inserted a chapter in the Koran called after his name, in which he introduces God as saying, "We heretofore bestowed wisdom on Lokman." It is related that he obtained his liberty upon the following occasion. His master having given him a bitter melon to eat, he ate it all. Surprised at his exact obedience, his master asked him, How it was possible for him to eat such a nauseous fruit? He answered, "I have received so many favours from you, that it is no wonder I should once in my life eat a bitter melon from your hand." This generous answer of the slave struck the master to such a degree, that he immediately gave him his liberty. A French translation of the fables of Lokman, and of Bidpai or Pilpay, a Brahminical philosopher, by M. Galland, was published at Paris in 1724.

LOLLARDS, in *Ecclesiastical History*, a religious sect, which arose in Germany about the beginning of the fourteenth century, and was so called, as many writers have thought, from Walter Lollard, who began to dogmatize in 1315, and was afterwards burned at Cologne; though others think that Lollard was no surname, but merely a term of reproach applied to all heretics who concealed the poison of error under the appearance of piety.

The monk of Canterbury derives the origin of the word Lollard amongst us, from *lolium*, a tare; as if the Lollards were the tares sown in Christ's vineyard. Abelly says that the word Lollard signifies praising God, from the German *loben*, to praise, and *herr*, Lord; because the Lollards employed themselves in travelling about from place to place, singing psalms and hymns. Others, again, derive *lollhard*, *lullhard*, or *lollert*, *lullert*, as it was written by the ancient Germans, from the old German word *lullen*, *lollen*, or *lallen*, and the termination *hard*, with which many of the Dutch words end. *Lollen* signifies to sing with a low voice, and therefore Lollard is a singer, or one who frequently sings; and in the vulgar tongue of the Germans it denotes a person who is continually praising God with a song, or singing hymns in his praise. The Alexians or Cellites were called *Lollards*, because they were public singers, who made it their business to inter the bodies of those who died of the plague, and sang a dirge over them in a mournful and indistinct tone as they carried them to the grave. The name was afterwards assumed by persons who dishonoured it; for we find that, amongst those Lollards who made extraordinary pretences to piety and religion, and spent the greater part of their time in meditation, prayer, and such acts of piety, there were many abominable hypocrites, who entertained the most ridiculous opinions, and concealed the most enormous vices under the specious mark of this extraordinary profession.

Many injurious aspersions were propagated by the priests and monks against those who assumed this name; so that, by degrees, any person who covered heresy or crime under the appearance of piety was called a *Lollard*. Thus the name was used not to denote any one particular sect, but was formerly common to all persons and all sects who were supposed to be guilty of impiety towards God or the church, under an external profession of extraordinary piety. However, many societies, consisting both of men and women, under the denomination of *Lollards*, were formed in most parts of Germany and Flanders, and were supported partly by their manual labours, and partly by the charitable donations of pious persons. The magistrates and inhabitants of the towns where these brethren and sisters resided, gave them particular marks of favour and protection, on account of their great usefulness to the sick and needy. They were thus supported against their malignant rivals, and obtained many papal constitutions, by which their institute was confirmed, their persons exempted from the cognizance of the inquisitors, and subjected entirely to the jurisdiction of the bishops; but as these measures were insufficient to secure them from molestation, Charles duke of Burgundy, in the year 1472, obtained a solemn bull from Sixtus IV. ordaining that the Cellites or Lollards should be ranked amongst the religious orders, and delivered from the jurisdiction of the bishops; and in the year 1506 Julius II. granted them still greater privileges. Mosheim informs us that many societies of this kind still subsisted at Cologne, and in the cities of Flanders, though they had evidently departed from their ancient rules.

Lollard and his followers rejected the sacrifice of the mass, extreme unction, and penances for sin; arguing that Christ's sufferings were all-sufficient. He is likewise said to have set aside baptism, as a thing of no effect; and repentance, as not absolutely necessary. In England, the followers of Wickliffe were by way of reproach called Lollards, from the affinity there existed between some of their tenets and those of that sect; though others are of opinion that the English Lollards came from Germany. The Lollards were solemnly condemned by the archbishop of Canterbury and the council of Oxford.

LOMBARD, PETER, well known by the title of *Master of the Sentences*, was born at Novara, in Lombardy; but being bred at Paris, he distinguished himself so much at that university, that he had conferred on him the canonry of Chartres, was for some time tutor to Philip son of Louis le Gros, and lastly obtained the see of Paris. He died in 1064. His work of the *Sentences* is regarded as the source of the scholastic theology of the Latin church. He also wrote Commentaries upon the Psalms, and upon St Paul's Epistles.

LOMBARDS, a northern nation, who settled in Italy in the fourth century, and for some time made a considerable figure.

The name of *Lombards*, or *Longobards*, is by some derived from the word *lack*, or *lache*, signifying in the German tongue *winter*, because the Lombards, whilst in Seandinavia, lived in marshes, or near to the sea; whilst others think that it comes from the two German words *langen harden*, or *helleborden*, that is, from the long halberts they were supposed to use in war. But Paulus Diaconus their historian, and who was himself a Lombard, tells us that they were called *Longobards*, from the length of their beards. A nation called *Lombards* is mentioned by Tacitus, Strabo, and Ptolemy; but these are different from the Lombards who afterwards settled in Italy, and are reckoned the same with the Gepidæ, whom the Italian Lombards almost exterminated. The Lombards who settled in Italy are first mentioned by Prosper Aquitanus, bishop of Rhegium in the year 379. That writer tells us, that about the time referred to, the Lombards, abandoning the distant coasts of the ocean, and their native country Scandinavia, and seeking for new settlements, as they were overstocked with people at home, first attacked and overcame the Vandals in Germany. They were then headed by two chiefs, Iboreus and Aion, who, having died about the year 389, were succeeded by Agilmund, who is commonly reckoned the first king of the Lombards.

Before the time of Odoacer, Lombard history presents nothing very remarkable; in his time, however, they settled on the Danube, in the country of the Rugians, whom Odoacer had almost totally exterminated or carried into captivity. During their stay in this country, they rendered themselves formidable to the neighbouring nations, and carried on successful wars with the Heruli and Gepidæ. In 526 they were allowed by the Emperor Justinian to settle in Pannonia; and here they made war a second time with the Gepidæ. Alboin, the Lombard king, killed the king of the Gepidæ with his own hand, put his army to the route, and cut in pieces such numbers of them, that they ceased from that time to be a nation. Having caused the deceased king's head to be cut off, he made a cup of his skull, called in the language of the Lombards *schala*, which he made use of in all public entertainments. However, having, amongst many other captives of great distinction, taken the last king's daughter, by name Rosamunda, he married her after the death of his former wife Clodisvinta, the daughter of Clothaire king of France.

By this victory Alboin gained such reputation that his friendship was courted by Justinian; and, in consequence of the emperor's application, a body of six thousand Lombards was sent to the assistance of Narses against the Goths. The success of the Romans in this expedition, the invasion of Italy by the Lombards, and their successes in that country, have been noticed under the article ITALY. At last, Alboin having made himself master of Venetia, Liguria, Æmilia, Etruria, and Umbria, was slain by the treachery of his wife, in the year 575, being the fourth of his reign. This princess was the daughter of the king of the Gepidæ, whom Alboin had killed in battle, and made a cup of his skull, as above related. As he was one day feasting at Verona, with his chief favourites and principal officers, in the height of his mirth he sent for the queen, and, filling the detested cup, he commanded her to drink merrily with her father. Rosamund, struck with horror, hurried out of the room; and, highly incensed against her husband for thus barbarously triumphing over the misfortunes of her family, resolved, at all events, to make him pay dear for his inhuman and insulting conduct. She discovered her intention to Helmichild the king's shield-bearer, a youth of great boldness and intrepidity; but he peremptorily refused to imbrue his hands in the blood of his sovereign, or to be in any way accessory to his death; and in this resolution he persisted, until, by a shameful stratagem, forced to comply with the queen's wishes. Knowing that he carried on an intrigue with one of her ladies, Rosamund placed herself one night in that lady's bed, and receiving the youth, indulged him in his amorous desires, as if she had been his own mistress. Then discovering herself to the deceived lover, she told him that he must now either put the king to death, or be put to death by him. Helmichild, well apprised that, after what he had done, his safety depended upon the death of the king, engaged in the treason, which he otherwise abhorred. One day, therefore, whilst Alboin was reposing in his chamber after dinner, Helmichild, with some others whom he had made privy to his design, broke in unexpectedly, and fell upon the king with their daggers. Alboin started up and laid hold of his sword, which he had always by him; but having in vain attempted to draw it, the queen having beforehand fastened it in the scabbard, he defended himself for some time with a footstool. In the end, however, he was overpowered, and despatched with many wounds.

Rosamund had promised to Helmichild, that, as soon as he had despatched the king she would marry him, and, with her person, bestow upon him the kingdom of the Lombards. The first part of her promise she immediately performed; but she was so far from being able to bestow the crown upon him, that both of them were obliged to save themselves by flight. They fled to Longinus the exarch of Ravenna, taking with them all the jewels and treasure of the late king. Longinus received her with the greatest marks of friendship and kindness, and assured her of his protection. But she had not been long in Ravenna, before the exarch, thinking that a favourable opportunity now offered for making himself king of Italy by her means, imparted his design to her, and declared his intention to marry her, provided, by some means or other, she despatched Helmichild. Rosamund, highly pleased with the proposal, resolved to satisfy her ambition by getting rid of the person whom she had only married in order to gratify her revenge. Accordingly, having prepared a strong poison, and mixed it with wine, she gave it to her husband as he came out of the bath, and called for drink, according to his custom. Helmichild had not half emptied the cup, when, by the sudden and strange sensation which he felt in his bowels, he concluded what it was; and, with his sword pointed at the queen's breast, compelled her to drink the rest. The poison had the same effect on both, for they died in a few hours. Longinus, on the death of the queen, laid aside all thoughts of making himself king of Italy, and sent the king's treasure to Constantinople, together with Albisoinda, the daughter of Alboin by Rosamund, whom she had brought along with her.

After the death of Alboin, the Lombards chose Clephis, one of the nobility, as their king. But he was murdered after a short reign of eighteen months; upon which ensued an interregnum of ten years. During this time, they extended their conquests in that country; but at length the Romans, jealous of their progress, resolved to put a stop to their victories, and, if possible, to expel them from the country. For this purpose, they entered into an alliance with the Franks; which so alarmed the Lombards that they re-established the monarchical form of government amongst themselves, and chose Autharis the son of Clephis as their king. This monarch, considering that the power of the dukes, who had governed Lombardy for the space of ten years, was during that time tolerably well established, and that they would not probably be willing to part with the authority which they had so long enjoyed, allowed them to continue in their government, but obliged them to contribute one moiety of their revenues towards the maintenance and support of his royal dignity, suffering them to dispose of the other as they thought proper. He reserved to himself the supreme dominion and authority, and took an oath from the dukes, that in time of war they would readily assist him to the utmost of their power. Though he could remove the dukes at pleasure, yet he deprived none of them of their dukedoms, excepting in cases of treason, nor gave them to others, except when their male issue failed. Having settled matters in this manner, he enacted several very wholesome laws against theft, rapine, murder, adultery, and other vices which prevailed amongst his subjects, and was the first of the Lombard kings who embraced Christianity. Most of his subjects followed the example of their monarch; but as they were all instructed by Arian bishops, they continued long infected with that heresy, which occasioned great disputes between them and the orthodox bishops of the cities subject to their sway.

From the re-establishment of the monarchy under Au tharis, until the reign of Rotharis in 636, the history of the Lombards affords nothing memorable.[*] This period is remarkable for the introduction of written laws amongst the Lombards. Before his time they had been governed only by tradition; but Rotharis, in imitation of the Romans and Goths, undertook the publication of written laws; and to those which he enacted many were added by succeeding princes. Grotius prefers the method which the Lombards followed in making laws, to that which was practised by the Romans themselves. Amongst the latter the emperor was the sole lawgiver; and whatsoever he decreed had the force of a law. But the Lombard kings did not assume that power to themselves, since their laws were enacted in public assemblies convened for the purpose, after they had been maturely examined and approved of by all the lords of the kingdom. From these assemblies were excluded the ecclesiastical order, and the people; so that the legislative power was lodged exclusively in the king and the nobles.

The reign of Rotharis is remarkable, not only for his introducing written laws amongst his subjects, but for the conquests which he made, and the successful wars which he carried on with the exarch of Ravenna, whom he totally defeated in several engagements, at the same time making himself master of some part of his territories. This monarch died in 652; and the affairs of the Lombards went on prosperously, till the ambition of Luitprand laid the foundation of the total ruin of his kingdom. He ascended the throne of Lombardy in 711, and watched every opportunity of enlarging his dominions at the expense of the emperor. For this a fair occasion offered in 716. The Emperor Leo Isauricus, who at that time reigned in the East, having, by his famous edict, forbidden the worship of images, and ordered them to be everywhere pulled down, the people were so incensed at that innovation, that, in several places, they openly revolted, and, falling upon the emperor's officers, drove them out of the cities. In the East, Germanus, the patriarch of Constantinople, opposed the emperor's design with great warmth; but Leo caused him to be deposed, and Anastasius to be raised to that see in his room, at the same time ordering that all the images in the imperial city should be pulled down and publicly burned. He strictly enjoined his officers in the West, especially the exarch of Ravenna, to see his edict punctually obeyed in their respective governments. In compliance with these orders, Scholasticus, then exarch, began to pull down the images in all the churches and public places in Ravenna; a proceeding which incensed the superstitious multitude to such a degree, that, taking arms, they openly declared that they would rather renounce their allegiance to the emperor than give up the worship of images.

A kind of civil war being thus kindled in the city, Luitprand thought he had now a favourable opportunity of making himself master of the seat of the exarch, not doubting but the conquest of such an important place would be followed by that of the whole exarchate. Having therefore drawn together all his forces, he unexpectedly appeared before Ravenna, which he closely besieged. The exarch had little expected such a surprise, a friendly correspondence having been maintained for many years between the exarchs and the Lombard kings. However, he defended the place with such courage and resolution, that Luitprand, despairing of success, raised the siege, and led his army against Classis, at a small distance from Ravenna, which he took, plundered, and levelled with the ground. The loss of this place, and the severe treatment which the inhabitants met with from the king, threw the citizens of Ravenna into the utmost consternation. Informed of this, Luitprand resolved to take advantage of their fears, and, returning before Ravenna whilst the inhabitants were thus disheartened, to attempt once more the reduction of the place. Accordingly he led his whole army against it, and, by frequent attacks, tired the inhabitants and garrison to such a degree, that the exarch, finding they could hold out no longer, and despairing of relief, withdrew privately. Luitprand, informed of his retreat, attacked the town with more violence than ever; and, having carried it by storm, gave it up to be plundered by his soldiers, who found in it an immense booty. The king stripped it of most of its valuable monuments of antiquity, and, amongst the rest, caused an equestrian statue of an emperor, of wonderful workmanship, to be conveyed to Pavia, where it is to be seen to this day. The reduction of Ravenna was followed by the surrender of several cities of the exarchate, which Luitprand reduced to a dukedom, appointing Hildebrand his grandson to govern it with the title of duke, and giving him, as he was yet an infant, Peredeus duke of Vicenza as his guardian.

The conquest of Ravenna and the greater part of the exarchate alarmed Gregory II. bishop of Rome. He was then at variance with the emperor, whose edict against the worship of images he had opposed with all his might, and thereby provoked Leo to such a degree that he had threatened to drive him from the see, and send him into exile. However, the pope, no less jealous of the power of the Lombards than all his predecessors had been, resolved, by some means or other, to put a stop to their conquests. The only prince in Italy to whom he could have recourse, was Ursus duke of Venice. To him accordingly he wrote a very pressing letter, conjuring him to assist his worthy son the exarch, and, for the love of the holy faith, to attempt with him the recovery of the exarchate, which the wicked nation of the Lombards had unjustly taken from his sons Leo and Constantine, emperors. Ursus and the Venetians, moved with the pope's letter, and at the same time alarmed at the growth of so powerful a neighbour, promised to assist the exarch with the whole strength of the republic; and accordingly fitted out a considerable fleet, pretending that it was designed for the service of the emperor against the Saracens. At the same time the exarch, who had taken refuge in Venice, abandoning that place as it were in despair of bringing the duke over to his party, raised, in the places still subject to the emperor, what forces he could; and having got together a considerable body, he marched with them towards Imola, giving out that he designed to besiege that city; but turning on a sudden towards Ravenna, as had been agreed upon between him and the Venetians, he laid siege to that city by land, whilst almost at the same instant they invested it by sea. Peredeus defended the town for some time with great courage and resolution, obliging all those who were able to bear arms to repair to the walls. But the Venetians having, in spite of all opposition, forced open one of the gates on the seaward face, the city was taken, and Peredeus slain, whilst he was attempting, at the head of a chosen body, to drive the enemy from the posts they had seized. As for Hildebrand, he fell into the hands of the Venetians, who, having thus recovered Ravenna to the emperor, returned home, leaving the exarch in possession of the city. Luitprand was then at Pavia; but the town was taken before he could assemble troops to relieve it.

Gregory, bishop of Rome, to whom the recovery of Ravenna was chiefly owing, having persuaded himself that the emperor would, out of gratitude, give ear to his remonstrances and admonitions, began to solicit him more pressingly than ever to revoke his edict against the worship of images; but Leo, apprised that the bishop, in all the measures he had taken, had been more influenced by a regard to his own interest than to that of the empire, instead of listening to his remonstrances, was still more provoked against him for thus obstinately opposing the execution of his edict. Being therefore resolved at all events to cause it to be observed in Rome itself, and, on the other hand, not doubting but the pope would oppose it to the last, in order to remove all obstacles, he sent three officers to Rome, with private orders, either to despatch the pope, or to take him prisoner and convey him to Constantinople. At the same time, he wrote to Mauritius, duke of Rome, secretly enjoining him to assist his officers in their undertaking; but no favourable opportunity having offered to put their design in execution, the emperor, in the year 725, recalled Scholasticus, and sent Paul, a patrician, into Italy, to govern in his stead, with private instructions to encourage the officers already mentioned with the promise of great rewards, and to assure them of his protection.

But, in the mean time, the plot was discovered, and two of the conspirators having been apprehended by the citizens of Rome, were put to death; the third escaped into a monastery, where he took the monastic habit, and ended his days. Hereupon the exarch, in compliance with the emperor's orders, resolved to proceed no longer by secret plots, but by open force. Accordingly he drew together a considerable body of troops, and set out at their head, on his march to Rome, with the design of seizing the pope, and sending him, as he had engaged to do, in chains to Constantinople. But, on this occasion, Luitprand, though highly provoked against Gregory for having stirred up the Venetians against him, resolved to assist him and the citizens of Rome against the exarch, in order to keep the balance even between them, and, by aiding sometimes the one, and sometimes the other, to weaken both. Pursuant to this resolution, he ordered the Lombards of Tuscany, and those of the dukedom of Spoletto, to join the pope and the inhabitants of Rome, who being by this reinforcement far superior in strength and number to the exarch, obliged him to return to Ravenna, and give over all thoughts of any further attempt on the person of the pope.

In the mean time, Leo, persisting in his former resolution of suppressing throughout his dominions the worship of images, sent fresh orders to the exarch Paul, strictly enjoining him to cause his edict to be put in execution in all the cities of Italy, especially in Rome. At the same time, he wrote to the pope, promising him his favour and protection, if he complied with the edict; and declaring him, if he continued to oppose it, a rebel, and no longer invested with the papal dignity. But Gregory was so far from yielding to the emperor's threats or promises, that, on the contrary, he solemnly excommunicated the exarch for attempting to put the imperial edict in execution, and at the same time wrote circular letters to the Venetians, to King Luitprand, to the Lombard dukes, and to all the chief cities of the empire, exhorting them to continue stedfast in the Catholic faith, and to oppose with all their might such a detestable innovation. These letters made such an impression on the minds of the people in Italy, that though of different interests, and often at war with one another, they all united, protesting they would defend the Catholic faith, and the life of the pope, in so glorious a cause, at the expense of their own; nay, the citizens of Rome, and the inhabitants of Pentapolis, now the March of Ancona, not content with such a protestation, openly revolted against the emperor, and pulling down the statues, elected, by their own authority, magistrates to govern them during the interregnum. We are even told, that, transported with a blind zeal, they were for choosing a new emperor, and conducting him to Constantinople, not doubting that the people would everywhere join them. But the pope, thinking this resolution unseasonable and impracticable, opposed it.

In the mean time, the exarch Paul, having gained a considerable party in Ravenna, began, pursuant to the repeated orders from the emperor, to remove the images, as so many idols, out of the churches. Hereupon the adverse party, supported and encouraged by the pope, flew to arms, and, falling upon the *iconoclasts*, or image-breakers, as they styled them, raised a civil war within the walls of Ravenna. Great numbers were killed upon both sides; but those who were for the worship of images prevailed in the end; a dreadful slaughter was made of the opposite party; and, amongst the rest, the exarch himself was murdered. However, the city of Ravenna continued faithful to the emperor; but most of the citizens of Romagna belonging to the exarchate, and all those of Pentapolis or the March of Ancona, abhorring the emperor as an heretic, submitted to Luitprand, king of the Lombards, who, pretending a zeal for the Catholic religion, took care to improve the discontent of the people to his advantage, by representing to them that they could never maintain their religious rights under a prince who was not only an heretic, but a persecutor of the faithful.

In Naples, Exhilaratus, duke of that city, having received peremptory orders from the emperor to cause his edict to be put in execution, did all that lay in his power to persuade the people to receive it; but finding his endeavours thwarted by the bishop of Rome, for whom the Neapolitans had a great veneration, he hired assassins to murder the pontiff. But the plot being discovered, though carried on with great secrecy, the Neapolitans, highly provoked against the duke, tore both him and his son to pieces, and likewise put to death one of his chief officers, who had composed a libel against the pope. Luitprand, and Gregory, at that time Duke of Benevento, laying hold of so favourable an opportunity to make themselves masters of the dukedom of Naples, did all in their power to persuade the Neapolitans to submit to them. But the Neapolitans, bearing an irreconcilable hatred to the Lombards, with whom they had been constantly at variance, rejected every overture of that kind with the utmost indignation; and continuing stedfast in their allegiance to Leo, received from Constantinople one Peter, who was sent to govern them in the room of Exhilaratus. Some writers suppose that the Neapolitans, in this general revolt of the cities of Italy, had shaken off the yoke along with the rest, and appointed magistrates of their own election to govern them, in the room of the officers hitherto sent from Constantinople, or named by the exarch. But they are certainly mistaken; for it is manifest from history that Peter succeeded Exhilaratus in that dukedom, and that the Neapolitans continued to live under the emperors until they were conquered many years afterwards by the Normans.

In the mean time, Leo, hearing of the murder of the exarch, and the general revolt of the cities, and not doubting that the pope was the chief author of so much mischief, sent the eunuch Eutychius into Italy, with the title and authority of exarch, strictly enjoining him to get the pope despatched by some means or other, since his death was absolutely necessary for the tranquillity of Italy. The exarch spared no pains to get the pope into his power. But a messenger, whom he had sent to Rome, being apprehended by the citizens, and an order from the emperor being found upon him to the imperial officers in that city, commanding them to put the pope to death at all events, the pontiff's friends thenceforth guarded him with such care, that the exarch's emissaries could never afterwards find an opportunity of executing their design. As for the messenger, the Romans were for putting him to death; but the pope interposed to save him, and contented himself with excommunicating the exarch.

And now the Romans, provoked more than ever against Leo, and, on the other hand, unwilling to live under the Lombards, resolved to revolt against the emperor, and appoint their own magistrates, keeping themselves united under the pope, not as their prince, but only as their head. This they did accordingly; and from these slender beginnings the sovereignty of the popes in Italy took its rise, though the pontiffs did not then, as is commonly supposed by historians, become sovereign lords of Rome, but many years afterwards.

Eutychius failed in his design upon the life of the pope; but having brought with him from Constantinople a good number of troops, he easily quelled the rebellion in Ravenna, and severely punished the authors of the late disturbances. As for the rebellious Romans, he was well apprized that he could never reduce them, as long as they were supported by the king of the Lombards; and therefore he employed all his art and policy to detach that prince from the party of the Romans, and to bring him over to his own interest.

Luitprand for some time withstood all his offers; but Thrasimund, duke of Spoletto, having revolted at that juncture, the exarch, taking advantage of the opportunity which presented itself, offered to assist the king with all his means against the rebellious duke, provided he would, in like manner, assist him against the pope and the Romans. With this proposal Luitprand readily closed; and a league being concluded upon these terms, between him and the exarch, the two armies joined, and began their march towards Spoletto. At their approach, the duke, despairing of being able to resist two such powers, came out with a small attendance to meet them, and, throwing himself at the king's feet, sued, in that humble posture, for pardon; which Luitprand not only granted him, but confirmed him in the dukedom, after he had obliged him to take a new oath of allegiance, and to give hostages for his fidelity in time to come. From Spoletto, the two armies marched, in pursuance of the treaty, to Rome, and encamped in the meadows of Nero, between the Tiber and the Vatican.

Gregory had caused the city of Rome to be fortified in the best manner he could; but being sensible that the Romans alone could not long hold out against two such armies, and reflecting on the kind treatment the duke of Spoletto had met with upon his submitting to the king, he resolved to follow his example; and accordingly, taking with him some of the clergy, and the principal inhabitants of the city, he went to wait upon the king in his camp, where, by a pathetic speech, he softened Luitprand to such a degree, that throwing himself at his feet, in the presence of the whole army, he begged pardon for entering into an alliance against him, and, assuring him of his protection for the future, he went with them to the church of St Peter, where, disarming himself in the presence of his principal officers, he laid his girdle, his sword, and his gauntlet, with his royal mantle, his crown of gold, and cross of silver, on the apostle's sepulchre. After this, he reconciled the pope with the exarch, who was thereupon received into the city, where he continued for some time, maintaining a friendly correspondence with the pope. At this time an impostor, taking the name of Tiberius, and pretending to be descended from the emperors, seduced a great many people in Tuscany, and was by them proclaimed emperor. The exarch resolved to march against him; but as he had not sufficient forces to oppose the rebels, Gregory, who let slip no opportunity of obliging Leo, persuaded the Romans to attend the exarch in this expedition, by which means the usurper was taken in a castle, his head sent to the emperor, and the rebellion utterly suppressed. But the emperor still insisting upon his edict against the images being received in Rome, the Romans, at the instigation of the pope, publicly renounced their allegiance to Leo, paid him no more tribute, and withdrew for ever their obedience to the emperors of the East.

Leo, informed of this revolt, and not questioning that the pope was the author of it, immediately caused all the patrimony of the church of Rome in Sicily, Calabria, and his other dominions, to be confiscated. At the same time he ordered a powerful army to be raised, with the design of recovering the towns which had revolted, chastising the Romans for their rebellion, and, above all, being revenged on the pope, who had raised these disturbances, by himself opposing, and persuading others to oppose, the execution of his edict. Gregory, alarmed at the warlike preparations which were making throughout the empire, and well apprised that they were chiefly designed against himself and the Romans, resolved to recur to the protection of the French, the only nation at that time capable of coping with the emperor, and upon whom, on account of their zeal for religion, he thought he might depend. The Lombards were then very powerful; but, as they wanted to be masters of Rome, he did not think it advisable to trust them. The Venetians, though zealous in the defence of the pope, were not yet in a condition to withstand the power of the emperor, and, besides, were jealous of the Lombards, who watched all opportunities of enlarging their dominions at the expense of their neighbours. As for Spain, it was then in a deplorable condition, being overrun, and almost wholly ruined, by the Saracens.

The French nation was at this time governed by the celebrated Charles Martel, who had distinguished himself in an eminent degree in the wars of France and Germany; and having, not long before, gained a signal victory over the Saracens in the neighbourhood of Tours, he was generally reputed the best commander, and the greatest hero, of his time. To him, therefore, Gregory sent a solemn embassy, with a great number of relics, earnestly entreating him to take the Romans, and the church, under his protection, and to defend them against the attempts of Leo. The ambassadors were received with extraordinary marks of honour, and a treaty was soon concluded between them and Charles, who engaged to march into Italy in person, at the head of a powerful army, in defence of the Romans and the church, if they should be attacked either by the emperor or the Lombards. On the other hand, the Romans were bound to acknowledge him as their protector, and to confer upon him the honour of the consulship, as it had been formerly conferred on Clovis by the Emperor Anastasius, after that prince had defeated the Visigoths. The ambassadors returned from France loaded with rich presents. But Gregory did not long enjoy the fruit of their negociations; for he died the same year, 731, and was succeeded by Gregory III., in whose time some have placed the embassy here mentioned.

At this time the French nation had just recovered from its distressed situation under the descendants of Clovis; and, by the bravery and conduct of Charles Martel, it had become the most powerful kingdom in the west. His successor Pepin was no less wise and powerful than his father had been; and as the ambition of the Lombard princes would be satisfied with nothing less than the entire conquest of Italy, the French monarch, Charlemagne, under colour of assisting the pope, at last put an end to the empire of Lombardy.

LOMBARDY.

This interesting part of Italy was in remote periods thinly inhabited, till in the sixth century it formed a kingdom. As the history of Lombardy is in this work included in the general history of Italy, we must refer to that article in its alphabetical order, where may be traced the manner and period by which it became the territory of the house of Austria.

In its present state it is distinguished by the name of the kingdom of Venetian Lombardy, which was conferred on it by the treaties of Vienna in 1815. It is a compact territory, bounded on the north by Switzerland and the Tyrol, on the east by Illyria and the Adriatic Sea, on the south by the States of the Church and the duchies of Modena and Parma, and a part of the kingdom of Sardinia, and on the west by Sardinia. It extends over 18,744 square miles, and contains 4,217,650 inhabitants, all of them adhering to the Roman Catholic church.

The far greater part of this kingdom is a level plain, bounded on the north by the Rhætian Alps, and on the south by the river Po, into which most of the numerous rivers and rivulets empty themselves. The whole valley declines towards the south, but so gently, that the fall of water in that river, from its source to its mouth, is not more than 190 feet; and the smaller streams are equally languid. The soil is generally light, but fertile, on a basis of calcareous subsoil, except that at the foot of the mountains there are some portions of sandy heaths, and on the coast, where the great rivers discharge their waters, the land is marshy, and formed into extensive lagunes. In the mountainous northern border the land is frequently stony, but even there the soil which covers the valleys is a vegetable mould of a greater or less degree of fertility.

The mountains which form the southern boundary, and which are within the kingdom, are a portion of the Alps, beginning on the north side of the lake of Como, and extending between it and Switzerland to the Tyrol. The valley of the Valteline is enclosed by them; and the loftiest points are, the Splugen, 8130; the Legnone, on the lake of Como, 8130; the Godena, 7459; the Tremezzo, 5106; and the Corno de Canza, 4260 feet in height. Some of the mountains on the frontier towards the Tyrol are still higher, but have this difference, that they are not at all seasons bound in frost. Towards the east these ranges of mountains are joined with those of Carinthia. Amongst all these extensive elevations are to be found valleys of greater or less extent, but of high fertility, and presenting the most exciting prospects.

The Po, the greatest of the Lombardy rivers, has a course of near 200 miles; and, though languid in its current, is so filled, generally in the spring, as to cause extensive inundations on both its banks. In its progress it receives the waters of the Ticino, which rises near Mount St Gothard, and joins the Po near Pavia. The other streams which contribute to this great river are, the Olona, the Lambro, the Adda, the Oglio, and the Mincio. The next great river is the Adige or Etsch, which rises in the Tyrol, passes through two lakes near to Botzen, where it receives the Eisach, when it becomes navigable and enters Lombardy, and then, passing by Rivoli, empties itself into the Adriatic Sea at Brendola. In its progress it is augmented by the waters of the Brenta, the Bachiglione, the Piave, the Livinza, the Lemone, and the Tagliamento, all of which are navigable.

In Lombardy there are two descriptions of lakes, those of fresh water amongst the mountains, and those of salt water in the level country on the borders of the Adriatic. Of the former, the most remarkable for extent, and for the picturesque scenery on the banks, are the following: 1*st*, Lago Maggiore. It begins in the Swiss canton of Ticino, and extends into the boundaries of Lombardy and of Sardinia to Sesto. It is formed by the river Ticino and twenty-six smaller streams, is about forty-eight miles in length, from four and a half to seven in breadth, varying considerably, and generally from twenty-four to thirty feet deep. It is connected by the river Tresa with the lake of Lugano, and is 750 feet above the level of the sea. 2*d*, Lago Lugano. This is also on the frontiers of Switzerland, is 870 feet above the level of the sea, and is fed by forty-three brooks and rivers, entering it from the Austrian dominions. 3*d*, Lago di Como. This is formed by the river Maixa, near Cordona, and is divided on the southern part into two arms or branches. Its elevation above the sea is about 700 feet; the greatest length is thirty-seven miles, and its breadth varies from one and a quarter to four miles. It is plentifully stocked with fish; the banks are studded with farms and villages, whilst the lofty mountains form a most picturesque background to the scenery. The river Adda receives from it several of its tributary streams. 4*th*, Lago d'Iseo. This lake, near the foot of the mountains, is about twenty miles in length, and in breadth varying from four and a half to seven miles. 5*th*, Lago d'Idro, which is only about seven miles in length. 6*th*, Lago di Garda, or, as it is still sometimes called by the ancient name, Lake of Benaco. It is one of the most beautiful of the lakes of Lombardy, is about thirty-five miles in length, varying in breadth from four to fourteen miles, and in depth from ten to 300 feet. It is chiefly fed by the river Sarca, and a discharge of its water near Peschiera forms the river Mincio. It was the subject of the panegyrics of Virgil and Catullus; and has been rendered celebrated by the victories of Bonaparte over Wurmser in the year 1796.

The lagunes are formed by the rivers which descend from the Alps, and spread along the shores of the Adriatic; they are defended from the sea by steep artificial walls, not unlike the dykes in Holland, which in some degree prevent the influence of the rise and fall of the tides; but in some cases, where the force of the sea has broken through, harbours have been formed. Of such havens, there are four large ones, viz. Malamoco, Santa Nicolo, Chioggio, and Tre-Porti; and two inconsiderable, viz. Lido Maggiore and St Erasmo.

There are mineral springs of various degrees of efficacy and reputation for medicinal purposes. The most remarkable of them are at Worms and Massimo in the Valteline, at Albano in the delegation of Padua, at Caldiero near Verona, at Recoaro in the province of Vicenza, at Trescoria and St Pelegrino in the delegation of Bergamo, and Cenedo and Piano in that of Treviso. The climate is very mild, except on the border mountains. On the plains the snow scarcely ever remains on the ground, and it is rare that ice is found in the still lagunes near Venice. What falls from the heavens in winter is much more common in the form of rain than of hail or snow. The winter scarcely lasts more than two months; and in February the fields are covered with new grass. In May the hot weather begins, and the harvest is secured in June and July. In September and October the annual labours of the vintage are performed.

The climate, on the whole, may be described as healthy; but from that description must be excluded those parts where rice is extensively cultivated, as well as the vicinity of Mantua, and the marshy districts extending from Venice to Rovigia, and beyond it. In the latter, sickness is marked in the complexions of the inhabitants; and numbers of the people from the Apennines, or of Illyrian peasants, a hardy race, who descend from their lofty homes to gather the harvest, fall victims to the marsh fevers.

As Lombardy is the most densely peopled, so it is the best cultivated, district in Europe. In no other part is the benefit of irrigation more clearly understood, or more accurately appreciated; and the practical application of it becomes in some measure a substitute for that animal manure which is more abundantly supplied in the other most productive portions of the earth. Although, from the nature of the climate and the habits of the people, a larger quantity of leguminous vegetables are used for aliment than of bread and flesh, yet abundance of corn is annually raised. Wheat, barley, and oats are grown, but not extensively; and rye is to be found very rarely, excepting in the delegation of Friouli; but, on the other hand, rice is grown to a great extent, insomuch that the government has attempted to check its further extension. As the wealth and prosperity of Lombardy, and in fact of the whole of Italy, is derived chiefly from the productions of the soil, an extended view of its agriculture must be of much importance; and we enter upon the subject here, because, in the description of the agriculture of the other parts of Italy, it will only be necessary, in the progress of this work, to refer generally to the practices of Lombardy, and to point out the few differences that may exist.

The importance of irrigation is more felt, and the practice of it more extended, in Lombardy, than in any other part of Europe. This depends much on the physical circumstances of the country, but has also in a great measure arisen from the skill of the people, who, by long practice in the art of conducting water, have acquired the habit of leading it to the parts where it may be applied with the greatest success.

Two of the reservoirs that supply water for the purpose of irrigation, viz. Lago Maggiore and Lago di Lugano, are only in part within the Austrian territory; but the waters they discharge enter that part of Italy, and become available within it for both the purposes of internal navigation and of irrigation. The lakes of Como and of Garda, and several of smaller extent, are wholly within the boundaries of Lombardy. All of them are vast deposits of water, chiefly formed by the rapid streams issuing from the frozen ice and snow of the Alps, and in part by springs, which abound near the foot of those lofty elevations. They are scarcely ever frozen, and never to so intense a degree as wholly to suspend the course of the streams which issue from them, and so powerfully tend to fertilize the land through which they pass in their progress towards the Po.

The lake of Como and Lago Maggiore are about 700 feet above the level of the sea; and that of Garda, whose termination is nearer the Po, is 150 feet above it. As the Po is a river of many sinuosities, by which its course to the sea is much elongated, the river Ticino, from Lago Maggiore, which joins the Po a little below Pavia, is calculated at that point to be about 300 feet above the level of the Adriatic, and, through the stream of the Po, with many curves, is at length lost in the sea.

The plains of Lombardy, then, may be considered as a gentle slope, looking to the south, and bounded in that quarter by the Po. If the average distance from the foot of the mountains, where the lakes have been formed, to the Po, be computed at sixty miles, and the points where the rivers fall into it at 300 feet lower, we may assume that the slope of the plain is at the rate of about five feet in the mile. Such a rate of declination cannot be accurate, but it is a sufficient approximation to accuracy to give an idea of the facility with which irrigation may be performed. Though this representation of the gradual sloping of the face of the country may be generally applicable to it, yet many exceptions must be allowed for. Between the courses of the various streams are numerous elevations, though none of them lofty, which are too high to be susceptible of being irrigated by the great rivers; but in many instances such spots are benefited by being near to springs or brooks, which the long acquaintance of the natives with the practices of irrigation leads them to apply in a greater or less degree to that purpose. Near to the principal streams which convey these collected waters to the sea, there are portions of land so low as to be liable to such abundant overflowings, that they can only be for a time left with a surface sufficiently dry to admit of cultivation for rice; and the vicinity of such lands is injurious to human life, whilst those fields which can, at the will of the occupier, be left either dry, or watered with streams in motion, are not known to be less salubrious than those on the hills near them.

The facilities for irrigation in the best districts have been much increased by the construction of canals, which, whilst they serve the purpose of inland navigation, are made use of to convey streams of water over the fields, which pass from the property of one proprietor to that of another, till they enter again the canals at a lower level. Some of these canals are the work of remote ages. The most ancient, as well as the most considerable, of these, is the *Naviglio Grande*, which was opened in the year 1270. The water is conveyed to the Ticino, near Tornavento, and proceeds to Abbiategrasso, a distance of eighteen miles, where it divides into two branches. One of these is conducted to Beneguardo, eleven miles, and the other to Milan, fourteen miles, thus making a line of forty-three English miles. This great undertaking was commenced after the death of Charlemagne, just as the cities of Lombardy began to be constituted independent states, about the year 1177, and in a few years was executed to Abbiategrasso. It was extended to Milan by 1257, but was then only adapted to the purpose of irrigation. It was next widened, and thus rendered navigable, at the expense of the city of Milan, which, within that period, had become the capital of a rich dukedom; and, by the water communication it thus obtained, flourished in a great degree from its commerce, as well as from the rich fields which the waters had rendered highly productive.

It would be needless to record the progress of the other canals which have since been constructed, or to enumerate them. It may not, however, be improper to notice the last of these great and beneficial works. It is known as *Nuovo Naviglio di Pavia*, and passes from Milan to Pavia, through Benasco, and there falls into the Adda, a little above the junction of that river with the Po. This undertaking was begun in 1814, and completed in 1819. The quantity of goods conveyed by it, and the quantity of water supplied by it to the neighbouring fields, have secured a large profit to the operators, and conferred a great additional value on the lands in its vicinity.

An ancient law of Lombardy has contributed, from the most remote period, to the extension of the distribution of water. The whole of that substance was the property of the sovereign. An individual, or a corporate body, might purchase the water, and thereby acquire the right to conduct it by canals in any direction, and there to sell it to the cultivators. But they could not carry it through gardens or pleasure-grounds, and were bound to pay the owners of the land the value of that portion which was made use of for the passage of the water. In process of time the right of the sovereign over the water was ceded to those who became the purchasers thereof, and was at length extended to those who had springs on their ground, or should afterwards discover any. One instance recently occurred of the exercise of this right. An individual found a spring on a small piece of ground, seventeen miles from the main bulk of his property, and conducted the water from one to the other over the lands of a vast number of proprietors. Though, as all judicious people foresaw, he ruined himself by the operation, instead of making money by selling his water near the spring, as he might have done, yet the law proceedings which arose confirmed the right.

The value of water in Lombardy is best seen by a comparison of the rent paid for land of the same quality, according to the power of obtaining irrigation. Dry meadows will let at from 24s. to 40s. per English acre, and that so situated as to be accessible to water is eagerly rented at from 48s. to 160s. per acre, according to its greater or less capability of obtaining water.

The purchase and sale of water is a traffic of much importance in Lombardy. There are individuals whose sole but respectable incomes are derived from such operations. They are possessors of a given volume of water which they have purchased out of the great canals, or they have several small springs or brooks which they have bought or inherited, united in one small canal, and conducted to such distances as the fall will allow, where it is sold to the cultivators. The greater part of the proprietors are also the owners, or have shares in the canals, from which they procure their water; but many amongst them, and especially those who extend their irrigations, are insufficiently supplied from their own canals, and must consequently buy it from others.

The distribution of water is settled for a term, with strict covenants between the parties. Fixed days and hours are appointed for opening and shutting the sluices, and watchful guards are appointed; but, in spite of all precautions, the courts of law are supplied with most abundant processes from the several parties. The volume of water is reckoned by means of a local measure called the *oneia*, being about two English inches. An opening is made through the sluice, which is three of these oneias in breadth and four of them in depth, and the water is raised two oneias above the top of the orifice through which the passage is made, in order to give due force to the current. This opening is calculated to discharge about seven cubic feet of water in a minute. With this, in twenty-four hours, seven acres of sandy meadow, or six acres of ploughed land, is deemed to be sufficiently irrigated. For the winter meadows, which will be hereafter noticed, a large portion of water is requisite, and the measure here described is applied to not more than one and a third acre. A mechanical contrivance, invented by Ferrari, an officer of engineers, has of late years been chiefly applied to the measuring of water, which has been found to be accurate in its operation; but it is difficult to describe without the drawing, which is given by the inventor in his work, *Descrizioni del modo con cui sono formate le bocche che estraggono l'acque delli naviglj di Milano.*

The value of water depends upon a variety of circumstances, and the purchaser can afford to pay more for that which is applied to gardens and to meadows than for what s wanted on arable land. The water of the canals is of nore value than that which comes immediately from springs or from small brooks. That water which has passed over the land is worth more than that immediatey from the canals, as it is supposed to bring with it more nutritive particles. In the vicinity of Milan the water of he Vettabbia is more valued than any other, because it ontains particles of matter collected from the filth of the ity. In that neighbourhood, the common water obtained from the other canals is generally, where a constant stream s bought, paid for at the rate of from L.40 to L.50 the neia. If it be bought for the winter only, the payment is not more than the same number of shillings. Some instances are stated by a writer of accuracy and veracity, where an oneia of water has been sold for more than L.600. (Breislak, *Descrizione Geologica della Provincia di Milano.*)

Whatever may have been the original component parts of the soil of Lombardy, yet, from the great facilities for irrigation, those lands which are susceptible of that operation have become the most productive of any in the kingdom, or perhaps of any in Europe. There are, however, some exceptions; they are indeed but few, and chiefly confined to the vicinity of Mantua, where, even with great power of watering, the land, which is mere sand, does not produce copiously.

These watered lands may be divided into three classes: The first of them, "convertible meadows," or, in Italian, *Prati a Vicenda*, are the most abundant, and are constantly increasing. They are prepared to be laid down in grass by previous corn or green crops, and those are prepared which require good manuring, and also best tend to clean the land from weeds. The course adopted, therefore, is to grow maize and then wheat, or to sow hemp, succeeded by millet, and that followed by wheat; or, in the first year to sow hemp and then millet, in the second year maize, and in the third wheat. In each of these rotations a half fallow is introduced, and the ground three or four times ploughed, and such fallowing is either in the spring or the autumn, as may best suit the variations in the rotation. Red clover is generally sown in the wheat, which yields a good crop the first year after the wheat harvest, which usually takes place in June, and in the following spring; but after that it disappears, and gives place to most abundant crops of white clover, which seems to be the most natural, and almost the spontaneous, product of the soil, and the seed of which must be scattered on the land by the wind from the fields around it. It continues in grass for three, or in some cases four years, during which time it is mowed three, four, and even five times in the course of the summer. During the process of fallowing, great pains are taken to remove any such inequalities of the surface as would impede the equal distribution of the water over the whole of the field. The soil is removed, by a machine contrived for that purpose, from any part above the level of the field, and thrown into the hollows. The field is divided into narrow beds, between each of which is a water-furrow. In the process of watering, these become first filled, and then from them the water is let in till it rises sufficiently high to cover the whole surface of the land. The same furrows, in excessive rainy weather, serve to drain the land of its surplus moisture. The mode of ploughing naturally raises the middle of the bed somewhat higher than the sides of it, but the difference seldom exceeds four or five inches. The application of fields of this description may be generally stated to be as follows: Three sixths grass, one sixth wheat, one sixth maize, and the remainder flax, beet, rape, or other green crops. There are, as must be obvious to any one acquainted with agriculture, many variations; but, assuming the crops to be grown in that proportion, we cannot be far from accuracy. The portion of the grass-land on these meadows is very great; in many instances where there have been but three mowings and subsequent feedings, they have yielded six London loads of hay to the acre on the average of years, and in some of the best farms near Lodi a load more. There may be mentioned amongst the convertible meadows, those which are chiefly cultivated with rice, which are on the lowest level, and where the watering is the rule, and the letting them dry the exception. The water on them is stagnant during the greater part of the growth of the crops; but, to change the rotation, it is in some years cultivated along with other plants. Such lands may be generally stated to yield, one half of them rice, and the other half an equal portion of clover, wheat, and maize. The culture of rice will be further investigated.

The second of the classes of watered lands are those denominated "permanent summer meadows." These are day by day diminishing in extent, as the cultivators become convinced that it is more profitable to change the plants for a few years, than to leave them constantly in grass. The difference in produce between these and convertible meadows arises chiefly from the gradual disappearance of the clovers, and their place being occupied by a variety of the common grasses. They are fitted more for having their plants converted into hay than those of the convertible meadows, and less adapted for the growth of those kinds of grass which are, in conformity with the general practice of the country, most beneficial for stall-feeding. After the last mowing, they are depastured by the oxen. Most of these meadows have on their banks willows, which are from time to time cut a few inches from the ground, and sold to the basket-makers with great benefit.

The most important portion of the land in Lombardy is that part designated as "permanent winter meadows." In laying them down, great attention is paid to levelling the surface, so that no inequalities may prevent the regular distribution of the water in passing over them, and that in no part there may be hollow places in which it can become stagnant. They can only be created in situations where a flowing stream can in all seasons at pleasure be turned over them. They are usually laid down by sowing them with *lolium perenne* or rye-grass, with about one part of red clover; and the sweepings of the hay loft are abundantly scattered. As these meadows grow older, other grasses appear; and in the later mowing of each year, a large portion of white clover is always found. These meadows are well dunged every year, and the omission of it, even once, is considered by good cultivators as an unpardonable fault. Thus, if the other descriptions of land are not manured, it is because all of them are sacrificed to the winter meadows. Everywhere are to be seen on them heaps of manure, which are to be prepared during the summer, in order to be carried out and equally spread over the surface in the autumn. Those who intend to mow their meadows in the middle of December, carry the manure on them in the latter end of September, and then begin watering them; but those who design to mow them in January, carry on the manure at the end of October, or till the middle of November. If sufficient manure be not obtained from the farm, either ground rape-cake or ashes are used abundantly for the purpose, and thickly scattered over the soil.

The manure is separated as much as possible before the watering commences. At first the water is turned over the meadows in very small quantity, that it may produce the solution of the manure, and thus sink it down to the roots of the plants before the force of the stream can carry it away. Afterwards the water is let on in greater quantities, and especially when the temperature of the air is below the freezing point. At such times the greatest attention is given to create such a current of water as shall prevent it from freezing. If the cold is sufficiently strong to form a thin coat of ice, which rarely happens, the water is instantly withheld, and thus the soil remains free from frost, whilst a thin sheet of ice covers it; and if the cold, as usual, is but for a few days, an additional stream of warmer water melts the ice or carries it away, and the grass remains uninjured, and continues to grow. If, however, the frost should be so strong as to freeze the ground, the first mowing of the meadow would be lost; but such occurrences are so very rare, that they are looked at without any apprehension, nor are any precautions adopted by the cultivators.

As the chief profit as well as the receipt of ready money to the cultivator depends upon the cheese he makes, it becomes of great importance to him to have an abundant supply of green food to produce the milk; and this, which the farmer is afforded in the north of Europe by the use of turnips, mangel wurzel, or meal in tepid water, is supplied in Lombardy, during ten or eleven months, by his winter meadows. It is hence not a subject of surprise that every other portion of his land is sacrificed by the Lombard farmer to the necessity of raising the product of his winter permanent meadows to the highest possible state of productivenesss.

As the lands here spoken of are continually in a state of producing crops, they would in time become exhausted in spite of the irrigation, if they were suffered to remain without the application of abundant manure. Although some considerable quantity of extraneous manure is to be procured from the large cities, by those cultivators who carry on their operations near to them, or to the canals connected with them, yet the larger portion is provided for by the live stock which is maintained on the land. The chief labour of ploughing, except in a part of Pavia, is performed by oxen, and horses are used for the carts and waggons only. The cows are kept in the best possible condition, in order to enable them to yield milk in the greatest quantity, and of the richest quality. The number of black cattle is considerable, as will appear from the following official account of what existed in 1823, since which they have much increased.

Provinces.	Oxen.	Cows.	Bulls.	Young Cattle.	Total.	Sheep.
Milan	16,753	40,089	517	4,929	62,288	4,669

Cremona	15,880	8,979	171	12,884	37,914	2,169
Total	146,576	271,788	3,905	85,551	507,811	226,479

As the number of young cattle is scarcely in due proportion to the cows and oxen, it may not be amiss to mention in this place, that the Italians used at one period to prefer the young cattle from Switzerland, and drew from thence a considerable number annually; but of late years their own race has been greatly improved, chiefly by the exertions of one enlightened gentleman, Signor Dominico Berra, a follower of the system of our countryman Bakewell, and the annual import of cattle has been diminishing for the last twenty years. The numbers thus brought in of all kinds from 1815 to 1819, were more than 50,000 on the average of the five years. In the next five years, from 1819 to 1824, the average number was 38,800. No official accounts of the subsequent years could be obtained, but there is reason to believe that the diminution had been progressive, and that at this time the number scarcely amounts to 20,000 yearly. In the whole period, however, the stock on the land has gone on gradually increasing.

The whole of these animals are constantly fed in their stalls, or, if sent out to graze, it is but for a very short period. The use of roots, such as turnips, ruta baga, and mangel wurzel, is almost unnecessary, as the cattle can be supplied with sufficient green food from the meadows the whole of the year. The farms where the convertible husbandry is followed have abundance of litter from the straw of the wheat, but especially from the leaves of the Indian corn, which, though good food whilst they are green, are, when they become dry, used in the cattle-stalls for their bedding. Whilst this practice of stall-feeding has been found by long experience the most favourable to the health of the cattle, it is decidedly preferable on account of the vastly greater quantity of manure which it produces. On all the meadow farms a great number of pigs are fattened on whey mixed with the flour of Indian corn. These are put into the styes when they have attained the weight of 100 or 110 pounds, and are kept there during five or six months, till they attain the weight of 350 or 360 pounds. It is found that twenty such pigs yield ample manure for four or four and a half acres of the meadow-land. This kind of manure is highly esteemed for that purpose, but more especially so when proper reservoirs are constructed, out of the influence of the sun or the rain, for the preservation of the urine of the animals. In Lombardy are many small occupiers of land, who have not a number of cows sufficient to yield as much milk as will make a cheese daily. These sell their milk to the cheese-makers near them. In their agreement for the milk for the year, the purchaser contracts to keep in the seller's styes a number of fattening pigs, determined upon by a calculation of the quantity of milk which the cows will yield. It is commonly believed that the number of swine annually fattened by the meadow occupiers amounts to more than 140,000; and, from the great application of the flesh to hams, bacon, and especially to sausages, it does not appear to be an exaggerated estimate.

In a country where the land is chiefly ploughed with oxen, and where, as in Lombardy, much work is performed with the spade and the hoe, the number of other beasts for draft will be proportionally inconsiderable. This is the case here, as the following official account shows, as far as relates to the government of Milan.

Account of the number of Draft Cattle in 1823.

Provinces.	Horses.	Mules.	Asses.
Milan	11,556	1,974	2,789
Bergamo	6,349	2,881	3,033
Brescia	4,897	2,172	1,952
Pavia	5,048	351	249
Como	1,432	1,993	2,253
Mantua	4,025	1,118	2,213
Lodi	8,330	482	600
Sondrio	1,108	616	499
Cremona	1,993	825	456
Total	44,738	12,412	14,044

So scanty a stock of this description of animals can yield but little manure, how carefully soever it may be preserved; nor, with the addition made to it by the 226,479 sheep that are kept, will it bear any comparison with that arising from the half million of black cattle.

It deserves notice with reference to this subject, that the rural parts of Lombardy exhibit but few houses except those of the mere peasantry. The proprietors of even the smaller properties, though they may in some measure be viewed in the light of cultivators, yet, placing their estates in other hands, on the system of the *meta*, seldom find it necessary to reside on or near them, and are satisfied with visiting them at the seasons when the produce is to be divided. When the estates are of small or of moderate extent, or when they are large and comprehend several farms, the superintendence is intrusted to their agents. Such agents, also, in some cases, have the disposal of the share of produce, and account for the proceeds to the proprietors of the soil.

The great body of the population who are in circumstances of even moderate ease are thus collected in the cities and large towns; and in them is thus also collected that mass of corrupted vegetable and animal substances which is most adapted to the purposes of manure, and which is carefully preserved for that application. The cities and towns thus contain a larger proportion of the whole inhabitants than most of the other parts of Europe. If the numerical portion is not greater, the portion who by their mode of living produce the greatest quantities of exuviæ, which are convertible into manure, is much larger. Such of these substances as are of the liquid kind, or are the most easily reduced to that form by putrefaction, are carried into the canals and rivers on which the cities and towns are built; and, when their water is distributed over the first fields with a gentle motion, to enrich them by the deposition of the matter they contain in suspension, no other manure is required to be applied. Whilst the lower grounds near the cities are refreshed by these means, the higher grounds are supplied, with little expense of labour in the conveyance, from the substances which retain a solid or less soluble form.

The management of manure when collected is not so universally attended to as it ought to be; but the best cultivators have adopted a plan that is found highly beneficial, and is likely to be extended. Large sheds are built, sufficient to cover the dung-hills. A bedding of mould is formed about one foot in thickness, on which the dung is heaped to the height of five or six feet. The roof protects the heap from the great quantity of rain which falls in the winter months, and in an equal degree from the excessive drying influence of the sun during the burning months of summer. The fermentation process is regulated from time to time, as occasions require, by the application of the liquid matter from the cattle, which is collected in the cess-pools near the stables and cattle-stalls. Berra asserts that the most profitable money expended on a farm, is that which is applied to building sheds for the reception of dung heaps. Whenever there is an opportunity of doing so, the ashes collected from the bleachers of linen, and those from the soap-boilers, are abundantly used as manure, and are found peculiarly beneficial for the grass land. It is necessary however to use them in very dry weather, when they can be most equably scattered upon the surface. When the air is damp they run together into lumps, which it is difficult afterwards to break.

With the best farmers it is the custom every year to clean out the small canals of irrigation that are formed in every part of the meadow-lands. These ditches contain a compost of various earths, with a large quantity of vegetable and animal matter produced by the decomposition of many organic substances. It is obvious that each of these canals becomes a reservoir, in which is deposited the fat which the water has brought, and which being mixed with the earth in them, must have a great degree of activity in promoting vegetation by the portion of gas it generates, which forms the food of the several kinds of plants.

In some lands of an inferior quality, the practice of growing green crops, and ploughing them in to form manure, has been introduced. A kind of bean called fisole, a species of lupin, grows almost spontaneously on some of even the poor soils. When they are cultivated they produce a large quantity of succulent vegetable matter, which, when covered with earth, and mingled with it, forms an excellent pabulum for other plants. By two operations of this kind in succession, some of the poorest soils on the hills of moderate height have been sufficiently enriched to bear profitable crops of wheat. There is a part of Lombardy, not inconsiderable, where very little or no manure is applied to the land, and yet it is cultivated with corn, though the crops grown are very scanty. It is a portion of the delegation of Mantua, and not far from that city. It is easily susceptible of irrigation, but the soil is one of the poorest descriptions of sand. It is chiefly cultivated by small occupiers. These tenants have no cattle of any kind, and the whole labour is performed by the sole use of the spade and the hoe. Their dwellings and their clothing are of the most wretched description; their food of the coarsest kind, and of that they have at times a bare sufficiency. Their usual course of cropping is alternately with Indian corn and wheat. The farms are from four to eight acres in extent, and are divided into two equal parts, growing the two kinds of corn. One half of the produce is delivered to the proprietor, out of which he pays the taxes, and the other is for the subsistence of the occupier. In some cases the owner takes that half which consists of wheat, and the tenant is supported on the Indian corn. The value of these is nearly equal, as the price of wheat is commonly about one third higher than that of maize, whilst the quantity of the latter exceeds that of the former in about the same proportion. The maize is the sole food of the farmer, and is more convenient to him, as it can be converted into aliment without any other operation previous to its culinary application. It is by those who use it deemed the most healthy food for the working classes. Although the soil is poor, and little or no manure is applied, yet crops are raised, one half of which maintains the labourers who are occupied on the soil, though in the most wretched manner. As the maize is nearly three months in the earth, and the wheat scarcely more than six months, there is an interval between the crops, during which the soil, by being frequently turned over by the spade, imbibes a certain portion of oxygen, which, with the addition of water by the irrigation, furnishes food for the plants.

A district adjoining to this, with a soil somewhat less sterile, but capable of constant irrigation, is chiefly cultivated with rice, growing almost continually, or with very short intervals, in the water. The inhabitants are scarcely maintained on better or more abundant provisions; and, on account of the maladies produced by the stagnant water, are remarkable for their sickly appearance, and for the short duration of their lives.

Lombardy comprehends a large portion of the Alps within its limits. The elevated pasture-lands on these mountains are stocked with cattle only during the summer months. At that time the peasants take up their temporary residence in the chalets, and there convert the milk of the cattle into butter and cheese, as is practised in the adjoining Swiss cantons. The dung of the cattle serves to refresh the pastures during the summer, but no extraneous manure is ever applied to them.

Some mineral manures are used, the most important of which is gypsum, which is ground in mills, and then scattered on the clovers and the grass. Lime is used as a manure in some of the provinces. It is laid on the ground in heaps in October, and covered with the soil; and after the sowing of wheat, the compost with the lime, completely slaked, is spread over the field. The quantity of lime is very small.

In taking a view of the amount of the produce of land in Lombardy, it may be best to begin with the estimate of the marciti, or winter-watered meadows. These are commonly mowed four, five, and even six times in the year; but it is not very easy to determine the quantity of hay they yield, because the chief portion of their produce is consumed by the cattle in the stalls, in the form of grass. One of the most accurate of the practical cultivators (Berra, already mentioned) has constructed a weighing bridge at his farm, over which every load of grass brought from his meadows, as well as the manure carried on them, is weighed and registered. According to him, the average produce, for a series of years, has been as follows. They are kept by him in the weights and measures of the country, but are here reduced into English hundredweights, and English statute acres.

			lbs.
1st	mowing in	January	11,160
2d	ditto	March	16,512
3d	ditto	May	17,220
4th	ditto	July	9,664
5th	ditto	September	8,244
			62,800

That is, $560\frac{3}{4}$ cwts., or 30 loads.

The whole of the grass which is cut in January and in September is eaten in the green state, and the hay is made almost exclusively from what is cut in May and July. In what is converted into hay, it is found that there is a loss of weight by drying equal to three fourths. It is supposed that, from its containing so much more water, the grass cut in January and September would lose five sixths of its weight, and that cut in March four fifths. This view would give six loads of the finest hay as the annual produce of an English acre. There is good reason to believe that this may be near an accurate estimate, because the best meadows frequently, in the two mowings of May and July, yield more than at the rate of five loads per acre; but these are in the vicinity of the city of Milan, where the water that irrigates them is more fully impregnated with the rich drains from the city than that at a greater distance from it. From the last mowing in the beginning of September, till the end of November, the cows are fed on the meadows. Thus to the estimated crops of hay must be added the value of this pasture for the cattle during about two months. The usual price for the best hay in the cities is about 40s. sterling the load. The cost of making it, where the weather is so settled as it usually is in Lombardy, must be trifling, and that with the mowing and carrying cannot exceed the value of the after-feeding, so that each acre will give a profit of L.12 sterling annually. It is not then surprising that such land can be sold as high as 1000 lire the portica, or L.200 sterling the English acre, an occurrence by no means unusual.

The profit of these meadows does not arise from the sale of hay, which, in a country where few horses are kept for pleasure, must necessarily be very insignificant, but from the fattening of cattle in a small degree, and the operations of the dairy as the most important pursuit. The dairies are extensive, and carried on with the greatest care, and most scrupulous attention to cleanliness. The dairy-farms in the three provinces of Milan, Lodi, and Pavia, are mostly occupied by persons of competent capital; many by the proprietors, and the rest by tenants who are not metayers, but have leases for a term never exceeding nine years, at a fixed money rent. They, unlike the farmers in other parts, are the owners of the live stock, and of the implements of husbandry, and have comfortable dwellings, moderately furnished, and are well informed and active, and with diligence unite much economy.

The dairies of the three delegations of Milan, Lodi, and Pavia occupy the second place in the lists of articles as regards the amount, that become the exportable productions of the Milan division of Lombardy. The cheese distinguished by the name of Parmesan is to be found in most parts of Europe, and has long enjoyed a great reputation. It may perhaps have been originally, or at some early period, made in the duchy from which it derives its name. It is not now known in Italy by that name, but bears that of the delegation where the most of it is produced. It is commonly called *Fromaggio Lodisana.* At the present day little or none of it is made in Parma. The annual export of this cheese to foreign countries amounted to 1,800,000 pounds in the year 1824, and in each succeeding year has gone on increasing, besides what is consumed in the Italian and German provinces of the Austrian empire.

The operative part of making the cheese is confined to experienced practical men, who acquire a tact that enables them to time the several steps of the process with great accuracy, and, without the aid of a thermometer, to ascertain the requisite heat of the materials in each of these steps. From the nature of the climate, the milk will not keep long, but a cheese must be made every day. The cheeses are most valuable when they are large; and as the greater number of farmers have not milk sufficient to make such a cheese daily, the milk is sent by them to other farmers, so as to make up the requisite quantity. Thus, on one farm near Lodi (Tavazzano), where only twenty-seven cows are kept, the milk is sent very early to a neighbouring farm, where sixty-three cows are kept. Sometimes four, or five, or more, small farms contribute their day's milk to one who has more stock, to make the cheese; and there are instances where the cazarro or cheese-maker buys the whole of the milk from which his cheese is made.

The cows are milked evenings and mornings, in the first case about five or six o'clock, in the second at daybreak, or just before. The milk of the evening is skimmed of what cream has risen on it before eight o'clock, and the milk of the morning, of that small quantity which is thrown up between day-break and that hour, and from that cream butter is made. Though the Parmesan cheese is thus made from skimmed milk, yet a very large portion of the cream is still left in it to enrich the cheese. The milk is then placed in a kettle, and warmed to the heat of 22° Fahrenheit, when the rennet is applied, the effect of which is increased by a small addition of vinegar, and sometimes of grated cheese, and a very small quantity of pepper. The other parts of the process so much resemble the practices in the best dairy-farms in England, as not to require any special notice.

It is salted after it is made, by sprinkling the surface with that substance daily during six weeks, and turning the cheese to imbibe the particles. These cheeses vary in weight when fit for sale, from fifty-two to 122 pounds avoirdupois. They are kept some time before they are sold, a few at eight months, some at one or two years old, a less number at three, and a few at four years old. It requires much care to preserve the cheese against the heat of the climate. At Codogno and Corsica, where the wholesale trade is carried on, there are large magazines on the ground-floor, twenty feet in height, with shelves around, on which each cheese is placed singly. They have large windows, which are carefully shut to exclude the sun the whole day, but are opened during the night. It is difficult to estimate correctly the average quantity of butter and cheese produced from a given number of cows. In one farm (Meleg-nanello) in the province of Lodi, there were on the farm ninety-one cows, from which were made 173 cheeses, varying in weight from fifty to 120 pounds, but the weight of which the man who made them averaged at 100 pounds each. These had been made in the preceding six months and a half. Supposing the remainder of the year to be equally productive, the whole herd would have yielded on an average at the rate of 370 pounds in the year. There was, however, no certain accounts of the quantity of butter made on the farm during the period; and the quantity of cheese alone, though correct, does not give any certain data upon which to frame an estimate of the productiveness of the animals. The proportion which the cheese bears to the butter varies in the different irrigated provinces. Thus, according to the estimate of the accurate Signor Berra,

lbs. lbs.
100 pounds of milk yields in Lodi $2\frac{38}{100}$ of butter, $6\frac{37}{100}$ of cheese.
100 pounds of milk yields in Milan $2\frac{16}{100}$ of butter, $6\frac{13}{100}$ of cheese.
100 pounds of milk yields in Pavia $1\frac{94}{100}$ of butter, $5\frac{88}{100}$ of cheese.

A writer in a periodical work, *Annali di Agricoltura*, gives the medium product of each cow to be 416 pounds of cheese and 178 pounds of butter yearly. Another person, a practical and accurate man, who had passed much time in examining every portion of the agriculture of the Austrian Italian dominions, gave, as the result of his investigation, a calculation framed from data collected from a considerable number of farms of various extent. According to him, the annual produce from each cow is from 102 to 120 pounds of butter, and from 340 to 392 pounds of cheese. As the informant was perfectly master of the local weights and measures, which vary in each of the provinces of Austrian Italy, some credit may be given to the estimate; and the more so, because it makes the produce of the dairies the lowest, though it far exceeds any returns of the produce of those of Holland, England, or Germany.

The farms in these provinces are generally small. One of 250 English acres would be denominated large; and though there are a few that exceed that extent, yet the greater portion of the irrigable land is occupied by farms much below one half of that extent. Amongst the occupations that are confined exclusively to the *marciti* or winter-watered meadows, many, perhaps the greater part, do not exceed forty acres. As the farms are small, so there are very few proprietors. The family of Luoghi Pii have the greatest tract of the best land in the province of Milan, divided into many farms, and said to amount to 3000 acres. No other exceeds one third of that extent.

The value and the rent of land depend less upon the natural fertility than upon the local situation, on the power of irrigation it can command, and on the capital expended on making roads to it, fences around it, and in erecting houses and agricultural buildings. In the vicinity of the city of Milan, those winter-watered meadows have the greatest value which are to the south, and are watered from the canal of Vettabbia, whose water is furnished by the Riviere Seveso and canal of Martisana, which flow through the city, and bring with them the precious manure of that populous place. The present price of such land is about L.130 sterling the English acre; and, if it has good roads and buildings, may be let to good tenants at from L.6 to L.7 per acre. The land which has not sufficient irrigating power to form winter meadows, but enough for the purposes of convertible husbandry, is worth from L.50 to L.60 per English acre, and may be let at from 60s. to 70s. per acre. In these cases the taxes and repairs are paid by the proprietor, as well as the contributions collected for keeping in proper repair the canal by which water is conveyed. Some parts of the irrigable provinces have lands of inferior natural quality, but being on the banks of the Po, are well calculated to grow rice, by their capability of being constantly flooded. An estate of that description in the province of Pavia, with four acres of winter meadow-land, five acres of land in convertible husbandry, with sufficient for the purpose of occasional irrigation, fifty acres of rice land, and a house, garden, and homestead of two acres, was lately sold at L.2000 sterling, or nearly L.33 per acre. It was doubtful if the purchaser would occupy it or let it, but it was thought a rent might be obtained of somewhat more than L.100 per annum, the owner, as in other cases, paying the government territorial tax.

The value of land is much affected by the rate of the territorial taxation. This is founded on a very old valuation, and the parts that were then in a very high state of cultivation and irrigation must contribute in proportion to that state, whilst the properties that have since been reclaimed, either by irrigation, manuring, or by planting mulberry-trees, or vines, or other valuable trees, pay a less rate, and are consequently of greater value. In the provinces of Milan, Lodi, and Pavia, where the great steps in irrigation were made before the valuation which is now acted upon was framed, the territorial and commune imposts amount to nearly twelve shillings per annum for an English acre, on an average of the whole land, and consequently they are much higher on that of the greatest value. This circumstance alone makes it difficult for a stranger to generalize with any accuracy the value of land, or the rent of it in due proportion to the amount of the sum invested on it. An opinion generally prevails, that the capital laid out in land might be assumed to pay an annual rate of interest of about four per cent., but that as most of the rent, with the exception of the irrigated provinces, was paid in produce, those who employed factors to manage their property, or who managed it themselves, without great judgment and perpetual watchfulness could scarcely calculate on obtaining more than, if so much as, three per cent.

It may serve to give some idea of the difficulty of ascertaining the amount of the rent of land, if a slight view be taken of the description of the classes of persons occupied in cultivation. The first of these somewhat resembles the middle-man now generally to be found in Ireland. They rent large portions of land at a money price, and either let it out again to sub-tenants, who work it, if in small lots, by means of their own family, with an additional servant or two, or, if large, by day-labourers and their families, who are established on the property.

The next class is called *Affitjuoli*, or farmers. These are the most advantageous to the proprietors, and they are tolerably numerous, as well in the Venetian as in the Lombard provinces. In this class is comprehended the farmers in the watered provinces, whose chief object is the making of cheese, in some cases combined with the culture of rice. These lay out large sums at first, and have a good stock of cattle and utensils, and a sufficiency of capital. The advantage of this class to the proprietor is obvious. They take from him the labour of superintendence, and all risks from failing years and from loss of cattle; and, having leases renewed every nine years, they can have no inducement to destroy the fertility of the soil. Though many of them have more extent of land, the greater proportion may be described as occupying from seven to twenty-five acres.

The third, and by far the largest class of all, are the *Coloni*, colonists, sometimes called *Pigionanti Chiusuranti*, who occupy from three quarters of an acre to an acre and a half of land, with a cottage, or more correctly a hovel. These premises they take either of the proprietors, of the middle-man, or of the farmers, and pay a rent by a share of the produce. They are in fact day-labourers, and, besides what they pay in produce, must work for their superior at a lower than the customary rate of wages. Some of these, however, have a little larger extent of land, but rarely so much as two acres. Such a one pays to his superior a fixed quantity of corn yearly, or commutes that for money, and an agreed proportion of the other products, such as wine, or in many cases the whole of it is divided. When these shares are not too small, and the ground is fruitful, the most common custom is to pay a distinct measure of corn, and the half of the wine. The meadow-land is paid for in money, in silk-worms' eggs, or in cocoons. The cattle, perhaps a cow and a donkey, are furnished to the colonist on credit, and if his terms are favourable, and he gets forward, he becomes the proprietor of them, as well as of the utensils; but if the land is unproductive, or the shares of the proprietor too great, he must give up the cattle and the utensils, and may then be permitted to continue on the land, giving to the proprietor at least one half the produce, or, if the crops prove heavy, a still larger share.

The farmers of the great estates in the watered provinces are in prosperous circumstances, and generally well educated persons; and their chief occupation consists in overlooking the workmen, and making the due bargains for the disposal of their produce. They are also necessarily furnished with some capital, as a proof of which, one near Lodi, occupying a farm of 250 English acres, upon which were fifty-eight cows, a bull, and eight horses, and who had on hand the cheese made in the six preceding months, asserted that the value of his stock exceeded eight hundred pounds sterling. On that farm there are twenty-two families of day-labourers. Six or seven men, the heads of those families, are in the constant employment of the occupier, either as herdsmen, ostlers, or stable-servants. All the rest and the females and children are only employed when there is work to be done, for which they are paid daily wages, viz. to the men about fourpence halfpenny a day, to the women threepence, and to the children from twopence to threepence, according to the age or strength. They have also one meal a day, consisting of rice and beans, but no wine, and only milk one day in the year. Some of them are occupied, on fixed terms, in rearing articles that require a great portion of labour to prepare them, and receive a proportion of the product. Thus, of flax they receive one half, of maize one third or one fourth, and of rice one seventh. Their condition is generally very wretched, though when not wanted they may get occasional wages on neighbouring farms. They are, however, frequently in want of the common necessaries of life, are miserably clothed and housed, in case of sickness can obtain no medical relief, and are utterly destitute of instruction. In spite of the checks, the population is as rapidly increasing as in those parts of Europe where the labourers are placed in more favourable circumstances. The only alleviation to their accustomed wretchedness is but a temporary one during the time the silk-worms are at work, or have finished their spinning, and the silk is to be wound from the cocoons. In most of their habitations they hatch a few eggs if they can find money or credit to buy mulberry leaves; and if not, they have some occupation in winding the silk for those who are a little better situated.

In those provinces of Lombardy which are not to any extent capable of irrigation, there are few large farms, and no substantial or intelligent farmers. The greater portion of the land is divided into small allotments of a few acres, either directly by the proprietors, or through the management of middle-men. The real cultivators, called also colonists (*coloni*), with their wives and children, perform all the labour, and contract to deliver half of the raw produce to the proprietor. Their condition must be worse than that of day-labourers in other countries. It is obvious to any person who has attended to the subject of husbandry in any part of Europe, that the cost of labour in cultivating corn must amount to more than half the value of the produce where the labour is in part performed by horses or oxen; but in this case all is done by human hands, and it must be of more real cost, and consequently the landlord draws more from the land than his due proportion, and that is at the cost of the sweat of the brow of his tenant. On land in England of such a quality as to bear three quarters of wheat per acre, and which could be sold at 56s. per quarter, no farmer would contract to pay one half or one quarter of that quantity as rent, even if the landlord paid the taxes; and the corn-land in Lombardy requires quite as much labour as it does in England. The rapid increase of population, and the difficulty of day-labourers finding employment, are such, that no proprietor finds himself at a loss to get occupiers on the metayer principle. It may perhaps arise from the nature of these contracts, that the owners of land are rarely the cultivators. The few who have attempted to cultivate have soon discovered, that though by hiring day-labourers, and farming in a better style, they obtain more raw produce, they draw from their estates much less net proceeds than they can now extract from them by means of the slovenly cultivation of their ignorant and suffering colonists. This description of tenants are as much bound to continue in their state of poverty and dependence as the slaves on the estates in Russia, or those who were till recently feudatories under the nobles of Germany. If the trifling property they possess is merely equal to the debt they owe their landlord, it is impossible for them to remove; and if they could remove in a state of destitution, it would be difficult to procure land elsewhere. The moral degradation produced by this system is not one of the least evils it generates. A constant struggle is going on to defraud the proprietor of that part of the share which is conditioned to be delivered to him, and the tenant feels no remorse at the fraud, but justifies it to himself by the hard terms upon which the land is let to him. All friendly intercourse is destroyed, the proprietor looks on the colonist as a thief, and the latter views the former as an oppressor. The depravity thus begotten tends to fill the country with numerous offenders against the laws, chiefly amongst the ruined colonists, who have nothing left when expelled from their narrow pieces of land but to take refuge in open or secret robbery.

The picture here exhibited, though a representation of the far greater portion of the peasantry of Lombardy, has some, but not numerous exceptions. Instead of one or two acres of land, a few tenants have from fifteen to twenty acres, and are enabled to keep two or three cows, which are stall-fed, and perhaps a horse or a mule. The cattle and utensils are their own property. They pay a moderate money-rent for the corn-land, and divide with the landlord in equal portions the wine, and the cocoons of the silk-worms. Such persons, if they perform the work by the members of their own families, subsist chiefly on maize, use none of the wine, and otherwise practise the most rigid economy, though they do not become rich, may live in a respectable and comfortable manner when compared with that in which the great body of the same class exist.

On the whole, the condition of the great mass of the colonists is very far inferior to that of the lowest class of agricultural labourers in England, France, or Germany, and nearly resembles that of the most wretched of the cottiers of Ireland.

The chief product which is furnished by Lombardy to external commerce is silk, which interests more or less every family in the country, and receives the greatest share of general attention. As the quantity and the quality of the silk depend on the worms that spin it, the subsistence of those worms becomes an object which engrosses much consideration. The leaves of the mulberry-tree are exclusively the food of the worms, and the greater weight of these leaves that can be gathered, the greater is the silk that is produced. In many parts are numerous nurseries, where those leaves are raised, with most careful cultivation, from seed. The beds in which the seed is sown are well and deeply ploughed or dug the year before, and manured with the most powerful substances. It is at last dug once more, made as fine and as level as possible, and the seed is then sown in rows about eight or ten inches from each other. It is slightly covered with earth, and also with hay and straw, the latter to protect it equally from the slight frosts which occasionally appear in winter, or from the excessive droughts which frequently occur in summer. In very dry weather they are watered as becomes necessary. As the plants grow, they are carefully weeded with the hoe, and are also thinned out. They grow but little in the first year, but considerably in the second, at the end of which, or at the beginning of the third year, they are transplanted from the seed-bed to the nursery-garden, and cut close to the eye. In the next year they are again cut close, and the stump grafted. In the fourth year, when the new shoots have formed what is to be the crown of the tree, they are cut into a hollow so as to resemble a basin, which is found the best shape, both for the fruit and the leaves. In the fifth year they are generally sold; or, when the nursery is kept by one who means to plant them on his own property, they are transplanted to the hedgerows or other spots where they are intended permanently to remain. The growth of the plant up to this period depends mainly on the manure which is applied to the nursery, but generally they have attained a diameter of from four to five inches.

The wild mulberry, or *Morus Alba*, yields the best leaves for the nourishment of the worms, and the silk they spin whilst feeding upon them is of the finest quality; but the quantity of leaves they yield is so small, that it requires a great outlay and a great number of trees to give sustenance to an extensive silk establishment; on which account they are grafted with other kinds of mulberry-trees, which have larger and dark-green leaves, and in such abundance that they yield at least double the weight of leaves. Attempts are now making, and experiments in progress, for obtaining a new genus of the mulberry-trees, which may unite abundance of leaves with greater fineness in the silk. According to Moretti, professor of botany at Milan, the finest silk is obtained from the wild ungrafted mulberry-tree, the next finest from one of a new genus produced by his experiments, the third from the grafted white mulberry, and the coarsest from the black mulberry. The fruit of none of these trees is in any estimation. In order to procure more leaves, the cultivators of the trees, every fourth year after the leaves have been stripped, cut off all the smaller branches quite close to the principal ones. In the succeeding year the leaves are not taken from the new shoots, but they are in the next and following years; and in the fourth year, when the shoots have attained a diameter of four inches, they are as bushy and thick as if they had not been tapped.

It is difficult to form an average of the produce of mulberry leaves from each tree, as much depends on the soil, but more upon the age of the tree. As soon as they have attained six inches in diameter, they yield from 19 to 27 lbs., and continually increase their produce till they attain a diameter of two feet, when they yield from 220 to 260 lbs. Having then attained their full growth, they continue to increase in produce till they yield in some cases, but extreme ones, as much as 500 lbs. The market prices of the leaves undergo a great fluctuation, varying sometimes one hundred per cent in a fortnight. In June of the year 1833 they were sold at 3s. the hundredweight, and two weeks before at 7s.

Some persons who have none, and others who have but few mulberry-trees, yet breed silk-worms. They are careful to make contracts for what they expect to want, in March or April, when they are cheapest. It not unfrequently happens that by a storm of hail, which is not an unusual occurrence, the price is so raised that the breeder, instead of drawing a profit from his operations, finds he has paid more for the leaves than he can obtain for the cocoons. There are persons so skilful in estimating in the spring the weight of leaves which each tree will produce, that their assistance is commonly resorted to by those who make bargains for the leaves. When the first signs of life begin in the worms they eat very little, but when they begin to spin they require a considerable quantity of food. The price of leaves naturally rises very high; and if at that time a hail-storm should occur, the advance becomes most ruinous to those who are compelled to purchase. In general the mulberry-trees are, by the terms of the leases, let to the farmers or colonists, who divide the cocoons equally with the proprietors of the land. The tenant provides half the eggs, and superintends the insects, feeding them, and keeping them clean whilst they are working; the other half of the eggs, as well as the leaves, are the contributions of the landlord to this equally joint-stock concern. The tenant estimates what worms can be nourished by the quantity of leaves the trees upon his farm will feed, and the two parties procure the estimated weight of eggs. If the tenant miscalculates, or if a hail-storm destroys his calculation, he is bound to purchase such a portion of leaves as will subsist the insects through their working period.

The planting of mulberry-trees, and the consequent produce of silk, have been favoured by circumstances which have naturally led to a rapid extension of every branch of that trade. It is an object of attraction to every grade of society, from the greatest landholder to the lowest of the colonists and day-labourers; and these have all been stimulated by the constantly advancing price of the raw silk in each year from the return of tranquillity in the year 1814 to the present time; but the most striking advances of price were those which took place from 1820 to 1822. From the vast number of trees, only an approximation to the rate of increase can be made. It has, however, been ascertained of late, that three fourths of all the mulberry-trees of Lombardy are of less than thirty years growth, and that one half of that three fourths, consequently thirty-seven per cent. of the whole, are under fifteen years of age. The greater portion of the mulberry-trees in Lombardy are to be found in the dry provinces, though some few are planted in the irrigated districts. From the city of Milan to Varese, from that city to Como, between Lecco and Bergamo, quite to the river Adda, the cultivation of vines has almost everywhere given place to that of mulberry-trees. One of the finest views in Italy is from the high ground about Bergamo, which comprehends the hills of Brescia and Bergamo, and the extended plain of Lombardy. Around the city the appearance is that of an extensive orchard or fruit-garden; but the trees are planted chiefly for the leaves, and are found, with less annual expense, more profitable than any trees cultivated for their fruit. The lowest calculation of the average profit of the trees makes it, including all ages, from five to fifty years old, nearly six shillings sterling from each tree annually.

In the lower parts of Lombardy, in the irrigated provinces of Milan, Pavia, and Lodi, the cultivation of mulberry-trees, and the consequent breeding of silk-worms, are by no means extensive; yet, even in each of these of late an increase has taken place, and preparations are made, by which it is calculated that in three years the number of the trees will become double what they are at present. The greater number of mulberry-trees are at this time to be seen on the sterile and strong soil in the province of Verona, especially between that capital and Desenzano, and from Castelnuovo, through Vallego, quite to Roverbello. The surface of these districts consists of masses of pebbles, rounded by having been washed down at some remote period from the neighbouring Alps, and in which the culture of corn will scarcely repay the cost of the labour devoted to it. As much land is mingled with these stones, which is favourable to the mulberry-trees, vast numbers have been everywhere planted. A prejudice is said to prevail in these districts against the practice of engrafting, and that owing to it the quantity of leaves does not bear the same proportion to the number of the trees, as in the other parts of Lombardy.

The eggs of the silk-worms are not preserved by all those who manage their working, but are made an object of trade by a few persons whose establishments are upon so large a scale as to make it worthy their attention, and who, when preserving for themselves, collect greater quantities for sale. They are sold by weight, generally at about two shillings the English ounce; and some individuals have collected in one year as much as 2500 ounces, though one tenth of that weight is nearer the average of the whole of the several producers. The eggs are divided into three classes. The worm from the first of them casts its skin four times, and is of a large size, and an ounce contains 24,024 eggs. Supposing each egg to produce a caterpillar, and each caterpillar a cocoon, as 110 cocoons weigh a pound, the whole ounce of eggs will yield 218 pounds of cocoons. The second also casts its skin, but the animal is of a smaller size, as are the cocoons; an ounce of them contains 25,185 eggs, and the cocoons produced from them weigh less, 216 being a pound, and consequently the whole weight of the cocoons is only ninety-six pounds. The third class casts its skin but three times, an ounce contains 31,004 eggs, 440 cocoons weigh about a pound, and the whole weight of the cocoons is only about seventy pounds.

In every house, room is made for laying out the worms as soon as any symptoms of life appear, and in even the poorest cottages of the colonists, who have but a single apartment, it is so contrived that some space is allotted to them, and the inhabitants shift as well as they can during three weeks or a month. Tables of reed are formed, about two feet and a half in breadth, and from fifteen to eighteen feet in length. These are suspended from the roof, the upper shelf two feet below it, and others at a foot distance, with the lowest of them two feet from the floor. The windows are made of paper, to prevent currents of cold air, and too great heat; the shutters are of straw, and the door consists of a piece of old linen cloth. Within, the place is kept in darkness, except when the worms are to be fed or the place cleaned out, when lamps are used. In many of these places, thermometers, made for the express purpose, are kept to ascertain the temperature. They are made of spirits of wine, and show no other change of heat than that between the 16th and 20th degrees of Reaumur, to which limits it is deemed necessary to confine their range of temperature. In the houses where there are none of these simple instruments, habit has given a tact, by which the people ascertain the degree of heat with tolerable accuracy.

Some of the colonists within a season produce as much as 140 pounds of cocoons. Taking their half of them at seventy pounds, and estimating them at the average price (for there is great variation in the price), viz. two shillings and threepence per pound, it will yield for a month's labour near eight pounds, which is an enormous sum for persons in that condition of life in that country. From it, however, must often be deducted the cost of leaves, when the landlord's trees do not yield as much sustenance for the insects as the tenant has calculated when purchasing the eggs.

The rapid growth of these insects is one of those singularities in natural history which seemed to be worth collecting and recording, as is also the increased space they occupy, and the increased portion of food they devour, in the several periods of their short existence. From their escape from the shell to their death is commonly thirty-two days, which is usually divided into five periods, according to the change observable in them, thus:

1st period	5 days.
2d do	4 do.
3d do	6 do.
4th do	7 do.
5th do	10 do.
	32

The space required for an ounce of the eggs is, in the first period, $2\frac{28}{100}$ square feet; in the second, $4\frac{56}{100}$; in the third, $10\frac{83}{100}$; in the fourth, $25\frac{65}{100}$; and in the fifth, 57 square feet. According to a course of experiments made by Count Dandolo, it appears that the weight of 100 silkworms at the different periods is as follows, viz.

100 at their first appearance	648	grains.
100 at the 1st period	9,726	do.
100 at the 2d ditto	60,912	do.
100 at the 3d ditto	259,200	do.
100 at the 4th ditto	1,051,700	do.
100 at the 5th, when they have attained their greatest weight and size	6,156,000	do.

Thus, in the thirty-two days they have increased nearly 9500 fold. The same course of experiments shows the weight of mulberry leaves which is given to the worms produced from one ounce of eggs to be as follows:—

n the 1st period	$3\frac{5}{10}$	pounds.
n the 2d ditto	$10\frac{5}{10}$	do.
n the 3d ditto	35	do.
n the 4th ditto	105	do.
n the 5th ditto	640	do.
Total	794	do.

As the leaves are kept at least one day, and sometimes nore, after they are gathered, they have lost by drying sixty-one pounds, and by cleaning from dirt and small sticks eighty-three pounds, so that to supply this food 939 pounds of leaves must have been procured. It is found in cleaning the insects, that the remains of the leaves which are not consumed, consisting of thick stalks in the middle of each leaf, and some of the relics, weigh 329 pounds. Thus the actual food is 465 pounds. According to those experiments, as seventy pounds of cocoons were procured from the ounce of eggs, each pound must have required $11\frac{35}{100}$ pounds of leaves as they come from the trees, or $6\frac{64}{100}$ of real vegetable nourishment. The obtaining the cocoons is a step of great importance in the whole operation of procuring the silk. With the small producers, and it is they who, after all, furnish the far greater quantity, their labours are for the most part at an end, as they generally sell them to other persons, who make the winding the silk, and the subsequent operations to fit it for the manufacturer, a distinct trade. There are, however, some few large establishments, in which the silk-worms are nursed, and in which the cocoons are wound off, and all the steps taken to prepare the silk for market. It would lead to some very long description and discussion, to show satisfactorily and accurately the relation which exists between the quantity of leaves and the weight and number of cocoons, and also the relation between the number and weight of cocoons, and the actual weight of silk prepared for the manufacturer. It has been minutely discussed by Dandolo, with whose results this part of the subject may now be closed. One hundred pounds weight of cocoons yield about eight pounds and one third of silk. The thread drawn from each cocoon must be about 800 feet long to weigh a grain. Each of such cocoons yields nearly one grain and a half of silk. One pound of them will produce in length 17,600 feet. It requires about one hundred and fifty pounds of mulberry leaves to produce one pound of silk.

It is difficult to ascertain the quantity or the value of the silk annually produced at present from the soil of that part of Lombardy contained in what is now within the boundaries of the government of Milan. Much of it is consumed within that government. A much larger portion is sent, without any official notice, to be manufactured in Austria Proper, in Bohemia, and in Hungary. The greater part of what goes to the Prussian factories on the Lower Rhine, as well as that for France and for the English market, passes by land-carriage; and the accounts, not being kept for purposes of revenue, are not collected with exactness, nor brought into a focus. The only account whose authenticity can be relied on, is an official paper transmitted to Vienna for the year 1824, since which period the growth of silk has been constantly and extensively increasing.

Worms.	Imports.	Exports.	Value of Imports.	Value of Exports.
Cocoons	128 quintals.	1,179 quintals.	83,738	827,507
Raw silk	30,548 pounds.	312,899 pounds.	1,619,054	17,522,377
Spun silk	93 do.	634,593 do.	5,998	41,883,144
Other kinds	590 do.	9,113 do.	7,269	764,380
Manufactured silk goods	...	...	...	3,291,896
			1,716,059	64,289,304
				1,716,059
				62,573,245

This account is made out in Austrian lire, of which hirty are about equal to a pound sterling, and thus give ne excess of the value of silk exported above that imorted as L.2,085,774 sterling. Considering the increase of mulberry-trees within the last ten years, and the advanced price of silk, it will not be too much to assume the balance of exports in 1833 at L.3,000,000. After reviewing the productions of most value, the cheese and the silk, Lombardy. a slight notice may be taken of the results of those other operations of agriculture, which are almost exclusively confined to domestic consumption.

Amongst corn, that most extensively grown is maize. It is the chief nourishment of the working classes, and is deemed by them the most healthy and most strengthening of all grain. It has, too, the advantage of being most easily converted into wholesome food, requiring, unlike wheat, no assistance from the baker. It requires only a kettle and a little fuel to make it into polenta, a kind of thick pudding or gruel, which, without any addition, forms the common food of the peasantry. It is also a valuable product on other accounts. The grains in a green state are a substitute for green peas; the leaves, when fresh, are a fodder, on which cattle eagerly feed, and, when dry, they are used to make excellent beds, or rather mattresses; the stalks are used for fuel in that country, where fuel is scarce; and, finally, the feathery tops are converted into brushes for sweeping the houses.

This article is also cheaper than wheat, being commonly sold at about two thirds the price of that grain; but, from its being the food of the far greater part of the population, in seasons of great scarcity, such as those following the harvest of 1816 and 1828, the indispensable demand for it caused the price to rise higher than that of wheat. From the circumstances here stated, more than one third of all the arable land of Lombardy is destined to the cultivation of this grain, and the average product per acre is greater than that of wheat. It is grown almost indiscriminately on all kinds of soil; and the nature of the climate is but little regarded, as it is to be seen equally on the cold hills, and in the warm valleys of the provinces. The culture of it does not appear to have received any improvement since its first introduction. It is in some cases sown broadcast, and covered in with the plough. From this mode of sowing it, it can only be cleared of weeds by hand, and the earth is thrown round the plants in the same way; whereas, in the countries where it is sown in rows or drills, these operations can be more advantageously performed by appropriate instruments. The expense of this hand-hoeing and shovelling up the earth is said to be equal to the value of one third of the gross product of the crop. It is customary, after the bloom is off, to strip the plant of its leaves, and also to cut the stalks above the cobs or ears, which, if not done too early, is not injurious to the grain. There are several species of this plant. The most common is that with a large yellow grain, whose cobs grow about half way up the stalk, and which ripens in three months, if sown in the month of May. If it cannot be sown so early, or if it is sown after a crop of flax, or on clover after the first mowing, it is usual to sow another kind called brigantino, whose grains are smaller, and of a darkish brown colour. In the vicinity of Bergamo, the greatest quantity of maize is of this kind. There are some species of this corn of much smaller grains, called cinquanto and quaranto, from the number of days which pass between the sowing and the harvesting. These kinds are commonly sown on the wheat stubbles, or after a crop of flax or of rape-seed has been gathered. It is seldom very productive, and, if the field on which it is sown be poor, scarcely repays more than the seed and the labour.

In a country where the soil and the climate are so various as in Lombardy, and where the difference in the quantity of manure applied to the soil is so great in the several portions, it is impossible to arrive at any average calculation of the produce of grain per acre. Nothing more can be done here than to state a few facts on the subject. One very accurate cultivator on the richest irrigable land, to which abundant manure is applied, stated that his crops yielded annually in a series of years from fifty-nine to seventy-eight English bushels an acre. Another also, in the same circumstances, a few miles distant, gave his range of bushels at from fifty to seventy-eight per acre. The other side of the picture is vastly different. According to an official valuation in the revenue office at Milan, the following average of the produce of maize in some of the poorest provinces is given, viz. in Verona, the greatest produce is rated at fifteen bushels the acre; in Vicenza, from thirty-two to forty-two; in Padua, from twelve to twenty-one; and in Udine, from thirteen to twenty-two. No other provinces are noticed in the account. To this account of the average produce of maize may be added calculations made by two of the most accurate agriculturists of Lombardy. Count Dandolo informs us, that the average produce from the colonists on his estates near to Vanese, on whose fields the peasantry had been induced to plant the beans called fisole amongst the maize, was $21\frac{3}{4}$ bushels of maize, and $4\frac{1}{2}$ bushels of beans. The average on the whole of his estate, including the part cultivated by himself, is stated to be $32\frac{1}{2}$ bushels of maize, and $7\frac{1}{2}$ bushels of beans. Another intelligent agriculturist asserted, that, according to the best calculation he could make, and he had taken much pains on the subject, the average produce of maize did not exceed twenty-one metzen the jock, or twenty-five bushels the acre, which he considered to be a produce one third greater than that of wheat.

Rice is a plant introduced from India and China at some distant but not very remote period. According to some, it was known as early as the tenth century; but no one large field was cultivated with it, until a patrician of Milan, in the year 1522, first destined to it some marshy land upon his own estate in the province of Verona. In the provinces of Verona, Mantua, and Pavia, it is the most profitable grain that is grown; and in the provinces of Lodi and Milan it always secures to the farmer moderate benefit. Much of it is consumed at home, as those who do not subsist on maize alone have one meal a day of this article. Some of it is exported, but the amount of that portion does not exceed in value L.12,000 sterling. Rice is a marsh plant, and can only be grown where the land can be covered with water till it warms, and is very slowly dried up. The evaporation is injurious to human health, and hence laws are enacted regulating the distance which must intervene between the rice-fields and the cities and towns. Without these restrictions, rice would be more extensively cultivated. At present about 125,000 English acres form the extent of this culture. Some portion of rice is grown in the rich provinces, as one of the crops in rotation of convertible husbandry. In this practice, called *risare a vicenda*, it is most commonly sown after clover. The land is ploughed very deep, but not harrowed. The water is then turned on, so as to cover the surface, and to show any inequalities which remained by the use of the spade. The seed is then sown, or rather scattered on the water, having been previously steeped during eight or ten hours, to give it additional specific gravity, so that it may sink immediately to the bottom. If it were sowed after clover, two bushels of seed would be sufficient for one acre. When it is sowed, as is oftentimes the case, after maize, the quantity is usually three bushels.

The time of sowing is from the beginning of April till the middle of May. It remains covered with water to the height of from two to three inches, and in that state remains till weeding becomes necessary. That early sown requires the operation to be performed in the middle of May, that later sown, some time in June. It is executed chiefly by the females, who, with their lower garments tucked up, stand in water over the ancles, and with the hand pluck up the weeds by the roots. If the land were dry, the weeds would break off, and leave the roots to shoot out again. The most prevalent weed is the cockfoot grass, which, at an early period, it is difficult to distinguish from the rice. Besides this, there are several other weeds, chiefly of the rush kind. In the first year the operation of weeding is performed twice. If the same field be sown with the rice in the next year, once is deemed sufficient. This is the most expensive part of the process, and is said in the first year to require twenty-five days' work for an acre, which, as the employment is unpleasant and unhealthy, is commonly paid for at the rate of about tenpence per day. Much of this work is executed by the colonists upon plans marked definitively in their leases. The terms vary excessively, according to the locality and the soil. A common plan is, for the colonist to receive one quarter of the gross produce, after the quantity used as seed has been abstracted from it. For this he is bound to perform the following portions of the labour, viz. the levelling the surface, the sowing, the weeding, the reaping, and all the labour not performed by cattle, until the crop is placed on the threshing-floor. In the case of some of the poorest land, the colonist receives one third, instead of one fourth, of the produce. About midsummer-day the water is allowed to run off the land, and during eight or ten days it is suffered to become dry. This is done to destroy the numerous water insects, which would prove injurious to the roots of the rice, and cause it to fall into the water.

Some few persons have, however, of late abandoned this practice of letting off the water, and say it is advantageous to the perfecting the grain. In common cases, at the end of this drying, the field is again covered with water, and it continues until the time of harvest, which is usually the first week of September. It is reaped, bound in sheaves, and carried to the threshing place, where it is commonly trodden out by horses. When the rice has been trodden out, it is exposed to the sun to dry it for a few days, and carried to the place where, by stamping in a kind of mortar with wooden pestles, it is cleared from the husks, which are separated from the grain by appropriate sieves, through which it is frequently poured. If the rice is very good, it yields, when stamped, about one half the measure it did in the raw state. If it yield but one third, it is considered as scarcely marketable. The product of rice, as far as can be gathered from the returns of the crops in various years and various localities, is surprisingly different, and there seems to be no means of forming any approximate average. The following are all the acts that could be collected on the subject.

Places.	Lowest Quantity per Acre in Bushels.	Highest Quantity per Acre in Bushels.
San Novo	$51\frac{5}{10}$	96
Tavezzano	$54\frac{3}{10}$	$102\frac{3}{10}$
Viltadoni	46	$120\frac{1}{2}$
Ronearo	44	82
Verona	35	$47\frac{1}{2}$
Ditto	33	46
Grigolate	$29\frac{1}{2}$	51

These are the quantities of rice before it was cleaned from the husks, and from which one half must be deducted, to give the produce in marketable rice.

Wheat is a grain cultivated upon a small scale in most parts of Lombardy, excepting in that portion of it which comprehends the mountainous Alps. It is not, however, a plant which succeeds to the same extent as it does in climates somewhat colder. There is but one species of it sown in the whole of the province. It is a winter wheat, sown between the first week of October and the first week of November; but the best farmers wish to finish their sowing by the 21st of October, if the season permit. The wheat is all of the bearded kind, the preference of which has been owing to the opinion that the beard is a protection against the fogs of the blooming season, and against the depredations of the small birds at the time of the grain ripening. The produce is a kind of wheat harder than that of the west and north of Europe, but less hard than some of the wheat from the Black Sea. From this circumstance it is better calculated to be converted into maccaroni than our wheat would be, for which purpose it is much more frequently pounded in a mortar than ground at a mill. The product of the crops is less per acre than it is generally in the German dominions of Austria, and considerably less than in England or in the best parts of the Netherlands.

It is of course most productive on the best lands of the rich provinces, where irrigation is practicable to the exact extent which the nature of the crop may require. On that description of soil it is less profitable than other crops, and, therefore, only a small portion is applied to its growth; but even on the best of that land it is a rare event to obtain sevenfold the quantity of the seed that has been sown. On the farm of Tavezzano, one of the best cultivated in the province of Lodi, the average produce of the wheat land in the past year had been twenty-four and a third English bushels the acre. In the farm of Viltadoni, near to it, the report was, that three and a fourth bushels per acre had been sown, fifteen and a half reaped. Berra, in his work (*Sull' attuale Avvilimento del Prezzo di Grani*) published in 1826, calculates the increase of wheat in the dry parts of Lombardy to be only at the rate of four and a half times the quantity of the seed. In plain figures reduced into English measures, he averages the seed sown to be two and a fourth bushels per acre, and the crop gathered nine bushels and three fourths. The late Count Dandolo estimates the produce higher, and concludes that, with the common culture, the increase of wheat is about five times the seed, or that three bushels an acre are sown, and fifteen bushels reaped. He does not state what the increase had been on his own land, which was highly cultivated; but it appears, without being informed whether he sowed thicker or thinner than his neighbours, that he usually had a crop of twenty and a half bushels. In the neighbourhood of Mantua, where the poor colonists grow wheat and maize in alternate years, where the soil is sandy, and where, from the paucity of cattle, little manure is applied, it does not appear that the crop of wheat grown more than equals four times the seed. In some of the other provinces of the part of Lombardy within the government of Milan, as well as in some of those in the Venetian government, the report of the officers employed in making a new valuation or cadastral, and who had been occupied three years in examining the state of the produce for financial purposes, was obtained. As it was the business of these officers to examine only the produce, no proportion is stated between the quantity of the seed and that of the result.

In Verona, the higher part of which is stony, and the lower part sandy, the best of the land yields ten bushels, and the worst only six and a half. In Vicenza, where the soil is better, the lands of the first quality yield eighteen bushels, those of the second fifteen, the lowest twelve. In Padua, the first class of lands yields fifteen and a half bushels, the second eleven and a fourth, and the lowest class only seven bushels. In Udine, a poor sandy soil, mixed with many pebbles, and where there are but few cattle, the first class of soils yields ten and a half bushels, the second nine, and the lowest only six and a half.

It is not easy to ascertain what portion of the fields is appropriated to the growth of wheat. It appears by the appendix, that the whole land under the plough is 1,461,700 English acres; of this portion, 125,000 acres are cultivated with rice. On the best of the soils, according to the regular rotation of crops, one half of the land is in grasses, the proportion of maize is greater than that of wheat, and some portion is sown with pulse, rye, millet, oats, flax, hemp, and other kinds of crops. The whole portion sowed with wheat does not probably exceed 200,000 acres, and the best judges estimate that such is nearly the extent. If, then, the crop be calculated to yield on the average two quarters to the acre, it will afford 400,000 quarters. If from this be deducted what will be required for seed, being about a fifth, or 80,000 quarters, it will leave as food for 2,500,000 persons, at the rate of little more than one bushel for each, or about one eighth part of what is usually considered as the annual consumption of each individual in England. From the great articles of human consumption being so different, a comparison seems unnecessary; but it may serve to illustrate a general principle of great importance, viz. that consumption and production so act upon each other as constantly to tend towards an equilibrium. Hence we may infer, that few countries extend their growth of articles of the first necesssity far beyond what their own population require.

The other kinds of grain are but very little cultivated. Barley and oats are scarcely needed. They are never used as human food, and neither is any beer brewed, nor any corn-spirit distilled. A little rye is grown upon some poor districts, but it yields a very low price, and the quantity sown is every year diminishing, as the taste of the people changes in favour of maize. Millet is grown, but is not deemed a profitable crop, except occasionally, when it comes to maturity, which it sometimes does if sown in stubble after the harvest. Buck-wheat is known only in or near the Alpine districts, and is but slightly attended to.

The plants which do not serve for food are not of any great importance. Though flax is grown chiefly for the employment it gives in spinning and weaving, yet some oil is made from the seed, as also from rape, and the seed of other plants of the brassica kind. The hilly regions abound with several kinds of nuts; and chestnuts form an important portion of the sustenance of the poorer classes of the inhabitants. The walnuts and hazelnuts are converted into a fine oil, much valued by painters; but the demand for it, as well as the supply, has been gradually declining of late years. Scattered olive-trees are to be seen in most places between the hills and the lake of Garda, and a few olive gardens on that and the lake of Como; but the quantity of oil expressed from them is very insignificant. As none of the trees have been planted within the last sixty years, their number has diminished, and is still constantly diminishing. The inducement to extend the growth of mulberry trees and of vines is so much more powerful than exists with regard to olive-trees, that the latter are almost neglected, and more especially as the parts of Italy to the south of Lombardy in contact with it have a more genial soil and climate, and can render olive-oil upon more beneficial terms than it could be produced if much extended within that territory.

Few things are more striking to a visitor in Italy from the north of Europe, than the straight rows of trees of all kinds that run through the corn fields, at the foot of which vines are planted and trained, so as to extend in elegant festoons from one tree to another, exhibiting the pendant clusters of grapes. If the same mode of training the vines were attempted in the somewhat colder climates of France and Germany, it is thought the shade of the trees would prevent the grapes from ripening. This effect is not produced in Lombardy, where the berries become ripe, and, when eaten, are of good flavour; but the wine produced from them is in general of a bad or very indifferent quality. Though much of the wine is produced from such vines in the corn fields as are distinguished by the names of *Campi Arative Vitati*, or of *Campi Arborati Vitati*, and others from vines planted in rows at such a distance from each other as to admit of maize being grown between them, and called *Ronchi;* yet in some parts are vineyards properly so called, because, like those of France and Germany, they alone occupy the ground, and are, like them, supported by props. The greater part of the best wine, however, is produced from the *Ronchi.*

The wine generally in Lombardy is of a very bad quality, which is attributed to its production being left almost exclusively to that description of cultivators before noticed under the name of colonists. These exercise little discretion and little care, either in the choice of the kind of grapes they plant, or in the management of the juice when it is expressed from them. Their chief care is to obtain the largest quantity, without much regard to the flavour or the aptitude of keeping; and commonly, as soon as it is made, they divide it in equal shares with their landlords. One cause to which the inferiority of the wine is attributed arises from the general predilection in favour of red wine, or, as it is called, *Vin Nero*, which is prized according to the darkness of its colour. In order to produce this deep colour, the skins of the grapes are left, in the first part of the process, to ferment with the juice. Sometimes this is suffered to continue during eight or ten days in a vat before the liquor is drawn off, and sometimes still longer, as the longer it continues the darker the wine becomes.

There is no old wine in Lombardy, except, perhaps, in small quantities in the hands of a few amateur proprietors. The wine of each vintage is sold in the course of the following year; and when any of it is kept, even though it should not have become, or show a tendency to become, vinegar, it will sell at a lower price than new wine, because it is milder, and more agreeable to the taste of the consumers. It would be as difficult to estimate the quantity of wine made annually in Lombardy, as it would have been fifty years ago, if no duty had been paid on malt, to have calculated the quantity of malt liquor of all kinds made in England; at which time almost every family out of London brewed its own beer. From a long list of the number of vines, and their produce in wine, of several farms of various soils, around the corn-fields of which the vines had been trained to the trees, it appears that in the most productive, the highest produce was 122 gallons from 100 vines; that in the least productive year, from that number of vines only thirty-three gallons were produced; and that on the average of thirty-one such farms, every 100 vines yielded fifty-one and a half gallons of wine.

In the vineyards properly so called, the vines are, like those of France and Germany, supported with sticks. Each vine, of course, produces less than those trained from one tree to another. From a return of the produce of fourteen such vineyards, it appears that the quantity yielded by the lowest was thirty-two gallons, and the average of the whole seventy gallons to the acre. As wine is not an article of export from the province of Lombardy, but, on the contrary, much is imported from the other parts of Italy, and, for the few who indulge in such luxuries, some from France and from Germany, it has been looked upon, whilst drawing up these notices, purely in an agricultural point of view. It would have been easy to have given more details respecting the preparation, but it seemed to be more proper to leave that part of the subject to such persons as may be employed in writing the history of vines, than to enter into it in this place.

Potatoes, which form so important a part of the food of the inhabitants in the more northern parts of Europe, are very little cultivated in Lombardy. They are almost exclusively confined to the Alpine districts, or, when grown on the level country, are confined to the gardens. The absence of this root is a subject of sincere regret to the most patriotic individuals who have devoted their attention to rural economics. Count Dandolo attributes much of the dreadful consequences which followed the deficient harvests of 1816 and 1828, when great numbers perished from want of common necessaries, to the absence of that seasonable supply of food which potatoes would then have furnished. Others have made similar and ineffectual remarks. The taste for polenta is much too deeply rooted and the dislike to potatoes so common amongst the working classes of the rural districts, that there is no present prospect of their cultivation being speedily extended.

Specification, from an official Document, of the Appropriation of the Cultivated Lands in Lombardy, in the year 1831, *rendered into English Acres.*

Delegations or Provinces.	Arable Land.	Rice Land.	Meadows.	Gardens and Orchards.	Vineyards.	Upland Pastures.	Woods.	Total.

The most important tax is the territorial impost. It is an ancient payment, which has been alike collected under the several changes of rulers which have administered the finances of the country. It has resisted all general attempts to equalize its rate according to the productive powers of the soil, and therefore falls in a very unequal degree upon different estates. Attempts have been constantly making, and still are in progress, to equalize this impost; but the pace of the commissioners appointed for the business is so very slow, that no one can form an opinion of the period at which the work will terminate. It will not be possible here to give more than a general view of the amount of this tax. The province of Milan extends over 16,500 square miles. Of this, the roads and the water are 730, and of the remainder, one quarter is estimated to consist of sterile rocks, of miserable pasture, or of more miserable woods, yielding no produce worth collecting. This would leave of all descriptions of valuable land to the extent of 11,830 square miles, or about 7,370,000 English acres. The whole amount of the tax is 26,171,338 lire, or, taking the lira as the thirtieth part of a pound sterling, is L.872,374, or about 2s. 2d. per acre. In estates in the province of Lodi the amount of whose tax is clearly stated, it amounted in one instance to 3s. per acre, in others to 2s. 10d., in most to 2s. 6d. In the province of Pavia it amounted in one instance to 7s. per acre, in others to 6s. and in several to 4s. 6d. In the province of Milan some estates near the city were made to pay as much as from thirty-eight to forty-one and a fourth per cent. on the actual rent. The estates here referred to were the best land, and the best cultivated; and those he highest taxed were in that condition when the last survey was made. These prices, so high above the aveage, make up for the little value of the extensive parts of he poor land of the other and larger six provinces. As his impost is collected in all cases from the proprietor, it s regularly paid, and attended with little cost in the collection.

It is generally believed that more than five sixths of the nhabitants of Lombardy subsist wholly by the labours of he field. Of these, the far greater proportion are of the decription which is here called colonists. They are small occupiers, dividing the trifling products of the soil with the proprietors. Their condition is far worse than that of day-labourers in this country, for they have no resource in case of a deficient harvest but beggary or starvation. Their dwellings are small and miserable; they are without furniture, utensils, or the means of cleanliness. They generally marry early, and have families, though they have no prospect of supporting them, beyond the hope that the half of the produce of maize on an acre of land may yield them food during the year, with the exercise of the greatest parsimony in its use. In the event of sickness they have no relief; and their clothing is deficient, and of the coarsest materials. The charity of those who can afford it is bestowed with as fair liberality as can be expected, considering the numerous claimants that offer for its reception. The worst part of this picture is, that no hope is entertained of bettering their condition, and no means of doing so attempted to be put in practice, either by public bodies, such as monasteries, which formerly existed, or by the government, or by private associations of individuals.

The mining operations are inconsiderable, and are confined to the procuring of iron in the Alpine valleys of Bergamo and Brescia, and of copper in Belluno.

The manufactures of Lombardy are extensive; that of silk gives the most employment, but very large occupation is afforded by the linen and woollen trades, and in both those branches the use of machinery has been widely diffused. Woollen goods of almost every description are made in the delegations of Venice, Padua, and Como. Milan has been from remote times celebrated for its weapons and arms, and iron work of all kinds is still extensively made in the delegation. Besides the great branches of manufacture, most of the smaller ones are carried on, especially those of paper, glass, gold and silver articles, and domestic utensils.

The foreign trade is not material; that of Venice has much declined since its union with Austria, though some of the smaller articles of that division are still dispersed throughout the eastern countries. There are still many ships navigating the Adriatic and the Mediterranean Seas, now bearing the Austrian flag, which are built and equipped at Venice, and at the other ports under the dominion of that power. The following table will show the extent of the foreign trade.

An Account showing the Value of Goods Imported and Exported in 1824.

	Imports.	Exports.
Groceries, including coffee, sugar, and spices	7,163,737	185,966
Drugs	1,129,308	244,539
Paints and dyers' colouring articles.	1,544,745	66,243
Cattle of all kinds	10,275,481	728,120
Wines, liqueurs, spirits, and eatables	15,011,384	1,413,544
Wool, hair, and goods made thereof	1,042,311	2,502,819
Flax, hemp, and goods made thereof	1,585,002	368,494
Skins of animals, and goods made of them	2,188,573	151,718
Wood and wooden-ware	1,158,002	293,080
Metals and metal articles, except iron	161,621	369,801
Various others, most small wares...	5,387,803	1,508,596
Silk and manufactured silk goods...	1,716,130	64,290,939
Corn and pulse	2,319,189	3,085,729
Cheese	633,910	3,513,043
Linen, yarn, and twine	208,536	3,094,694
Cotton and cotton goods	2,815,529	179,075
Iron and iron goods	106,207	1,212,869
	54,447,768	83,209,320

Note.—The above account is made up in lire, of which thirty are about the value of the pound sterling; according to which, the excess of the exports beyond the imports amounts to L.958,000 sterling.

The government is almost an unlimited monarchy; for although, by the constitution of April 1815, there are both central and provincial assemblies of representatives of the people, their function is rather to form rules for the execution of the laws promulgated from Vienna, than to contribute any share in making such laws; and though they may make representations against them, they have no power to prevent or suspend their operation. The kingdom of Lombardy is ruled by a viceroy, who resides at Milan, and enjoys a salary of about L.40,000 yearly. Under him are the governors of the two divisions into which the kingdom is formed, viz. Milan and Venice.

The revenue of the kingdom is derived in part from national domains and royalties, part of which once belonged to the church, a heavy tax upon tobacco, with some other direct and indirect taxes. The gross sum extracted is about L.2,000,000; but the collection is expensive, and the interest of the local debt is paid off it, so that not one fifth of that amount reaches the imperial treasury. There are also local taxes, which are collected and dispensed by the municipal authorities of the cities and towns. By some recent laws, all taxation on commodities passing from this kingdom into the other Austrian dominions have been abolished, and commerce between them is free. A military board has the direction of the army, and of the several fortresses, with their stores and garrisons. Six regiments of infantry and two of cavalry are recruited in this part of the empire.

The chief or head of the ecclesiastical body is the patriarch of Venice, under whom are the archbishops of Milan and Udine, with seventeen suffragan bishops. The institutions for education are, the universities of Pavia and of Padua, medical and surgical colleges at Milan, lyceums at Bergamo, Brescia, Como, Cremona, Mantua, Vicenza, Treviso, and Udine. The promotion of the higher branches of science is achieved by learned societies in most of the cities, the most eminent of which are those of Milan, Venice, Padua, and Verona.

The naval force of Austria is constructed and equipped in this kingdom. It consists of eight ships of the line of seventy-six guns each, seven frigates of forty-four guns, one corvette, eight brigs, and six schooners, mounting together 1064 cannon. Besides, there are several vessels on the stocks, but their building proceeds in a dilatory manner. Most of them are at Venice, but some are stationed at Trieste, Cattaro, and Zara. The commissioners who regulate naval affairs meet at Venice. There is a corps of naval engineers, and a battalion of infantry who serve as marines. (G.)

LOMBES, an arrondissement of the department of the Gers, in France, extending over 343 square miles. It comprehends four cantons, divided into ninety-nine communes, and contains 39,700 inhabitants. The capital, of the same name, is situated on a fertile plain, through which the river Save runs, and contains 300 houses, with 1590 inhabitants. Long. 0. 49. E. Lat. 43. 28. N.

LOMONOZOF, a Russian poet, and a great improver of his native tongue, was the son of a dealer in fish at Kolmogori. He was born in 1711, and was fortunately taught to read; a rare circumstance at that time for a person of his condition in Russia. His natural genius for poetry was first kindled by the perusal of the Song of Solomon, translated into verse by Polotski, whose rude compositions, perhaps scarcely superior to our version of the psalms by Sternhold and Hopkins, inspired him with such an irresistible passion for the muses, that he fled from his father, who was desirous of compelling him to marry, and took refuge in the Kaikonospaski monastery at Moscow, where he had an opportunity of indulging his taste for letters, and of studying the Greek and Roman languages. In this seminary he made so considerable progress in polite literature, that he was noticed and employed by the Imperial Academy of Sciences. In 1736, he was sent, at the expense of that society, to the university of Marpurg, in Hesse-Cassel, where he became a scholar of the celebrated Christian Wolf, under whom he studied universal grammar, rhetoric, and philosophy. He continued at Marpurg four years, during which time he applied himself with indefatigable diligence to the study of chemistry, which he afterwards pursued with still greater success, under Henckel, at Freyberg, in Saxony. In 1741 he returned to Russia; in 1742 he was chosen adjunct to the Imperial Academy; and, in the ensuing year, he was elected a member of that society, and professor of chemistry. In 1760, he was appointed inspector of the seminary then annexed to the academy; in 1764 he was gratified by the empress with the title of counsellor of state; and he died on the 4th of April that year, in the fifty-fourth year of his age. Lomonozof excelled in various kinds of composition; but his reputation is chiefly derived from his poetical compositions, the finest of which are his odes. His poetical and miscellaneous pieces appeared in three volumes; and he also published two small works relative to the history of his own country. The first, styled Annals of the Russian Sovereigns, is a short chronology of the Russian monarchs; and the second is, the Ancient History of Russia, from the Origin of that Nation to the Death of the Great Duke Yaroslaf I. in 1054.

LONDON.

This city, the metropolis of the British empire, is situated on both banks of the Thames, if the name be taken collectively, and in that sense, though chiefly within the county of Middlesex, includes a part of Surrey, and, for purposes of criminal judicature (by the act of William IV, called the Central Criminal Court Act), a portion of the counties of Essex and Kent.

Like most cities, the early history of this is lost in the obscurity of remote ages. The first notice of its existence to which implicit credit can be given is that in the Annals of Tacitus (lib. iv), who says, "Londinum cognomento quidem coloniæ non insigne, sed copiâ negotiatorum et commeatuum maxime celebre." The derivation of the name of this city has been variously traced, and though it must remain a matter of doubt, we state that which seems the most probable.

Llin in the Celtic or ancient British language signified a lake, and *din* a town or a harbour for ships. As until recent dates the Surrey side of the river was often a lake in some parts, and a swamp in others, the name might be easily changed from Llindin to London, and be descriptive of its local position. It could not, however be a place of very great importance at the time of the invasion of England by Julius Cæsar, for though that commander must have passed near it, he has not noticed it in his Commentaries.

The Romans, who appear to have taken possession of this city under the Emperor Claudius, about 100 years after the invasion of Cæsar, gave to it the name of Augustus in honour of that prince. Under the Roman government it was erected into a praefecture, and the inhabitants, though the name of citizens of Rome was conferred upon them, were not allowed to be governed by their own laws, but by military magistrates sent annually from Rome. It must then have acquired some degree of importance, because, in several of the *itinera* of Antoninus, the roads are described by him as beginning or ending at this place. The doubts respecting the author of the *itinera*, and the time when they were drawn up, make this inference of less authority.

It seems certain that, under the Romans, London was not fortified at an early period of their occupation; for when the Britons revolted against the Romans, and were led by their Queen Boadicea, she captured the city and burned it, after a general massacre of the inhabitants. It continued still without fortifications, till, according to Woodward, the reign of Constantine, or, according to Maitland, till the governorship of Theodosius, in the year 369. The great number of coins of Helena, the mother of the Emperor Constantine, which have been found under the walls, give the greatest degree of probability to the opinion of the former of these authors. It was certainly erected into an episcopal city by that emperor after he had been converted to the Christian religion; and that increases the probability of the opinion that he constructed the walls, for all the sees of bishops were originally within fortified places.

Whatever may have been the date of the erection of the walls, the limits to which they then extended may now be ascertained by the concurrent testimony of all the antiquarians, and by the ruins of the foundations and of parts of the wall which have been traced out within very recent periods.

A fort on the site now occupied by the Tower of London, formed the commencement of the defences. A wall was extended from it through the Minories to Aldgate, whence it proceeded between Bevis Marks, Cammomile Street, and Houndsditch, across the churchyard of Bishopsgate to Cripplegate. It then took a southerly course to Aldersgate, from which it run south-west by the back of Christ's Hospital and Old Newgate, and passing behind the present prison of Newgate and Stationers' Court, reached Ludgate. From that gate it proceeded westerly by Cock Court to the river Fleet, now New Bridge Street, and terminated at a fort called afterwards Barnard's Castle. It was also then covered by another wall along the bank of the Thames, which, however, was destroyed at a very remote period. The extent of the wall, exclusive of that by the side of the river, was two miles and one furlong; that on the bank one mile and a tenth. The height of the walls was twenty-two feet, and they were defended by fifteen lofty towers. Through some of these were the great roads leading to the different parts of the kingdom. The praetorian way, or the Watling Street, passed under Newgate, and then turned towards the river, where was a ferry connected with the road to Dover. The Hermin Street road passed under Cripplegate. Another passed through Aldgate and proceeded by Bethnal Green to the old ford over the river Lea, and on towards Essex, Suffolk, and Norfolk. In process of time other roads were laid out, when the gates corresponding to them were erected and received the names of Bridgegate, Ludgate, Aldersgate, Moorgate, Bishopsgate, and the Postern on Tower-hill.

It is probable that, after the Romans had been induced to withdraw their forces from England, and left it exposed to the ravages of the northern tribes of Picts and Scotch, London was not much improved or extended. When the Saxons had fixed themselves in the country, and assumed something approaching to a regular government, the city, which had suffered severely during the contests between the Britons and the invaders, soon recovered its former rank, and acquired new importance; so that at that period the Venerable Bede writes of it as a princely town of trade under the rule of a chief magistrate, whose title of portgrave or portreeve conveys the idea that its commerce by water must have been for the time so great as to require magisterial superintendence.

During those civil wars which the new Saxon masters of England carried on against each other till the several kingdoms were united under one head in the person of Egbert, in 819, the city of London, if it did not maintain a neutrality, seems to have sufficiently increased in importance to induce that prince to make it the capital of his whole kingdom; which it has continued to be ever since that reign.

Soon after this the Danes began their nautical predatory excursions, and at length, after attacking the northern ports of the kingdom, in 849 entered the Thames with 250 vessels, seized upon London, plundered and then burned it, and exercised their savage cruelties on the inhabitants. A second attempt by some piratical people was made, and with greater force, about two years after; but on this occasion, King Ethelwolf and his son Athelbald collected a sufficient force to disappoint and finally to overcome the invaders, though the returning prosperity of London received a severe check by the attempt.

In the reign of Alfred the Great, London soon began to recover from the ruinous condition in which the attempts of the Danish invaders had left it. He restored the ruined defences, expelled those of the Danes who had been settled there, affirmed the privileges which had been conferred, added to them others, and contributed much to ornament the whole city. Having made it a place of security by its walls, and capable of a powerful defence, it was placed under the government of his son-in-law, Ethelred duke of Mercia. In this condition it was, when, in 893, an accidental fire bursting forth spread with unextinguishable fury, and the houses being wholly constructed of wood, became at length a prey to the flames. As the walls were uninjured by the conflagration, the security they afforded encouraged the government and the inhabitants to restore their losses with great expedition. The city was first divided into wards, and magistrates were appointed to each, who then bore the name of sheriffs, a title which had been first created for those who exercised the authority of the monarch in the several districts into which he had divided the whole kingdom. In the portreeve and those sheriffs are to be found the first traces of that system which, with some variations, has continued to regulate the affairs of the city to the present time. As soon as Alfred had settled the general state of his dominions into moderate tranquillity, his attention was drawn to the capital, and the spirit he inspired was speedily exhibited in London. The new houses were constructed with more solidity, and with greater skill and ornament. The chief material used in the buildings was still wood, but some of the nobility were induced by the king to erect houses within the walls of the capital in which stone or bricks were used, and a few of the more wealthy citizens followed the example thus shewn to them; but still the number of such buildings was small in proportion to the whole. At that time thatch was the universal covering.

England had rested from the ravages of the Danes more than a century, when, in 1013, the King of Denmark, Swend, called by English writers Sweyne, or Sweno, aided by Olaf Tryggvason, King of Norway, undertook the subjugation of the whole kingdom. The Danish monarch landed in the Humber with a powerful and splendid armament; and leaving his fleet there under the command of his son Kund or Canute, marched his forces into Wessex, which he laid waste and subdued. Ethelred then abandoned his palace and capital, and sought refuge in the Isle of Wight. The burgesses of London opened their gates to the invader, who was acknowledged as their king by the Anglo-Saxons; and Ethelred, who had married Emma, daughter of the Duke of Normandy, repaired for safety to that country.

Although war was still carried on in the kingdom by the Danes under Canute, who had succeeded to the power of his father, and by the Anglo-Saxons under the Prince Edmund Ironside, the result was so doubtful, that a compromise was entered into by the two commanders, by which Canute secured his power over the city of London, and was acknowledged and received there as the lawful sovereign. Canute, then, as master of the whole kingdom, imposed upon his subjects a tax to pay his army, amounting to L. 72,000, of which L. 10,500 was to be paid by London. As far as the combined wealth and the population can be measured by the amount of taxation, London might then be considered as constituting one-seventh part of the whole kingdom, and this is nearly the proportion which it has borne from that time to the present day.

On settling the succession to the crown, after the death of Canute in 1046, the English supported the son of King Ethelred, or, on default of him, Hardicanute, a son of Canute, by Queen Emma; whilst the citizens of London espoused the claims of Harold Harefoot, a son of Canute by the Queen. Edward's party speedily declined, and the two half brothers remained the sole competitors. Hardicanute repaired early to England; and an assembly, or *wittenagemote*, was convened at Oxford, consisting of all the nobles to the north of the Thames, at which Harold was raised to the throne. At this assembly, where nobles only were admitted, the pilots of London, comprehending probably those who were the chief merchants, also held a meeting, and no important affairs were resolved upon without their consent. Some have represented this as the first instance of London having sent members to a legislature; whereas it seems to have been more like an aristocratic assembly, to which chartered citizens, forming a kind of commercial nobility, were admitted.

After the defeat of the Saxons, at the battle of Hastings, the city of London tendered a ready submission to William the Norman, who confirmed to them the privileges which former monarchs had bestowed, and granted additional power by two new charters. The city was tranquil and prosperous; but it received a severe check by a fire, which consumed a great part of the houses in 1077; and by another, nine years afterwards, when the new buildings, as well as the old, were consumed together. The fire of 1086, which began near Ludgate, burned the cathedral of St Paul's, which, however, was soon rebuilt, with more than its former magnificence.

During the reign of the second William, the prosperity of the city was in some measure checked by the exactions he enforced, but in a greater degree by several fires, some violent hurricanes, and extensive inundations. Henry, who succeeded, granted several immunities to the city, which tended to increase its commerce; and he especially restrained the rapacity of the Norman barons, and prohibited within the walls the insolent conduct which they had practised to an enormous excess. The city continued to flourish under Stephen, and his turbulent reign; though, for his own warlike purposes, he exacted large sums of money. The prosperity of the city seems to have begotten internal disorders. Many confederacies were formed, in which some of the rich citizens engaged, to commit robberies, and even murders, in the night time. For these the inhabitants were made to pay a fine of five thousand pounds, and one of the conspirators, a rich man of the name of Senex, was hanged, though an offer of five hundred pounds weight of silver was made to save him from the gallows.

Henry II. changed the title of portreeve for that of bailiff; and that officer claimed, as a matter of right, the performance of the duty of butler at the subsequent coronation of Richard I. In 1191, the bailiff assumed, or was granted, the title of mayor; and the following year Henry Fitz-Alwene, who then filled the office, issued orders in his own name, jointly with that of the aldermen, for the prevention of fires. By this document it was commanded that "all houses to be erected in London hereafter, whether in the city or in the liberties thereof, should be built of stone, with party walls of the same; and should be covered either with slates or tiles, to prevent those dreadful calamities which were frequently and chiefly occasioned by houses built with wood, and thatched with straw or reeds." For this purpose it was also provided by the more discreet men of the city, that "twelve aldermen of the city should be chosen in full hustings, and there sworn to assist the mayor in appeasing contentions that might arise among neighbours in the city, upon inclosure betwixt land and land, and to regulate the dimensions of party walls, which were to be of stone sixteen feet high and three feet thick; and to give directions about girders, windows, gutters, and walls." In 1198, Richard, who placed confidence in the wisdom and fidelity of the city of London, when resolved to fix a standard of weights and measures for the whole kingdom, committed to the sheriffs of London and Middlesex the execution of his plan; and they were charged to provide measures, gallows, iron rods and weights for standards, which were to be sent to every part of the kingdom.

King John, who succeeded Richard, conferred additional favours on the city of London, by several charters which were granted in his reign. He first confirmed former grants, and conferred on the citizens the privilege of entering his foreign dominions free from all tolls and taxes; a matter of considerable advantage in the commerce with

Normandy, whence wine was imported, and to which English wool was exported. This was, however, an affair of bargain, as the king was paid for the privilege one thousand pounds weight of silver. By another charter the citizens of London had conferred on them the jurisdiction and conservation of the river Thames, and an additional grant of the same right over the river Medway. A third charter conveyed to the citizens the power of choosing their sheriffs, who had before been nominated by the crown, and also invested them with the right of shrievalty over the county of Middlesex, and valuable fee-farm rents, of which they had been deprived under a former reign.

Henry III. made several attempts to encroach upon those privileges which his predecessors had conferred upon London; and this conduct was productive of many serious disturbances both in London and in Westminster. They were suppressed by violent and arbitrary measures, and at length the whole nation was in a state of alarm, when the parliament interposed, and induced the king to redress, or promise to redress, the most severe of the grievances that were the subject of complaint; but, with respect to the city, the charters were renewed, and the rights and privileges of the citizens confirmed. At this time the right of using a common seal was granted. The king, however, during his whole reign, continued to exact money from the city.

During that long reign of fifty-six years, though the city was sorely afflicted with two years of famine, first in 1258, when, according to Fleetwood, many people were starved, and again, in 1270, when, according to the same authority, "provisions were so scarce, that parents did eat their own children," and wheat was sold at a price, equivalent in our money to thirty-six shillings the bushel; London on the whole continued to increase, but was disgraced, if not retarded, in the progress of its foreign commerce, by the cruelties and plunderings which were exercised towards the Jews who had settled there.

In the reign of Edward I. the city was first divided into twenty-four wards, each of which was then allowed to choose common councilmen and an alderman. Under Edward III. the city received some additions to its authority, the most eminent of which was the perpetual right of magisterial supremacy over the borough of Southwark. An epidemic disease, or kind of plague, proved a calamitous visitation to London. It first became apparent in 1348, and was said to have been imported from the East. Its ravages were so extensive, that it is related in the chronicles of the time that more than 50,000 persons became its victims; and it did not altogether disappear till it had been nine years the source of grief and anxiety.

In the year 1380 the insurrection of Wat Tyler alarmed the city, but was soon suppressed without much difficulty. It is stated to have been put down by the zeal of Sir William Walworth, the lord-mayor, who stabbed the leader of the *jaquerie* in Smithfield. In commemoration of this event the dagger was added to the arms of the city.

The first illuminations in the city took place at the coronation of Henry IV., and, after the victories of Henry V. in France, they were again repeated; from which time London began to be lighted at night by lanthorns.

The latter part of the reign of Henry VI. was disturbed by insurrections in several parts of the kingdom; the chief of which, as affected London, was that in Kent under the guidance of John or Jack Cade. He collected a body of 20,000 men, and having obtained some slight success over the Sheriff near Sevenoaks, he advanced to London, which opened its gates to admit him, whilst the king fled to Kenilworth. At first some order was preserved by Cade; but he found himself unable to repress the riotous disposition of his followers. All became confusion among them; and the leader being killed, and several of his followers executed, the suppression of the revolt was the speedy consequence. This event occurred in 1450, and it was soon followed by the wars between the houses of York and Lancaster. In this contest, the city of London chiefly favoured the interests of the latter family; and, after the battle of Barnet, Edward IV. bestowed the honour of knighthood on the mayor, the recorder, and twelve of the aldermen. In this reign occurs the first notice to be found of bricks being used for building London. They were burned in Moorfields. It was also the era in which the first printing-press was constructed and worked by Caxton; and about the same time, the cisterns and conduits for supplying water, in several parts of the city and suburbs, were erected.

In the reign of Henry VII. a nondescript disease, called the sweating sickness, generally prevailed in England, but especially in London, where it appears that two mayors and six aldermen, with numerous other citizens, fell victims to this disease. Notwithstanding the very extensive spoliations committed on the city by the king and his favourites, Empson and Dudley, some considerable improvements were made. The chapel at Westminster, bearing that monarch's name, was commenced; the river Fleet was rendered navigable to Holborn Bridge; and an artillery-ground for the practice of archery was established.

In the reign of Henry VIII. the city successfully resisted the attempts of that monarch to extort money without the authority of Parliament. Many improvements were made, to which the suppression of several of the religious houses contributed; nor were these much impeded by the religious persecutions sometimes directed against Catholics, and at others against Protestants.

In the short reign of his son Edward, London was permanently benefited by the establishment of the great hospitals of Christ's, of Bridewell, and of St Thomas's.

Owing to the wise conduct of Elizabeth and her ministers, the prosperity of London advanced during the whole of her reign. The great number of intelligent and wealthy persons who took refuge there from the cruel wars carried on in the Netherlands, and who were protected by the government, generated a spirit of industry and order amongst all classes; and they introduced numerous manufactures before unknown in England, which conferred benefits upon the whole kingdom, and especially upon London, which was the chief point from which the trade was carried on. She, as well as her successor James, was averse to the great increase that was going on in houses and inhabitants in London, and both issued unavailing proclamations to prevent its growth. As abundant materials of that period are now extant, it may not be uninteresting to sketch from them a short description of the extent of metropolis which created serious uneasiness to the government of that time, and to enable the reader to contrast the state of the city at that period, with the appearance which it now exhibits.

Extent of the city.

By some apparently correct maps of the reign of James I. it may be seen that the chief part of London was along Newgate Street, Cheapside, the Poultry and Cornhill, and the various streets and alleys leading from them to the banks of the Thames. Except in Coleman Street and a few scattered houses in Lothbury and Bishopsgate, all the way lower down was garden-ground or fields. There was an irregular street from Bishopsgate to Shoreditch Church, with open fields behind the houses; and Houndsditch was a single row of houses, looking on the city walls, with open fields behind them. What is now Goswell Street was then called the St Alban's Road, with a few houses. Clerkenwell consisted chiefly of the monastery, the gardens, and buildings which had belonged to the church; and thence to Gray's-inn-lane was open field, with a few gardens. From Holborn Bridge to Red Lion Street there were houses on both sides; but they ceased there; and the road to the small village of St Giles's had hedges on both sides, and still

London.

has the addition, "in-the-fields," to its name. To the northward and westward of this spot, all was open field, excepting on the road to Oxford, on both sides of which were hedges and a few trees. Tyburn was then a hamlet two miles from London. A road proceeded from the road to Oxford, and joined that leading to Reading, opposite to what had been the hospital, but subsequently the palace, of St James's. There were a few houses near St Martin's Church, in the way to the garden of the convent; but Leicester Square, Long Acre, Seven Dials, and Drury Lane were open fields.

Along the Strand were houses on both sides, but those to the south were chiefly palaces of the nobility, with gardens behind them extending to the river. These were in the occupation of the peers, whose names have been given to the streets which have been built on their stately mansions, viz. Northumberland, Salisbury, Arundel, Cecil, Norfolk, Surrey, Villiers, Buckingham, and Essex. Each of the noble owners kept barges, with watermen in splendid liveries, to convey them either to the city or to the court at Whitehall, or to visit at Lambeth or Chelsea.

Spring-gardens were a series of walks extending to the palace of Whitehall, whence to the Abbey there was a regular street, and a few beyond, facing the water, near the spot on which Abingdon Street has since been built.

On the Surrey side, there were not ten houses between Lambeth and where now is the west foot of Blackfriars' Bridge; but from that point a row of houses was continued to the borough. Where Christchurch now stands, was a theatre of some kind, called Paris Gardens. It is said that Ben Jonson was an actor on these boards. It seems to have been most frequented on Sunday, and to this profanation its fate has been attributed. Being filled with spectators in 1582, the scaffolding fell, when a number of persons were killed and many much injured. Below this was a large circular building for bear and bull baiting, which attracted great crowds, and where it has been said Queen Elizabeth frequently attended the spectacle. Southwark then extended but a short distance along the High Street, and there were small scattered houses from Tooley Street to Horsely-down.

During the reign of James, the streets were first paved with stones. The city was, however, visited by the plague in 1604, by which many of its inhabitants were carried off.

In the commencement of the reign of Charles I., the metropolis was once more visited by the plague; and though it was not of long duration, the deaths occasioned by it were estimated to amount to near 40,000 persons. In the civil wars of that unfortunate period, a majority of the corporation of London, and most of the lower class of citizens, took the side of the House of Commons; and the treasury of the city was found of great service to the party they espoused. As long as the king maintained an army, it was remarked by the writers of the day that no building in the city was carried on; but, after the battle of Leicester, the progress of erecting new houses proceeded as before.

Plague and great fire.

After the restoration of the monarchy, London began greatly to revive; but a serious check was given to its advancement, first by that dreadful visitation the plague, which first appeared in December 1664, and continued till January 1666. The greatest number of deaths were between May and October 1665, when the victims of this disease increased from 500 to 8000 in a week. The effect of this visitation, during its continuance, was to suspend all trade, to close the exchange and the courts of law, and to leave the houses, which had been rendered vacant by the demise of the occupiers, a prey to bands of thoughtless and desperate plunderers. The total number of deaths occasioned by this calamity has been estimated at 100,000, or nearly one-third of the whole population.

London.

A short period only intervened between this calamitous visitation and another, which seemed to be a dispensation of Providence, to cure one evil by another. On the 2d of September 1666, a fire broke out in a lane near London Bridge, then as now called Pudding Lane. It was on a Sunday, when the people were repairing to the churches. It spread with wonderful rapidity, being increased by a very high wind; and it is remarked by Vincent, that during the progress of the fire, the wind frequently changed its direction, so as to convey the inflammatory matter to parts in which, a few minutes before, no apprehension of danger had been entertained. The houses were mostly of wood, and much crowded together; water was scarce, and the atmosphere dry. In every direction the fire spread; and Evelyn, one of the most observant spectators, compares the whole spectacle to a sea of fire. It raged four days and nights, and in that time five-sixths of the whole city within the walls were reduced to ashes. In the destruction, the halls of the companies, the churches, and other public buildings, though of less inflammable substances than the dwellings, fell alike a sacrifice to the devouring element. At length the blowing up of some houses by gunpowder, depriving the fire of materials to feed upon, the progress was stopped near to St Bartholomew's Hospital, at a place called Pye Corner. The ruins covered a space upwards of a mile in length, and half a mile in breadth. It would have been difficult at that day, and is much more so at the present time, to estimate the pecuniary loss suffered by this visitation. It was calculated by some, but the grounds of the calculation are unknown, that the value of buildings and goods consumed amounted to ten or twelve millions sterling. A spirit of wisdom and generosity seemed to have been created by the magnitude of the suffering; and the government, as well as individuals, made wonderful exertions to administer relief. The tents in the Tower, and the sails from the shipping, were converted into temporary coverings for sheds to accommodate the inhabitants. The roads were almost choked with horses and waggons loaded with necessaries, and the boats and barges upon the river were occupied in the same employment. Measures were immediately adopted to rebuild the city, and a commission was appointed, of which Sir Christopher Wren was the most active member, for adjusting the boundaries of the property that had been covered with ashes, and for regulating the new streets that were to be built. Attention was not only directed to immediate necessities, but extended to other objects; such as rebuilding the public edifices which had been burned, of which St Paul's Cathedral was one.

By what means the number of labourers were collected, or from what funds the money to pay their wages was obtained, has been often the subject of very unsatisfactory inquiry; but it is certain that the city was rebuilt with a degree of rapidity which excited the astonishment of the age that witnessed it. The work was well conducted; for the greater part of the public and private buildings which now exist were erected at that period, and are still firm and strong after the lapse of 170 years. The city rose in about four years, more commodious than before; and, however the fact may be accounted for, since that period, it has never been visited by that tremendous disease the plague, whose recurrence before had been so frequent and so extensively fatal.

Reconstruction and growth of London.

From the time of this reconstruction, few events are to be noticed that affect London peculiarly. Almost all important occurrences belong rather to the history of England than to that of its metropolis. The revocation of the edict of Nantes in France brought to London many French Protestant families, who introduced the manufactory of silk, and peopled Spitalfields, and of others, who being ornamental jewellers and goldsmiths, were first established in Long Acre, Seven Dials, and Soho.

The continued growth of London in the reign of Queen Anne, induced the passing of a law in 1711 for constructing fifty new churches, for which a provision was made by a tax on all coals brought into the river Thames. The streets were first generally lighted at night. The several parishes were provided with fire-engines and buckets, and measures were instituted for watching the city. In the same reign, Clerkenwell, Old Street, the lower part of Shoreditch, Marlborough Street, Soho, Bedford Row, Red Lion Square, and a district north of Holborn, were added to the city.

In the reign of George I. some, but not great, additions were made to London, chiefly to the north of Oxford Street, about Marylebone, and Berkeley Square.

Although the increase of London proceeded, it was at a languid pace, compared with what has been more recently exhibited, throughout the whole reign of George II. New parishes were erected, viz. St George's, Bloomsbury; St Ann's, Limehouse; St Paul's, Deptford; and St Mathew's, Bethnal Green. The river Fleet was covered with an arch, and a market built upon it; Grosvenor Square was built, and also Westminster Bridge, with its appendage Great George Street. Roads were also formed in several directions, the chief of which was that from Paddington to Islington, surrounding the northern part of the city.

The accession of George III. was followed by the peace of Paris in the year 1763, and that event gave a fresh stimulus to improvement and extension. A new bridge was built at Blackfriars, with handsome streets leading to it, and a great number of new dwellings were erected on the Surrey side of the river. On the north-west side the parishes of Pancras and Marylebone were formed. It was at the same period that the excellent pavement forming the footpath for passengers was first laid down, and the kennels removed from the middle of the streets to the two sides of them. Most of the houses had large signs suspended across the street, which darkened them, and prevented the circulation of air. These were removed by law, and as they were used for distinguishing the several houses, the practice of fixing a number to each house was introduced. About the same time the names of the streets, lanes, and squares were ordered to be marked at each corner. During the early part of that reign, the complaints of the Spitalfields weavers, and the agitation created by Wilkes, with the war with America that succeeded these grumbling times, seem to have given a temporary check to extension, as only Somerset House and Manchester Square, with some parochial chapels in Marylebone, date their commencement in that series of years. The disgraceful riots of the year 1780, when, for a few days, a contemptible mob destroyed the prisons and several other buildings, may also have had a tendency to impede improvements, which continued to proceed with slow steps, even after the peace of 1783, till the accession of Mr Pitt to a firm seat at the head of the Ministry. Whether that minister was the cause of the improvements which followed, is not a question to be discussed here, but from this period the advance became more rapid, and has never slackened from that to the present day; but, on the contrary, has been constantly proceeding with accelerated force. The advance had its chief source in the power communicated by the rise of the funds in a short period from fifty to eighty-five; which supplied a spare capital for the construction of docks, by which the commerce of the city was rapidly augmented, and the ground near the water side covered with numerous and convenient structures.

The trade which enriched the eastern part of the metropolis extended its influence, and displayed its effects, in the western parts. Bedford Square, Russell Square, Brunswick Square, and the well-built streets contiguous to them, have their origin at the period we refer to, and became the habitations of persons, who, by property acquired in commerce, were enabled to spend the latter portion of each day in more elegant quarters than the city offered; though, at that time, the handsome square of Finsbury had been formed, with many good streets in its vicinity.

The accession of George IV. to the regency in 1812, followed by those glorious victories which led to peace two years afterwards, must be viewed as an era from which to date the commencement of that rapid advance in extent, in elegance of design, and in excellence of workmanship which London now displays, and which is rapidly proceeding.

Population.

In the description of this vast city the first object is the population, its numbers, and gradual augmentation. Like the rest of England, the number of inhabitants in London was a subject of controversy, till the first census of the whole kingdom taken in the year 1801, was produced to the public by the indefatigable and accurate labours of Mr Rickman, under the sanction of an act of Parliament. As the facts ascertained by him at that period have been confirmed by the three subsequent decennial census of 1811, 1821, and 1831, no doubt can be entertained of their complete accuracy.

Mr Rickman in a kind of summary of population in the limits he assumes, and very properly, as those of the metropolis, makes it in the year 1700 to have been 674,000, in the year 1801 to amount to 1,031,500, in 1811 to 1,220,200, in 1821 to 1,481,500, and in 1831 to 1,776,556. As by the successive enumerations, it is clear that the inhabitants have gone on increasing at the rate of twenty per cent. in ten years (and there is no reason to suppose it has proceeded at a slower rate in the last four years), we may add eight per cent. to the population of 1831, and assume that at the present time (April 1835), it amounts to 1,918,680.

The limits to which this enumeration refers, is to all those parishes the churches of which are situated within eight English miles in a straight line from St Paul's, adding a twenty-fifth part in each instance as a moderate allowance for the great number of British seamen belonging to the registered shipping at anchor in the Thames, for soldiers quartered in the Tower and in other barracks, or for the transitory population continually arriving and departing so irregularly as to escape all enumeration.

In giving the population of the metropolis, we shall state that of the *city within the walls* in a condensed form, not enumerating each parish, of which some have not 100 inhabitants; but in the *city without the walls*, where the parishes are more populous, in Westminster, and in the out-parishes, we shall name each, with their population at every decennial census.

The city within the walls contains 97 parishes, with a church to each; and the population amounted, in 1801, to 75,377; in 1821, 56,174; in 1831, to 55,778.

The following are the parishes without the walls.

	1801.	1811.	1821.	1831.
St Andrew's, Holborn, with Barnard's Inn,	5,548	5,741	6,234	5,570
St Bartholomew the Great,	2,645	2,769	2,931	2,923
St Bartholomew the Less,	951	843	823	863
St Botolph without Aldersgate,	4,161	4,135	4,003	3,994
St Botolph, Aldgate,	8,686	8,297	9,067	9,615
St Botolph without Bishopsgate,	10,314	9,184	10,140	10,025
St Bride's or Bridget's,	7,078	7,003	7,288	6,860
Bridewell Hospital, with extra parochial precinct,	453	459	444	360
St Dunstan in the West,	3,021	3,239	3,549	3,443
St Giles' without Cripplegate,	11,446	11,704	13,038	13,134
St Sepulchre without Newgate,	8,092	8,724	8,271	7,710
Trinity in the Minories,	644	602	680	508
White Friars' precinct,	783	926	1,247	1,302
	64,486	64,228	68,395	66,815

City of Westminster, in ten parishes.

	1801.	1811.	1821.	1831.
St Anne, Soho,	11,637	12,288	15,215	15,600
St Clement's Danes,	8,717	9,796	10,753	11,578
St George's, Hanover Square,	38,440	41,687	46,384	58,209
St James's,	34,462	34,093	33,819	37,053
St John's,	8,375	10,615	16,835	22,648
St Margaret's,	17,508	18,680	22,387	25,314
St Martin's in the Fields,	25,752	26,585	28,252	23,970
St Mary le Strand,	1,704	1,578	1,784	2,052
Duchy Lancaster,	474	443	489	410
St Paul's, Covent-Garden,	4,922	5,304	5,834	5,203
Close of the Collegiate Church of St Peter,		175	181	185
Savoy precinct St John Baptist,	320	287	222	431
Verge of the palaces of St James's and of Whitehall,	1,685	182	641	238
	153,996	161,713	182,796	202,891

Parishes in Southwark, described by the bills of mortality as parts of the city without the walls.

	1801.	1811.	1821.	1831.
St George's,	22,293	27,967	36,368	39,769
St John's,	8,892	8,370	9,163	9,871
St Olave,	7,846	7,917	8,420	8,694
St Saviour's,	15,596	15,349	16,808	18,006
St Thomas's,	2,078	1,586	1,807	1,456
	56,705	61,189	72,566	77,796

Parishes described in the bills of mortality as " Out parishes in Middlesex and Surrey."

	1801.	1811.	1821.	1831.
Christchurch, Surrey,	9,933	11,050	13,339	13,705
Christchurch, Spitalfields,	15,091	16,200	18,650	17,949
St Dunstan's at Stepney,	25,260	35,199	49,163	67,872
St George's in Bloomsbury, united with St Giles' in the Fields,	36,502	48,536	51,793	52,907
St George's in the East	21,170	26,917	32,528	38,505
Carry over,	107,956	137,902	165,473	190,938

	1801.	1811.	1821.	1831.
Brought forward,	107,956	137,902	165,473	190,938
St George's by Queen Square,				
St Giles' in the Fields,				
St James's, Clerkenwell,	23,396	30,537	39,105	47,634
St John's, Clerkenwell,				
St John's, Hackney,	12,730	16,771	22,494	31,047
St John's, Wapping,	5,889	3,313	3,078	3,564
St Katherine's, Tower,	2,652	2,706	2,624	72
St Leonard's, Shoreditch,	34,766	43,930	52,966	68,564
St Luke's, Middlesex,	26,881	32,545	40,876	46,642
St Mary's, Islington,	10,212	15,065	22,417	37,316
St Mary's, Lambeth,	27,939	41,644	57,638	87,856
St Mary's, Bermondsey,	17,169	19,530	25,635	29,741
St Mary's, Newington,	14,847	23,853	33,047	44,526
St Mary's, Rotherhithe,	10,296	12,114	12,523	12,875
St Mary's, Whitechapel,	23,666	27,587	29,407	30,733
St Paul's, Shadwell,	8,828	9,855	9,557	9,544
	337,227	417,352	516,440	641,052

The following parishes are in contact with the metropolis, and are necessarily the portions in which its greatest extension has of late years been made, and in which the future greatest increase of houses and inhabitants must also take place.

	1801.	1811.	1821.	1831.
Chelsea,	11,604	18,262	26,860	32,371
Kensington,	8,556	10,886	14,428	20,902
Marylebone,	63,982	75,624	96,040	122,206
Paddington,	1,881	4,609	6,476	14,540
Pancras,	31,779	46,333	71,838	103,548
	117,802	155,714	215,642	293,567

Besides the portions formerly called London, the extension of its limits upon every side has caused junctions between the metropolis and many large villages, which are now scarcely to be distinguished from, and in fact form suburbs to it, and rapidly increase with it. They are now as much a part of London as Paddington or Marylebone, because the people who inhabit the houses have their chief occupations in the metropolis, and are thence supplied with most of the necessaries they consume. The calculation before noticed was made by Mr Rickman, to shew the contrast between the population of London and that of Paris, and comprehended a circle of eight miles around St Paul's; but since the publication of his reports, the law of 1834 has extended the criminal circuit of London somewhat farther, and included in it not only the villages in Middlesex whose prisoners were always tried at the Sessions at the Old Bailey, but has brought within the limits of that court, towns and villages in Essex, Surrey, and Kent. The places forming, in this view, a part of London, besides those included in the population already stated, are these: in Middlesex, Tottenham, Edmonton, Hornsey, Highgate, Hampstead, Hayes, Hendon, Wilsden, Brentford, Acton, Cheswick, Isleworth and Fulham, with Hammersmith; in Surrey, Battersea, Bermondsey, Camberwell, Clapham, Streatham, Barnes, Putney, Tooting, Wandsworth, Merton, Mortlake, Kew, Wimbledon, and Richmond; in Kent, Eltham, Charlton, Lee, Lewesham, Greenwich, Woolwich, Plumstead, and Deptford; and in the county of Essex, Barking, East Ham, West Ham, Ilford, Low Layton, Walthamstow, Wanstead, Chingford, and Woodford.

Not to occupy too much space, the growth of the population of these places must be omitted; but the number of inhabitants at the census of 1831 is extracted, and stands thus: In the places within the county of Middlesex, as above mentioned, 70,458; in the county of Surrey, 124,185; in the county of Kent, 79,971; and in Essex, 33,769; being together 308,389.

The whole population of the metropolis in May 1831 may thus be enumerated:—

City within the walls,	55,778
City without the walls,	66,815
City of Westminster,	202,891
Borough of Southwark,	77,796
Out-parishes in the bills of mortality,	641,052
Parishes not in the bills of mortality,	293,567
Other places within the new judicial circle,	308,389
	1,646,288

As the limits here assigned to the metropolis are different from those assumed by Mr Rickman, the result of the numbers necessarily varies without any incorrectness in either representation, each of which is taken from the same ascertained facts. Mr Rickman, as has been before remarked, has very judiciously added to the number of persons, as collected from house to house in the metropolis, one twenty-fifth part for seamen, military, and temporary residents; which, considering the great number on board the ships, seems not too much. Following the same rule, and adding that proportion to the number before stated, we conclude that the sum total of the population in 1831 was 1,704,830; and, allowing for the same rate of augmentation of two per cent. per annum, similar to what has appeared by the accounts of former periods, we arrive at a conclusion approximating as nearly to accuracy as the nature of the matter will admit, that, in June 1835, the metropolis as here defined contained 1,838,490 souls.

Situation of London.

London was founded in a situation peculiarly favourable for a large city. It stands on the banks of a fresh-water river, but yet is operated upon by the tides. The natural soil is composed of gravel and clay, with slight mixtures of loam and clay, a soil easy to be made productive by addition of that animal and vegetable matter which are exuviæ of large towns. In every part there are abundant springs of pure water. The valley of the Thames has an immediate gradual ascent on the north side; and on the south side the range of hills is not more than two miles distant, and the intervening flat land has by embankments been well secured against inundations. The air is temperate and rather dry than moist, and the health of the inhabitants has gradually but rapidly improved from the beginning of the last century, when the deaths were annually one in twenty of the whole population, whereas at present they are about one in forty.

Thames.

The existence, the growth, and the prosperity of London have all been so indebted to its situation on the river Thames, that any description of that city would be imperfect which did not dedicate a portion of it to what relates to that noble stream.

The source of the Thames is just within the borders of Gloucestershire, a little to the south-west of Cirencester; and after crossing a small angle of Wiltshire, it again enters that county, and proceeds to Lechlade. At that place it is brought into connexion with the river Severn by means of a navigable canal, which passes through a tunnel under the park of Lord Bathurst, and then proceeds by Stroud to the river which passes Shrewsbury, Worcester, Gloucester, and Bristol. This was the first communication which was formed between the two greatest of the English rivers. Bold and public spirited as this attempt was, those who have expended their money and their attention on it have reason to regret the inadequate compensation which they have received or are likely to receive.

The Thames becomes first navigable at Lechlade, and by means of locks carries long barges of about seventy tons burden; but the navigation is long and expensive. In summer, when the water is low, it is necessary to pen it up at the locks till a sufficient body is accumulated. When they are opened, the rush carries them down till they get aground, when they must wait for the next flash, as it is locally called, to carry them forward. In winter it often happens that the water is so swollen as not to admit the barges, whose cargo is piled up high, to pass under the arches of the bridges. Though the barges descend by the current, they must be drawn upwards by horses against the stream, which is very expensive, as, after heavy rains, it is not unusual to see fifteen or sixteen horses drawing a single barge, and with the greater difficulty from the towing paths being at such times covered with water. The Thames proceeds along its rich, but in places contracted, valley, till it arrives at Oxford, where it is joined by the Isis, a short but at times copious stream, rising near Iylesbury in Buckinghamshire. From additional quantity of water the barges that navigate from Oxford to London are of a greater burden than those which are used on the more western portion of the stream.

At Reading the river Kennet empties its water into the Thames. That river is navigable upwards to Newbury, whence a canal connects it with the Avon, which passes to Bath and Bristol; and thus another line of communication is formed between the two great streams the Thames and Severn. Near Stains the river Coln adds its water to that of the now great stream. A few miles lower the Wey joins it, and by a canal from that stream to Basingstoke, a water intercourse is formed with Winchester and Southampton. At Brentford a communication by a cut is made into the Grand Junction Canal; and the Thames proceeds to London with no addition to its water except from the river Wandle on the Surrey side, and some small brooks on both sides. The effect of the tide is felt as high up as Kingston, and sometimes even at Teddington. The rise of the tide just below London Bridge is eighteen feet, by which vessels of three hundred and fifty tons drawing sixteen feet water can approach to the Custom-house. At Deptford the rise is more than twenty feet, by which the largest India ship drawing twenty-three feet water may come to that place. The river continues fresh as low as Woolwich, and even there it is only brackish at high-water in spring-tides. The river above London flows generally over a gravelly or clayey bottom, which gives growth to abundance of weeds, that afford shelter to vast multitudes of fish, and protects them for the illegal fisherman more than the care of the water-bailiff. The length of the course of the river, from the time it becomes navigable at Lechlade, till it reaches London, is 138 miles. As the corporation of the city are the conservators of the river, they appoint a navigation committee, who have the superintendence of the towing-paths, the bridges, the water-courses, and whatever relates to the river, as high as a stone marking the city boundaries a little above the bridge at Staines. Above that place the supervision is divided between the city and a body corporate, which is chiefly composed of the land-owners on both sides of the river.

The conservation of the river Thames below London is also in some measure under the government of the corporation of the city, and extends up the Medway to Rochester; but the corporation of the Elder Brethren of the Trinity House have a concurrent jurisdiction. The city has the protection of the fishery, but the soil of the river to the main sea is vested in the Trinity House, for the benefit of poor and decayed seamen, their wives, widows and orphans, and no ballast can be raised for any ship without its authority, under very heavy penalties. The appointment and control of pilots, the erection and repairing of marks on the land, the placing and keeping in order the buoys which indicate the channels, and the establishment of floating lights, are under the superintendence of the Trinity House. As there are numerous shoals in the river, and some of them often shift their position, a great deal of vigilance is required, as well as practical nautical knowledge, to perform these important duties; and the legislature has placed the shipping of the port of London under the direction of harbour-masters nominated by the corporation and approved by the Trinity House, who direct the mooring of all vessels excepting within 200 yards of the docks, which space is under the control of the dock-masters. In the river Thames, the time of the tides flowing, and the perpendicular height to which it reaches at the full and the change of the moon, are as follow: At London, at $11\frac{3}{4}$, it rises 18 feet; at Woolwich it is high water at $11\frac{1}{4}$, at Purfleet at $1\frac{3}{4}$, at Gravesend at $1\frac{1}{2}$, at Holy Haven at $12\frac{3}{4}$, at the Nore $12\frac{1}{2}$; the rise at Purfleet is 17 feet, at Holy Haven 15, and at the Nore 14; but allowance must be made for the wind, which when high greatly affects the tide.

The tide at the mouth of the Thames is thus full more than two hours before it is high water at London Bridge, and after it flows there, it rises in height upwards for half an hour, in the middle of the river, although the water may have fallen a foot in height, having an eddy current on one or both sides the stream. In like manner, it rises one foot in height before the flood appears to run up.

Navigation of the river.

Owing to the numerous, and sometimes opposite, directions which the river takes, the change of its currents according to the state of the tide, and the various shoals in many parts, the navigation is intricate and difficult, and the river-pilots are a distinct class of men from the sea-pilots; the former conducting vessels to Gravesend, and the latter taking charge of them to the Downs, or even to Portsmouth, if they are bound to that place.

Before the introduction of steam-vessels, and the application of them to the purpose of towing ships, it frequently happened to large loaded vessels ready for sea, whilst an easterly wind blew which would be favourable if they were at sea, that they could not safely descend the river to take advantage of it. It was too dangerous for such large vessels to attempt to drop down with the ebb tide, and impossible to turn to windward against the flood tide; but now steamers can take them in tow and carry them without risk to the part where they can avail themselves of the propitious breeze.

As the mouth of the Thames, like that of other great rivers, is filled with sand brought down by the constant current of the water, through which banks the water makes its way by channels of greater or less capacity, it is necessary that such channels should be clearly pointed out either by buoys or lights. At the mouth of the Thames, these indications of the channels are numerous, accurately placed, and so distinguished that each can be easily known. The buoys are chiefly to be distinguished by their colour, with due regard to their position or bearing from some object upon the land. They are securely moored, but turn with the tide. Those upon the several channels are well known to the pilots, and their enumeration here would be of no use, as no vessels attempt the passage in or out without a pilot on board. The lights are fewer, and deserve notice. At the Nore, where the Thames is about nine miles from shore to shore, one of the great channels through the sandbanks begins; a light vessel is placed in the room of a former one which was removed in 1825. The old vessel had two lights, but the present has only one, though of great brilliancy. At the sunk sand there is a floating light, which is an excellent guide for the King's Channel; this is only four miles from Harwich lighthouses, for there are two of different heights, which must be kept in a line in going through the channel to that place. There are two towers with a light in each at the same height, but one of these towers was in 1818 raised forty feet above its lightroom, in order to serve as a day-mark.

On the north passage through the sands, there is a great shoal called the Galloper, extending about four miles in length and being half a mile wide, with only six or seven feet water at low tide. Ever since the year 1804, a vessel has been moored at the south-west end of the sand, in which two lights are exhibited horizontally, from sunset to sunrise. This may be readily distinguished from the Sunk and the Goodwin lights, as the former exhibits but one and the latter three lights.

There is a lofty lighthouse on the north Foreland, which is an ancient erection of great importance to ships coming in from sea, by which a ledge of rocks which stretch two-thirds of a mile northward from that point, may be avoided. On the pier-head of Ramsgate a light is placed, the principal object of which is to serve as a guide to the harbour. As the lights from the windows of the town were liable to be taken for this, shades of red glass have been affixed, so as to produce a clear red light easily distinguishable.

The floating light of the Goodwin is intended chiefly for the benefit of vessels arriving from the northward, which, if possible, keep to the eastward of it. In order to distinguish this from the lights on the two Forelands, three distinct lights are exhibited from the vessel, which is with one mast and a yard crossing it securely moored. The middle of these three lights is considerably higher than those at the two extremes, thus forming an erect triangle not easily mistaken. In foggy or hazy weather, a bell is kept constantly ringing on board, to warn ships that they are near the north end of the sand. On board this vessel, thus kept continually in motion, the small crew is frequently for a long time completely cut off from all intercourse with the shore. On the south Foreland there are one or two lighthouses, but these scarcely belong to the mouth of the Thames, being placed chiefly with a view to prevent vessels from running on the Goodwin sands.

Docks.

Complaints, as the commerce of London increased, became very frequent, of the crowded state of the river, of the delay and difficulty of procuring good berths for ships, and of the want of accommodation for discharging cargoes, owing to the scarcity or the distance of commodious warehouses. These complaints called the attention of the merchants and ship-owners, and at length that of the government, to the subject. There were many difficulties to be surmounted, arising from the vested rights of the corporation, and of private individuals who had property in the mooring chains, in the legal quays, the suffrance wharfs, the upland warehouses, and in lighters or other craft, all of which would be injured by the construction of docks. Mr Pitt, then minister, applied all the powers of his mind to the subject in the committee of the House of Commons; and at length, after seven years' agitation, and with ample compensation to the sufferers, the law was put in force by the commencement of the West India Docks, in February 1800, and by their being opened for the reception of ships in August 1802.

West India Docks.

These, the first establishment of the kind in London, were formed in the gorge of an isthmus called the Isle of Dogs, on the Middlesex side of the river. They comprised at first an import and an export dock, each communicating with one basin of five or six acres in extent, with the main river at Blackwall, and another of two acres at the other end near Limehouse; and parallel to these was constructed the city canal, which having been rendered useless by the application of steam-vessels to tow ships, has been recently also formed into a dock, and contains nineteen acres, now used as a depôt for bonded timber.

The export dock, where eastward-bound ships are loaded, is the smaller of the two, being about twenty-five acres in extent. The import dock is of the same length, but thirty feet wider, and occupies thirty acres of ground. The locks by which admission to both is gained, are forty-five feet wide, and consequently admit vessels of 1200 tons burden. At the highest spring-tides the water is twenty-four feet deep; and there is within the docks sufficient space for 600 vessels of from 250 to 600 tons burden. A great benefit has been gained, both by the revenue and the traders, by the separation of the import from the export dock. They are parallel to each other, but are divided by stacks of warehouses, the chief commodities in which are rum, brandy, and other spiritous liquors. There are sheds on the side of the export dock, which afford shelter for goods sent for exportation. The chief warehouses for import goods are on the quays which bound that inclosure. They are admirably contrived for the reception, preservation, and delivery of goods, and are capable of storing 170,000 hhds. of sugar, besides coffee and other tropical productions.

The whole space occupied by these docks and warehouses extends over 295 acres. It is inclosed on every side; all the buildings are fire-proof; and the premises are well guarded by watchmen, so that the system of pilfering, formerly practised to a great extent on the river, is completely abolished. The carts or waggons which convey goods to town are loaded from the backs of the warehouses, without entering the dock-gates. The capital of the company which built and now superintend the docks is L.1,380,000, raised by subscriptions at different times. The proprietors were limited to ten per cent. interest, and if the income amounted to more, the tolls and storage were to be reduced in price. This establishment had the monopoly of the West India trade during the first twenty years after their construction. At that time they accumulated a sum which in 1819 induced them to lower their rates. But of late, from the competition of other companies, though their profits did not reach ten per cent., they have been induced to diminish the rates. The dividend now scarcely exceeds five per cent.

The nearest end of these docks is at Limehouse, three miles from the Royal Exchange, and the other end at Blackwall is half a mile farther. The expense of cartage, though the road is excellently paved, is therefore greater than from the docks which have been subsequently constructed, and it is doubtful if the benefit to the shipping by not proceeding so high up the river is an adequate compensation.

Some admirable contrivances have been recently adopted, by which the great body of water in the docks is kept always sweet, and by which the constant deposit of mud from the water of the river is carried away gradually.

London Docks.

The docks which next followed the West India in their construction are the London Docks, situated between Ratcliff Highway and the Thames. They were begun in June 1802, and opened for the admission of vessels in January 1805. They were originally planned chiefly to receive ships and their cargoes loaded with tobacco, wine, brandy, and rice. They consist of two docks of unequal extent; the western covering a space of twenty acres, and the eastern of about seven acres. The latter is entered through a small basin from Shadwell, and the former has two through their basins, the one between Wapping Old Stairs and Bell Dock, and the other at the Hermitage. The whole can commodiously receive 500 vessels of from 200 to 800 tons burden. The warehouses are very magnificent; the most extraordinary is that for bonded tobacco. The roof and pillars which support it are of iron, and the whole building covers five acres of land, and is capable of containing 24,000 hogsheads of that commodity. There is another warehouse for tobacco, but of smaller dimensions. The vaults under these and the other warehouses are in extent more than eighteen acres, and have space to store 66,000 pipes of wine or spirits. This company, like that of the West India Docks, had a monopoly for twenty-one years, which expired in 1826; by this all vessels loaded with wine, brandy, tobacco, and rice were bound to discharge their cargoes on their premises.

The company is governed by a directory, of whom the Lord Mayor and a certain number of aldermen form part. Their capital was L. 3,328,000; and besides that, as they had to pay for 1300 houses, which were taken down to make room for the operations, they were compelled to borrow L. 700,000. This great expenditure, and the rivalry of other similar associations, which have reduced the rates of tolls and storage, have of late only enabled the company to pay two and a half per cent. interest to the proprietors.

The regulations to prevent fire and pilfering are as effectual in those as in the West India Docks. The whole consists of seventy-one acres, and is walled, and the hours for admission and for working are the same as in the other docks.

East India Docks.

The East India Docks followed those of London. The commencement of the work took place in 1803, and its completion in 1806. They are at Blackwall, and designed for the trade of the East India Company. They consist of an import basin of eighteen acres, and of an export basin of about nine acres, with an entrance basin of $2\frac{3}{4}$ acres. As they were constructed to receive ships of great burden, the length of the entrance lock is 210, and the depths of the gates forty-eight feet, and there is never less than twenty-three feet of water. The extent of warehouse-room is small, as most of the commodities unloaded here are carried immediately to the Company's warehouses in the different parts of London. The tea and the more valuable goods are conveyed in covered waggons, secured by locks, along the Commercial Road, which has been constructed to communicate with these and the other docks. The capital of the Company is L. 500,000, paying a dividend of four per cent. The directors of the Company have the chief management, and the ships are loaded and discharged by their servants, not by the crews; and the regulations to prevent fire and plunder are of the strictest kind.

St Katharine's Docks.

St Katharine's Docks, the last that have been constructed, are situated between the London Docks and the Tower. Though a great work, it was executed within a year and a half, and first opened in October 1828. The whole extent of the property is twenty-four acres, of which nearly one-half is included in the two docks, communicating by a basin between them. The entrance is near Irongate, where the lock from the river is 180 feet long, and 45 feet broad, and is so constructed as to admit ships of 200 tons burden to pass out three hours before high water, so as to enable them to reach Blackwall before the ebb of the tide begins. Ships of 800 tons burden can be conveniently received into these docks, as the water at the entrance is deeper than at any of the other docks, and they can enter or depart by night as well as by day; and vessels drawing eighteen feet water may be afloat at a buoy opposite the gates at low water. The two divisions are estimated to be capable of receiving annually about 1400 merchant vessels. The warehouses are very large and commodious, and, being partly erected upon pillars close to the water, goods are craned up to them direct from the hold of the discharging vessel, at a diminished expense of time and labour, whilst the space is also thereby economised. The whole work has been executed with great skill, taste, and judgment, and its situation being within a quarter of an hour's walk from the Royal Exchange and the Custom House, is a very great accommodation.

The expense of this concern has been very great for its extent, arising chiefly from the number of houses which required to be purchased and pulled down, to make way for the excavation. The capital originally raised was L. 1,350,000, since which L. 800,000 have been borrowed on the security of the tolls, for the completion of the works, and the purchase of land, possessing river frontage, from the Tower to the corner of Lower East Smithfield. This, which cost more than L. 100,000, has been recently made applicable to the erection of a wharf, at which steam-vessels can take in or land passengers without the inconvenience of embarking by means of wherries. The regulations of this dock and the charges are similar to those of the other.

Commercial Docks.

On the right bank of the Thames, extending along the side of the river at Limehouse, reaching from Dog and Duck Stairs to near Cuckold's Point, and terminating nearly opposite to the entrance of the West India Docks, are the Commercial Docks, and parallel to it the Surrey Canal. The Docks are of great extent, inclosing within walls forty-nine acres, of which thirty-eight are water. They were designed to receive vessels loaded with timber, corn, and other commodities which are more bulky than costly. The warehouses are neither extensive nor commodious, and their establishments not so constructed as to entitle them to become bonding warehouses for many kinds of goods. They are entered by a basin near Dog-and-Duck Stairs, which is sometimes called the East-Country Docks, and the main body of the water within is divided into three unequal parts. The Surrey Canal consists of an inner and outer dock at its entrance, in which ships are received; but at present it is chiefly used for the reception of vessels offered for sale. There is a communication by it with the Croydon Canal. As the ships employed in foreign or colonial commerce generally enter these docks to discharge or take in their cargoes, there is room left in the river Thames for the coasting trade, including that with Ireland and Scotland. Of these the greater portion are such as are loaded with coal from the northern counties, which are allowed to anchor in what is called the Pool, a part of the river extending from the Custom House to the entrance of the Regent's Canal, near Limehouse. In this part, 210 vessels may anchor at one time; but the average number of them does not exceed 180, though about 7000 ship-loads of coals are annually discharged.

As the Regent's Canal terminates near the London and the West India Docks, it may be appropriately noticed in this place. The chief object of this work was to save the expense of cartage through London of those articles brought by sea and afterwards forwarded for consumption to the distant parts of the metropolis in the north-west division, and to communicate there with the Grand Junction Canal. It therefore passes in a circular course round London from Paddington on the west to Limehouse on the east. It passes by a tunnel under Maida Hill to the Regent's Park, and from thence to Islington, under the street of which it is carried through a tunnel about three quarters of a mile in length, where there is a large basin. It then proceeds to Hoxton, Hackney, and Limehouse. It is nine miles in length, and has twelve locks so admirably contrived, and so large, that barges eighty-three feet long and fourteen wide can pass and not occupy more than three and a half minutes in passing. It has much trade in coals, and some in conveying goods from London to be sent to the northern parts of the kingdom. It has been found a very expensive work, and, whatever may hereafter be its increase of trade, does not at present pay more than fifteen shillings interest on 21,400 shares of L.100 each.

It would serve to give some idea of the trade of London in general, and the utility of the docks as subservient to it, if our limits would allow of an enumeration of the names and the quantities of all the commodities under the king's locks in the several bonding warehouses of the port. We have only room to notice some of the most prominent.

Account of some articles in bond in London the 5th January 1833.

In the trade with Russia, somewhat more than nine-tenths is carried on by means of British vessels. In that with Sweden, Norway, and Denmark, the case is the reverse, and five-sixths is carried on in vessels of those countries. In that with Prussia, whose ships are of a larger size upon the average than those of Great Britain that frequent the Baltic, their tonnage in London is about double of our own. The commerce with the other states of Germany, employs double as much tonnage in British as in foreign ships, and the same proportion is found in the trade with the Netherlands. In the intercourse between London and France, the number of British vessels employed is to that of foreign as seven to six; but as the average of British vessels is somewhat larger, the proportion of tonnage is as eight to five in favour of our own shipping. The vessels which bring cargoes to the metropolis from Portugal, the Azores, and Madeira, from Spain and the Canaries, and from the Italian states, are almost wholly British, as the number and tonnage of the foreign ships that arrive, do not amount to more than two and a half per cent.

The commerce with the Ionian Islands, with Turkey, and Continental Greece, with the Morea and the Greek Islands, with Egypt, with Tripoli, Barbary, and Morocco, with the foreign territories in Africa and in Asia, and with China, is wholly in British-owned vessels. In the London trade with the United States of America, the foreign vessels, mostly those of the States, are to the British vessels in the proportion of nearly four to one. The commerce with the West Indies, and with the continental colonies in America, is almost wholly conducted in British ships, as out of 500 sail of vessels that arrived in the Thames with cargoes from those parts there were only forty, and those of small size belonging to foreigners.

The whole of the commerce of Great Britain, with the colonies of North and South America, with the islands in the West Indies, with the settlements on the coast of Africa, and with the East India Company's extensive territories, is carried on by British ships alone; but it is not easy to estimate what proportion of it employs ships belonging to London. In fact, those which at one period of the year are employed in one branch of commerce, are often employed in another in a different part of the same or of a succeeding year. Many, too, of the British ships which arrive at or depart from London, are owned by persons resident in other, especially the northern, parts of the kingdom.

In the absence of any recent account, it may be as near an approximation to accuracy as can be obtained, if the number and tonnage of the vessels belonging to the port of London be assumed to bear the same proportion to the number of those that belong to the whole of the kingdom, as is exhibited by the net amount of the produce of the duty of customs. In this view the year 1833 may be taken, when the whole sum drawn to the revenue from the three kingdoms was L.18,575,182 : 15 : 9, and the sum drawn from the port of London was L.7,662,521. In that year the tonnage of all the ships in the United Kingdom, and of our possessions in Europe, was 2,271,301. Of this a vast part were occupied in the coasting trade, and the vessels so employed were, in most cases, owned by persons in the out-ports. The fisheries, whether for herrings, ling, or pilchards, on our own coasts, as well as those for whales in the northern ocean, or for cod on the banks of Newfoundland, are mostly conducted in vessels also owned at the out-ports; and though the southern whale-fishery is chiefly carried on from London, the tonnage it employs is insignificant when put in comparison with that of the other branches here noticed. If a deduction be made for the tonnage of the coasting vessels, including the colliers, and of the fishermen, to the amount of 650,000 tons, from the 2,271,300 tons which appear on the register, there will remain about 1,620,000; and, in conformity with the view of reckoning the tonnage by the custom's revenue, that of London being near two-fifths of the whole kingdom, so, if the shipping of London be two-fifths of that of the whole tonnage on the register, it will be about 650,000, which cannot be very far from the truth.

It is not easy, within a moderate compass, to give even a sketch of the foreign commerce of London. It would be an epitome of that of the whole world. The British capital is the emporium to which are brought the products of all soils, and all climates, whether such as are spontaneously produced, or such as have been gradually created by ages of observation and application. It has in store ready for distant commerce, or for domestic use, whatever the ingenuity and industry of man in any part of the globe can spare to exchange for what his own country, or climate, or skill, cannot yield him. We could, therefore, do little more here than point out, as we have done, the foreign countries with which the chief intercourse is maintained, and the proportions of it, as far as they can be indicated by the number and size of the vessels that convey their commodities.

An Account of the Number of Vessels, and their aggregate Tonnage, that have entered the Port of London from all foreign countries in each year from 1820 *to* 1834.

Years.	British.		Foreign.

Customs.

On account of the fire at the Custom-house in 1814, which destroyed the accounts of many years before 1800, it is not easy to ascertain what was the amount of duty collected by the commissioners of the customs prior to that date; and some of the accounts of subsequent years having also been then destroyed, the series is very much broken till 1825. The following is all that can now be obtained.

Statement of the Gross and Net Receipt of the Customs-duty at the Port of London, as far as the same can be made up from existing documents.

Year.	Gross Receipt.	Net Receipt.

The comparative commercial importance of London may be shewn by contrasting the amount of the duty of customs collected in it, with that collected at the greatest of the maritime towns within the three kingdoms.

Net Amount of Duty collected at the Customs in the year 1833, as transmitted to the Treasurer.

One of the chief sources of occupation for shipping is the conveyance of coals to London. They are chiefly brought from the north-eastern side of the kingdom, and sold on their arrival by the cargo at an appropriate building in Thames Street, called the Coal Exchange. The great dealers sell the coals by barge-loads to the lightermen, wharfingers, and other retailers; and when they are discharged from the vessels that bring them to the Pool, they are usually kept in coal barges at the several wharfs, ready to supply the consumers. A great benefit has lately been conferred on the public by the change in the mode of selling coals, substituting weight instead of measure, or the ton for the chaldron. As coals measure more when much broken, it was the interest of the dealers to break the large lumps; but now that they are sold by weight, they have no inducement to break them, and they are delivered more lumpy. Each waggon or cart that brings coal to the consumer, is bound to bring appropriate weights and scales, and to weigh such part, if the buyer should require it. By this some of the tricks formerly played in this trade are prevented. The ton of coals is sold, including cartage, which varies according to the distance from the water side, and the porterage, according to the quality, from 24s. to 30s. The chaldron, which was before the law 1st and 2d Will. IV. cap. 67, the legal measure, weighs one ton five hundreds and a half.

The quantity imported in each of the ten last years has been as follows:—

	Tons.

The institutions of the city of London, which have grown up with and out of its commerce, are highly appropriate, by their localities, their arrangements, and their regulations, for conducting business. The first object of importance to every ship, on its arrival in port, is the *Custom-house.* This noble building has been erected on the site, but with much enlargement, of a similar building which was destroyed by fire in 1814, as the preceding one had been by a similar calamity in 1718. A considerable extension, and many alterations in the building, had been commenced before the last fire occurred, but that accident induced the erection of an entirely new edifice, which was opened for public business in May 1817.

Custom-house

The custom-house stands in Lower Thames Street, but its principal front is towards the river, with a broad wharf, having noble stairs at each end, by which to descend to the water, whence wherries are constantly plying for passengers, who can embark or land at them with their baggage, but where no goods are allowed to impede the way. The length of the front is 480 feet, and it is 60 feet in depth. On the view from the river, the front exhibits itself best, with three porticos, each composed of six pillars of the Ionic order, the centre one of which projects somewhat more forward than the others, and is more elevated from the ground by standing on arches. On the top of it is a balustrade, with a clock in the centre.

The arrangements of the interior are, however, most to be admired. The long room, where most of the public business is transacted, is a noble apartment 186 feet in length, and 60 in breadth, of an appropriate height, with desks on each side for the several officers, and the centre left open for such of the public as have business there. The other parts of the edifice are distributed with great judgment into apartments adapted for the several branches of the office, in such a way that between six and seven hundred officers, and more than a thousand tidewaiters and messengers are enabled to work with regularity and dispatch, thus forming a most pleasing contrast to the confusion, difficulty, and delay which formerly prevailed.

An accident happened to this building in 1825, when a part of the long room fell in; it was found that the foundation had been insecurely constructed, upon which the centre was taken down and rebuilt as it now appears, under the direction of Mr Smirke.

The improvements on the building and its arrangements, great as they are, are trifling, when compared with the vast reform in the whole system which took place by the law of 1812 (act 51st Geo. III. cap. 7.), and by other salutary regulations. Before that time, the highest offices were held by patent, and the duties performed by deputies, and both were paid by fees. These were abolished, and all are now paid by salaries. Patronage in promotion has been relinquished, and the road opened to the advancement of the most meritorious officers; and, by an order of the Treasury, when the Duke of Wellington was at its head in February 1830, the salaries of the commissioners and other officers were prospectively reduced; whilst directions were given to revise the whole establishment, with a view to every possible reduction.

Bank of England.

The *Bank of England* is one of the most prominent objects within the city, not so much from the structure, though that is magnificent, as from the great influence its creation and progress have had on the state of society in general, as well as on the commercial intercourse which it has facilitated between different individuals at home, and between distant countries with this kingdom, and with each other.

The company was first founded in the reign of King William III., by act of parliament, in 1694; the idea having been taken from the Bank of Amsterdam, established eighty-five years before, whose success had been great, and its influence seductive. After the incorporation, which provided that the company should be under the management of a governor, a deputy-governor, and twenty-four directors, to be annually chosen, the business was for many years carried on at the Hall of the Grocers, in the Poultry.

It remained there some years, till the success of the undertaking had warranted the court of directors to purchase a piece of ground, covered with buildings of little value, in Threadneedle Street. Upon this a house was erected, on a comparatively small scale, to which the business was transferred in 1733; and soon afterwards, the present hall was opened, as well as the bullion-office. The façade was then extended under the direction of Sir Robert Taylor, and two wings were added, with the returns on the east and west sides, and several offices. In this work, it was found expedient to remove the church of St Christopher le Stocks, with the memorials of those who had been interred there. The whole of this enlargement gradually advanced from 1770 to 1786, when, by the death of Taylor, Sir John Soane became the bank architect, and he, in 1788, completed that part of the plan. Under the superintendence of his judgment and taste, the front and wings of the original structure were rebuilt in one harmonious manner; and various other alterations having been adopted, the whole was, in 1825, completed in conformity with the judicious designs of that most distinguished architect.

From the nature of the ground, fronting towards three public streets, on which it was practicable to intrude, the area is an irregular square, having a front of 365 feet on the south or principal side, and 410 on the north side, on the east side a front of 245 feet, and on the west of 440 feet; this is so managed, that it does not appear to be a defect, from whatever point the whole mass is surveyed.

The principal entrance is from Threadneedle Street, though there is one from Bartholomew Lane, and another from Lothbury. The interior contains eight open courts, the rotunda or circular room, numerous large and smaller offices, several committee rooms, and private apartments for the residence of officers and servants. The principal divisions and subdivisions of the structure are on the ground floor, and there are no rooms over the chief offices, whose height forbids the erection of such; but beneath there are capacious vaults, and a greater number of rooms than above ground. Within the building is an apartment for the guards, and a separate room for the officers who have the command.

It would require an elaborate work to describe all the particular beauties of this edifice, or the peculiar adaptation and arrangement of its offices for the management of the vast operations which are daily transacted; but to the adaptation of the offices to the purposes for which they are designed, the public are indebted for the order, expedition, and security with which every thing is conducted. The principal or great division, for several of them have subdivisions, are the great hall, the dividend offices, the discount-office, the bullion-office, the accountant's office, the chief cashier's office, the interior office or check upon forgery, and the parlour or apartment in which the directors assemble. All of these are neat, clean, and light, and some of them are elegant in their decorations and their furniture.

The Bank has, by successive renewals of its charter, since the first was granted in 1694, when the capital was L.1,200,000, been enabled to increase it to the present amount of L.14,553,000, which is lent to government at an interest of three per cent. The dividends on this capital have varied with the amount of profit gained by its various operations. At first it was 8 per cent.; in 1697, 9 per cent.; between that period and 1767, its fluctuations were frequent, but never lower than 4½ per cent. nor higher than 6 per cent.; in 1788, it was raised to 7 per cent.; in 1807, to 10 per cent.; in 1823, it was lowered to 8 per cent., and has continued at that rate to the present time. But besides the annual dividends, the directors have, at several periods, when any peculiar prosperity has attended the operations, distributed, under the name of bonus or some other, large sums to the holders of their stock, within the last thirty-six years.

The profit of the Bank is derived from various sources, which were laid before parliament, for the year ending the 29th of February 1832, were enumerated as follows:

Interest on commercial bills, ...	L.130,695
Interest on Exchequer bills, ...	204,109
Annuity for 45 years (dead weight), . .	451,415
Interest on capital received from the government, ...	446,502
Allowance received for the management of the public debt, ...	251,896
Interest on loans on mortgages, . . .	60,684
Interest on stock in the public funds, . .	15,075
Interest on private loans, ...	56,941
Profit on bullion, commission, rent, receipts on discounted bills unpaid, management of the business of the Banks of Ireland, of Scotland, and the Royal Bank of Scotland, and sundry items,	71,859
	L.1,689,176

The expenses of the Bank for the same year are thus stated in the parliamentary reports:—

Salaries and pensions, ...	L.218,003
House expenses, ...	30,187
Directors' allowance, ...	8,000
Rent, ...	40,000
Expenses of eleven branches arising from the banking department, ...	5,702
Expenses attending the circulation of L.2,500,000 of Branch Bank of England notes, at eleven branches, ...	28,508
	L.339,400

The amount of the notes of the Bank of England in circulation, has, since its establishment, varied from L.1,200,000 to L.30,000,000; of late years it has varied only between L.17,000,000 and L.24,000,000. The average during the last fifteen years may be taken at L.20,000,000; whilst the deposits of government, on the average, have been L.4,000,000, of which sum, thus amounting to L.24,000,000, one-third is estimated to be invested in bullion, and two-thirds in securities. By the parliamentary investigation which produced the preceding accounts, it appears that the balance of the Bank, or surplus property, in 1832, was L.2,637,760
To which is to be added the capital, . . 14,553,000

Thus leaving together . . L.17,180,760

a sum quite sufficient to make its stability as firm as the British government.

The following account will shew how much diffused is the property which is vested in the public funds, the dividends of which are payable at the Bank; and how much larger is the proportion in the hands of the middle classes than that belonging the large stockholders.

London.

An Account of the Number of Persons who were entitled to Dividends upon those portions of the Public Debt which became payable on each of the usual Quarterly Periods of the Year 1831 ; *arranged in various Classes, according to the Amount of Dividend to which they were entitled.*

East India House. The *East India House*, situated in Leadenhall Street, was first erected in 1726, but it has been gradually enlarged, so as now to form a building of vast size, accommodated to the various departments which the extent of the company's affairs require. Its principal front and a considerable part of the interior have been built within the last thirty years.

Towards Leadenhall Street it presents a front 200 feet in length, and having in the centre a portico of six Ionic fluted pillars, supporting a frieze with allegorical figures, and on the top a statue of Britannia. The interior has some fine apartments, especially the great court-room, in which meetings of the proprietors are held. The new sale-room is one of the most complete apartments in the city. It is adorned with pilasters, and with several appropriate paintings. The sale-room is also adorned with some fine statues of Lord Clive, Sir Eyre Coote, Sir George Pococke, and General Lawrence. The room of the committee of correspondence is embellished with views of Indian scenery, and with the portraits of Warren Hastings and of Marquis Cornwallis. The library is adorned with busts of the historian Orme and of Hastings; but is of inestimable value from the books, and especially the manuscripts, illustrative of the antiquities and the ancient and modern history of India, and other parts of Asia. The museum contains specimens of Indian arts and Indian curiosities of every kind, and especially the throne of Tippoo Sultan taken at Seringapatam. The company has several vast warehouses in different parts of the city. These they still retain; and, from their adaptation to the purpose, it is now in contemplation to occupy them as bonding warehouses for Indian and China articles.

East India Company. The East India Company was formed as a commercial body in 1599, and first obtained a charter from Queen Elizabeth in 1600. Although, in subsequent periods, the company acquired and extended vastly their territorial power, their commercial character remained to them until it was taken away by the law of 1835. They are now, therefore, a kind of board governing British India, under the superintendence of the Board of Controul chiefly, but with some power still left in the hands of directors chosen by the proprietors of India stock, whose dividends are guaranteed to them by the faith of parliament.

Trade with India and China. The following tables will show the value of the imports from, and the exports to, India as well as China, from the year 1820 to 1832.

An account of the Imports into Great Britain from all places to the eastward of the Cape of Good Hope (China excepted), in each year from 1820 to 1832, both included, distinguishing whether imported by the Company or by private Traders.

Year.	Value imported by the Company.	Value by Private Traders.	Total.
1820	L.1,737,137	L.4,201,389	L.5,958,526
1821	1,743,733	3,031,413	4,775,146

Besides the above articles there was an exportation of oreign cotton wool, in 1820, to the value of L. 93,402; of oreign skins, in 1823, 1824, and 1825, to the value of . 64,663; and of 54 bales of yarn, in 1829 and 1830, alued at L. 1291; whilst the annual stores sent out to the actory during the whole period of twenty-three years, mounted to L. 79,582.

The *Royal Exchange* is an edifice of more importance, rom the extensive mercantile affairs transacted within and round it, than either from its beauty or its extent, in both f which it is excelled by many other commercial cities. t the suggestion of Clough, who had been a clerk to Sir homas Gresham, and afterwards established as his repreentative at Antwerp, when that city was the great empoium of Europe, the knight undertook the construction of n exchange for London. It was completed in 1567, and was oon afterwards visited in state by Queen Elizabeth, upon hich occasion the title of Royal was conferred upon it. ll the upper parts were at that time filled with shops om the bottom to the top. That building was destroyed y the great fire of 1666, after which it was rebuilt in its resent form by a corporation of the city, and the company f mercers, at the expense of more than eighty thousand ounds. It was opened by Sir William Turner, lordayor, on the 28th of September 1669. In the new buildg the statue of Sir Thomas Gresham was placed within it, ut not in a conspicuous situation. There are also statues of harles I. and Charles II., and in the centre is a statue of Sir ohn Bernard, long the representative in Parliament of the ty, who gained and maintained his popularity by the tena- ty of his opposition to all the measures, whether good, bad, r indifferent, that were proposed by Sir Robert Walpole. he Exchange is a square, surrounded with arcades, and ivided into quarters assigned to the respective merchants ading to the different parts of the world, called the Scotch, rench, and American walks, or named from other countries; d some parts are known as the walks of different traders, ho did or might resort to them. These divisions are, owever, quite undefined, and by no means in practice so sed. Within the area there are no shops, but the walls are almost covered with placards, advertising sales of goods or of ships, and various other notifications. The outside all around is occupied by small shops, or by offices of brokers, notaries, and persons of similar calling. On the upper floor, on the north side, is Lloyd's Coffee-house, consisting of two long and lofty rooms, where the great business of insurance against losses by sea is conducted between brokers and underwriters. The society, who regulate this, employ agents in all ports, who furnish reports of the arrival and departure of vessels, and give the needful information as to the character, condition, and equipment of the ships. The accounts are registered accurately, and each subscriber has a book, into which are written, from time to time, by the clerks of the establishment, such descriptions of every vessel, as enable the underwriters to calculate the nature of the risk, and the premium it deserves. Upon the same floor is a large auction-room, an office for a jointstock insurance company, bearing the name of the building, and the office for the relief of sick and hurt seamen in the merchant service. An institution, called from the founder Gresham College, long occupied, or rather might have occupied, if hearers would have attended, a part of this floor. By will he left a part of his fortune to provide lecturers in divinity, astronomy, music, and geometry. Each of them had a salary of L. 100 per annum, but rarely delivered any lectures, as no auditors were in attendance. In consequence of this useless kind of expenditure, the trustees, in 1830, transferred the professors to the London institution, where, it is to be hoped, they may be found of benefit to the interests of science. The cellars under the Exchange are let out for warehouses. It has been calculated that, on an average, two hundred thousand persons daily visit the Exchange, but this can be little more than a guess. Much of the business which used to be transacted upon the Exchange has necessarily been divided, as commerce has gone on increasing; and the merchants and brokers resort much to coffee-houses in the vicinity of the building, which are distinguished by the names of the places with which the traders that frequent them have connexion, such as the East India, the New York, the Carolina, &c.

Most of the larger transactions are negociated by the means of brokers, who in general confine themselves to one branch of trade, with which their interest induces them to become thoroughly acquainted. Many of them embrace several branches; but those of the first class have large capitals or extensive credit, and are enabled to accommodate merchants with advances of money, or acceptances to a large amount upon the security of goods placed in their hands for disposal. In the West India trade some of them have large show-rooms, in which are exhibited samples of sugar, coffee, and the other tropical products. Ship-brokers are employed in buying and selling vessels, in hireing them by charter, in entering and clearing them out, in collecting the freights, and other business, which much abridges the labour, and saves the anxiety of ship-owners and ship-captains. Insurances, whether by joint stock companies, or by individual underwriters, are effected by the instrumentality of policy-brokers, who form a distinct class, and are paid by a commission of five per cent. on the premiums, and a fixed share of the profit which arises on the balance of their account with the underwriter. The rate of Exchange between London and the commercial cities in other parts of the world is fixed twice a-week between the drawers and the takers of foreign bills, and announced to the exchange-brokers at the close of each of the days.

Most of the brokers are licensed by the Lord Mayor and Court of Aldermen, but that does not apply to ship-brokers, nor in actual practice to most of the stock-brokers. Those so admitted must give security for the due performance of the duties entrusted to them, and not deal or make gain in goods; but it is apprehended this last condition is more generally broken than observed. There is a class of brokers which has come into existence within a few years, who are said to have made fortunes of an enormous amount. They are usually called bill-brokers, but are properly money-brokers, employed in arranging negociations in money matters of a large amount, between bankers, merchants, and others, who, in the fluctuating nature of their trade, either have occasion to lend or to borrow money upon indisputable security. Though the commission paid to such brokers is small, yet the extent of the transactions have made it a lucrative business.

Stock Exchange.

Near to the Royal Exchange is another institution called the *Stock Exchange*, wherein bargains are made for the real purchase and sale of property in the public funds, and where is carried on the enormous business of buying and selling stock for a future day, at a fixed price in speculation, as it is delicately called, though in fact, for the most part, it is only gambling upon a large scale. The house is near the Bank, and is conveniently arranged, and handsomely fitted up. It was erected in 1804, at the expense of the subscribers, who elect a committee to manage the affairs, and who have power to make regulations, and to admit or expel such members as they please. Near to it is the market for foreign funds; and in the rotunda of the Bank of England is a crowded assemblage, who carry on some real, but more gambling, transactions in public securities.

Having noticed those establishments in London which are chiefly subservient to the commercial intercourse between the metropolis and foreign countries, we proceed to mention others, whose main object is internal, though it extends also to external affairs.

Post-office.

The *Post-Office* is one of those institutions which in this country has arrived the nearest to perfection, and is not only worthy of the talent by which it has been advanced, but justifies the pride which its consideration inspires. It is not necessary here to trace the history of the establishment from the commencement, in the reign of Charles I., 1635, nor the advances it made up to 1784. At that period the letters were conveyed with dilatory irregularity which was the inducement of Mr Palmer of Bath to suggest and arrange a plan for the conveyance of letters by coaches. After due consideration, the experiment was first tried between London and Bath, and was found to be so safe, so quick, and so economical, that the scheme was in due time adopted, and every part of the kingdom in a few years became participators of the benefit, whilst the State drew from it a constantly progressive revenue. In 1783 the net proceeds of the Post-Office did not exceed L.145,000 per annum, and it now regularly yields about ten times that amount.

The old post-office in Lombard Street had been long complained of as inadequate, or ill adapted to the extent which the establishment had acquired; for it had grown, under the direction of Mr Palmer, first as comptroller, and of Mr, now Sir Francis Freeling, as secretary, to such a scale, that though buildings near to it had been added, the want of room prevented the most beneficial arrangement of the several branches of the institution.

The site chosen is central, sufficiently near for the purposes of commerce, and much nearer to the offices of government than the former spot. This magnificent but simple edifice was begun in St Martin's le Grand, in 1825, and the business transferred to it in 1829. It is of the Grecian Ionic order of architecture. The basement is of granite, but the superstructure is of brick, faced with Portland stone. The building is in length 400 feet, and in breadth 80 feet. The portico in the centre of the front is 70 feet broad, consisting of six columns of Portland stone, resting on pedestals of granite, and supporting a triangular pediment, beneath which is this inscription, "Georgio Quarto Rege," and the date in Roman capitals, "MDCCCXXIX." At the extremity of each wing is a portico of four columns. In this front are forty-four windows. The east front is quite plain, and has upwards of 180 windows.

Under the centre portico is a vestibule of noble effect, on the north side of which are the receiving rooms for letters, and apartments for the sorters of inland letters. These extend the whole length. The mails are received at the east front. The foreign-office is on the south side, as well as the offices of the receiver and accountant. At the east end of the vestibule are the twopenny offices. The sorters' room is an apartment of forty-six feet by twenty-four, in which their operations are performed with a dispatch and regularity that is astonishing. A novel mode has been adopted for conveying letters, which have come into the wrong department, from one room to another; they are placed in small waggons beneath the pavement, and made to travel through a tunnel by machinery.

The whole building is fire proof, and machinery conveys coals and water to every part of the building. The whole is lighted by gas, and is furnished with more than one thousand burners. The assistant-secretary has a residence in the building, and in the upper rooms are apartments for the clerks to sleep in, as they are necessarily up early to receive the mails.

As the business of this office must be performed in the space of two or three hours in the morning, and the same period in the evening, it demands a regular system for the sorting of so many letters. The average is about 46,000 letters, which arrive at six in the morning, and these are generally counted, examined, charged, and delivered to the letter-carriers by half-past eight or nine o'clock. In the evening the same number is received at the windows, and must be dispatched before eight o'clock. As the greatest number is received just before seven, the greatest expedition is used to complete the whole operation. The letters are first arranged as they arrive from the receiving-houses in different compartments, marked with the name of the mail by which they are to be sent, which is performed by the unior clerks. The senior clerks then mark on each letter he amount of postage, which is done at the rate of one econd of time for each letter, and the letters are placed n boxes labelled with the names of the towns. The reeiving-office is closed at seven o'clock, when the letters or each town are summed up, and the summation put in he bag with them. Letters may be sent later than seven, y paying a fee, which is allowed as a perquisite to the unior clerks. The bags of letters are tied, sealed, and devered to the several guards at eight o'clock.

The delivering of the letters in the morning is expedited by means of *accelerators* or light-built carriages first used when the new building was occupied. A postman, or rather coachman, in these takes different divisions of the town, and drops the letter-carriers, with the letters, in their various walks, which saves the difference of time between walking and riding, and produces a most expeditious delivery in the most distant parts of the metropolis. The inland office employs about 200 clerks and sorters, and about the same number of persons for the delivery of letters. The foreign office has twenty clerks, and thirty-four for the delivery. The two-penny post employs about fifty persons.

An Account, shewing the Produce of the Post-Office Revenue, together with the Charges of Collection, in each year from 1820 *to* 1834, *both inclusive.*

Year.	Gross Receipt.	Returned Letters and Overcharges.	Net Receipt.	Charges of Collection.	Net Revenue.
1820,	L. 2,144,678	L. 76,616	L. 2,068,061	L.588,514	L. 1,479,547

1824,	2,262,814	79,267	2,183,547	594,874	1,670,219
1825,	2,367,567	91,360	2,276,207	605,988	1,624,256
1826,	2,392,272	87,469	2,304,802	680,546	1,501,056
1827,	2,278,412	83,663	2,194,749	693,692	1,544,223
1828,	2,287,961	79,962	2,207,998	663,774	1,588,672
1829,	2,265,482	80,815	2,184,667	675,319	1,509,347
1830,	2,301,432	89,226	2,212,206	694,254	1,517,952
1831,	2,321,311	93,947	2,227,364	658,325	1,569,038
1832,	2,277,274	101,983	2,175,291	643,464	1,531,826
1833,	2,294,911	104,729	2,190,181	636,755	1,553,425
1834,	2,210,830	110,541	2,100,299	650,962	1,449,337

As the post-office is peculiarly a department of expendire as well as of revenue, much care and attention is apied in making the contracts with those who convey the ails, and great economy in adjusting the appropriate saries to the different officers. This is clear from the numer of persons employed under the postmaster-general, being more than 3000, with from 4000 to 5000 horses, and near 200 coaches. The packet service costs L.115,000 yearly; the mileage to mail-coaches, and the payments to guards, tolls, &c. amount to about L.72,000; and the expense of conveying letters to Nova Scotia, Canada, and Jamaica, to which parts the packets do not go, costs L.12,500.

An Account of the Amount of Postage collected at the principal Cities and Towns of the United Kingdom, in the years ending the 5th January 1833, 1834, *and* 1835.

The *Mint*, on Towerhill, is a simple, elegant, and extense building, erected within a few years, under the directn of that eminent architect, Smirke. It consists of three sreys, having a centre ornamented with columns, and a pdiment displaying the British arms, and two wings with pasters. Within the enclosure is a house for the master, ad accommodation for the other officers of the establishment. The interior is appropriately arranged for the manfactory of coined money, all of which is executed by the best machinery, invented by Bolton, with some recent improvements. The whole is put in motion by a steam-engine, and lighted by gas, and is capable, in case of need, of coining a vast quantity of coin in an almost incredibly short space of time. Strangers are only admitted to see it upon some special recommendation of the superior.

The amount of gold and silver money coined here in the last seventeen years has been as follows:—

Year.	Gold.	Silver.	Total.
1818,	L. 2,862,373	L. 576,279	L. 3,438,652

Excise Office.

In Broad Street is the *Excise Office.* It was originally the property of that eminent merchant Sir Thomas Gresham, and is remarkable as being the spot upon which the Royal Society was founded. It was begun here from Wilkins, afterwards Bishop of Chester, having apartments in it, at which, in 1658, meetings were held of scientific men, consisting of Dr Ward, afterwards Bishop of Salisbury, the great and good Mr Boyle, Sir William Petty, Doctors Wallis, Goddard, Willis, and Bathurst, and Sir Christopher Wren, with a few more. Such were the founders of that society which has done so much for the promotion and diffusion of scientific knowledge, and whose fame is only bounded by the limits of the civilized world. It 1711, it was removed from this place to Crane Court, Fleet Street, and thence to the present apartments in Somerset House. Gresham House was, after the great fire, converted into alms-houses, which were sold to government in 1763, and on the spot was built that extensive structure now used by the commissioners of the excise branch of the public revenue. It is a capacious edifice, consisting of two ranges of building, separated by a court-yard, and connected by a passage through it with Bishopsgate Street. It is well arranged in the interior for the dispatch of business, which greatly facilitates that regularity, expedition, and security which peculiarly distinguish that portion of the public service.

Trinity House.

An institution, which has proved of vast benefit to the art of navigation, has its chief establishment on Tower Hill, and is called the *Trinity-House.* This society was founded in 1515, when the British navy first assumed a systematical form, by Sir Thomas Sport, who was comptroller of the navy, and commander of the great ship *Henry Grace de Dieu.* It was first established at Deptford, Strand, under the name of "the Master, Wardens, and Assistants of the Guild or Fraternity of the most glorious and undivided Trinity." In process of time it has acquired large property, and the members being chosen partly from the highest ranks, but chiefly from men of skill in the naval profession, it is a body highly respectable and useful. Its members are frequently seated with the judges on the bench to assist by their advice in maritime affairs. They examine and nominate pilots, superintend the light-houses, buoys, and land-marks, regulate in London the ballasting of ships, examine the masters of his Majesty's ships of war, and superintend the mathematical studies of the youth of Christ's Hospital. The corporation now consists of a master, four wardens, eight assistants, and eighteen elder brethren; and though they retain the old house at Deptford, where they have an hospital for decayed masters of ships and their wives, they hold their chief sittings at their new house. As they are the guardians of many charitable funds, they yearly relieve the distress of numerous poor seamen and their families. Their elegant house was built in 1793 by Wyatt. It is of Portland stone, with a rustic basement, over which is one storey adorned with Ionic columns and pilasters. In it are many portraits of eminent naval men, particularly of the celebrated Admiral Sir John Leake, who distinguished himself at the battle of La Hogue, and captured Gibraltar, Carthagena, and Minorca, in the reign of Queen Anne. There are also preserved captured flags and other naval trophies.

Distribution of articles of foreign commerc

Hitherto attention has been directed to the commerce of the metropolis, and the institutions connected with that part of it, which is carried on by maritime means. It will now be proper to notice the distribution of the various articles which foreign commerce conveys to London. It has already been observed, that the intervention of brokers is had recourse to in mercantile transactions; but between the merchants and consumers, there are other classes of traders who constitute an important part of the inhabitants of the metropolis. This may be best described by taking some prominent article of commerce, and attending to its distribution; and as sugar is one of the largest amount of any commodity brought by sea, it is best adapted to the purpose we have in view. The West India merchants import it by ship-loads, but in the ships are various qualities, according to the plantations which produce it. Upon their landing, samples are exhibited of the different qualities, classed according to their value, upon boards by the brokers. The wholesale grocers purchase the sugars by boards of ten, twenty, or forty hogsheads at a time, and then sell them to the retail grocers, whose demand is limited, by single hogsheads, or by portions of hogsheads. The profit of the intermediate wholesale grocers is generally small, but as the amount is large, and the return quick, it is generally a lucrative trade. It facilitates the great operations of the importing merchant, and accommodates the condition of the retailer, and these middlemen or wholesale grocers being generally possessed of large capitals, buy with ready money, and sell on credit, which, though short, is of great service to the retailers, who are commonly less provided with capital. If the wholesale grocer can return his capital three or four times in the year, with but a profit of two per cent. beyond the interest, he is amply repaid for the use of his capital, and the increase of his profit is scarcely felt by the consumer. It is not necessary here to entertain the question, whether it would not be better for a community that all transactions in commerce should be conducted solely by ready money; our object being rather to shew the existing mode, than to indulge speculations on a supposititious arrangement under a different state of affairs.

The other great articles of commerce are distributed in the same manner as sugar. Thus tea is bought at the India House by the wholesale tea-dealers in lots of several chests, and sold by them to the retailers in single chests, or part of chests; so are currants, raisins, figs, coffee, spices, rice, and in a great degree wine, rum, brandy, and gin. There are, indeed, a few in each branch of trade who are both wholesale and retail traders; but they form the exceptions, not the rule.

In a similar way the wholesale traders of the metropolis become the channels for conveying the articles manufactured in one part of the kingdom to the retailers, and the latter to the consumers in the other parts of it. Thus wholesale houses in London collect the cloths of Yorkshire; the stuffs of Norwich; the cottons of Lancashire or Scotland; the linens of Ireland, or of the northern counties; the iron-ware of Birmingham; the cutlery of Sheffield; the pottery and porcelain of Staffordshire; the bottles of Northumberland; the ribbons of Coventry and Leake; and the hosiery of Nottingham, Leicester, and Derby; and from their warehouses, by the assistance of their travellers, they supply the chief demand of the shopkeepers in the smaller towns in the southern and western counties of England.

Thus London, from the capital possessed by its merchants, its easy accessibility from every part of the kingdom, and the facilities of direct conveyance to and from it, has become a trading place far beyond what its own production and consumption could ever have created. The system of banking pursued in London is peculiarly favourable to the interest and the convenience of the intermediate trade. There are seventy private banking houses in the city and its adjuncts; most of the traders keep accounts in them; and the surplus money of some accounts is used to discount bills for those who need it, whilst acceptances for goods sold, the practice of giving which has vastly increased, can easily be converted into money. The bankers can spare a greater portion of their balances than they could do if they were liable to general calls for it; but that is not much the case, from the establishment created among the bankers called the clearing-house. At that place, near Lombard Street, each banking house sends a clerk with the checks on other houses received in the course of the day, and there exchanges them with the checks drawn upon them. By this exchange of paper, sums of enormous magnitude are paid and received mutually, with the use of only a small sum of money, or of Bank of England notes. In fact, in London, generally speaking, there is much less money left in a state of absolute rest, than in proportion to its amount is to be found in any other of the commercial cities of Europe.

The ease and certainty with which assorted cargoes for ships bound to foreign markets can be furnished is a great advantage to London, and particularly to that intermediate class of traders called warehousemen or wholesale dealers. There is no product of any part of the United Kingdom, none of those of the most distant parts of the globe, that may not be obtained in London, without causing any detention to the departing vessels, and without any great advance in the price beyond the cost of conveyance.

Although London, when compared with some of the towns of the north of England and of Scotland, can scarcely be entitled to the name of a manufacturing place; yet the various articles fabricated in and around it, afford great occupation to numerous individuals; and they have been the nurseries in which the most important branches of national industry have received their birth and their first growth. The silk trade is that which at present gives employment to the greatest number of hands. This was originally introduced by French Protestant refugees, many of the descendants of whom still continue the trade of their ancestors. The number of persons employed in the several operations of dyeing, winding, warping, and weaving silk, a large proportion of whom consists of females and children, is estimated at 48,000. The new-fashioned goods and the fancy articles are mostly made here; and any kind of goods that happens afterwards to become much in demand, is soon made, where food, fuel, and labour are cheap, upon which it ceases in London. The change of fashion and the variation of taste is so frequent, that the silk-weavers do not decline in the metropolis, notwithstanding the numerous power-looms which make silk goods in the other parts of the kingdom. The good effects of the nurture which the metropolis affords to infant fabrics, may be illustrated by some facts relating to the silk trade. In the middle of the last century, silk gauzes were exclusively made in London. But some disturbances amongst the weavers, caused a family or two whose property was embarked in that business to remove to Scotland in the beginning of the reign of George III. They there established the silk gauze trade, employing operative weavers, who had been occupied in making gauzes of flax, commonly known by the name of Scotch lawns or clear lawns. The attempt succeeded, and soon became so extensive that the great and flourishing town of Paisley owes its present state to this circumstance. The effect of this early nurture of the trade did not stop with itself. In a few years, the fashion of wearing silk began to decline, and the experiment was tried to turn the hands who had woven silk gauzes to the kindred manufactory of muslins like gauze, but made of cotton. Book muslins, as they were called, and afterwards other sorts of muslin, were then fabricated: a trade on the extent and value of which to the whole kingdom it is unnecessary here to expatiate.

There are numerous small articles which are either made exclusively in London, or which, having the name of "town made," are better reputed than any others. Amongst the first are silk fringes, coach lace, gold and silver lace, lapidary articles, Prussian blue, and some others; amongst the latter, as is well known to all ladies, are needles, pins, fine scissors, and penknives, to which may be added musical, mathematical, and surgical instruments; brushes, combs; clocks, watches, jewellery of the superior kinds, gold and silver plate; ornamental and useful furniture, coaches and other carriages, saddlery, painters' and dyers' materials; numerous medicinal and chemical preparations, particularly magnesia, aquafortis, sal-volatile, essential oils, and other articles.

Trades.

The publication of books is a great trade in London. The population return of trades is necessarily indistinct; but, according to it, there are 8950 males above twenty years of age, who are booksellers, printers, binders, or otherwise employed. It gives subsistence to about 50,000 individuals. The tailors and shoemakers furnish with their respective articles of dress many who do not reside in London, and many even in the colonies and in India. The numbers of the tailors are stated at 13,783. Those of the shoemakers and menders amount to 15,274; but the chief part of the shoes furnished to London are made at Stafford, Northampton, and Newcastle-under-Line. The bakers are stated at 5209; the butchers at 4069; the carpenters, 12,254; the cabinet-makers, 4921; the publicans, 4804; the upholsterers, 1724; the glaziers and plumbers, 2272; the bricklayers, 4874; the house-painters, 4439; the blacksmiths, 4106; the whitesmiths, 1822; plasterers, 1725; and the stone masons, 1592.

As these numbers relate solely to males above twenty years of age, they can only be used for the purpose of comparison; but as females are excluded, and all males below twenty, we may perhaps be justified in assuming that the number of individuals subsisting by means of these professions may be multiplied by four.

It is obvious to remark the great number of persons employed in the construction or reparation of buildings, and the proportion they bear to those engaged in other kinds of industry. This seems to show that the metropolis is still most rapidly advancing in improvement, as it must be in wealth, since the erection of new houses of any kind is the best evidence of a previous accumulation of capital.

Quantity of provisions consumed.

The next object of attention is the quantity of provisions consumed in London annually, and the means by which supplies are procured. The annual supply of cattle, in the last ten years, has been 153,228; that of sheep, 1,265,958; that of fatted calves, 20,780. The pigs are estimated, but little faith can be placed in the calculation, as one-tenth of the number of sheep. If the weight of the cattle be taken at 300 lbs. on the average, and the offal be taken at 200 lbs., the weekly amount consumed will be 1,766,092 lbs. If, in the same way, the weight of the sheep be taken on the average at 80 lbs. each, and the offal at 20 lbs., the weekly weight consumed will be 2,035,788 lbs. The calves, averaging 140 lbs., with 35 lbs. allowed for offal, would give a result of 61,191 lbs.

Thus, taking the whole into view, the weight appears to be:—

Of beef, . . .	1,766,092 lbs.
Of mutton, . . .	2,035,788 ...
Of veal, ...	61,191 ...
To this may be added for pork, one-twentieth the weight of mutton, .	101,787 ...
	3,964,858 lbs.
There is also brought to London a large quantity of bacon hams, tongues, and other salted meat. A portion also of the offal, as tripe, liver, and other parts, is used as human food, and so are sausages. These may be estimated as equal to one-tenth, or .	396,485 lbs.
	4,361,343 lbs.

We thus arrive at a weekly consumption of 4,361,342 lbs., or to a daily consumption of 623,049 lbs., being, for 1,800,000 persons, 5½ ounces per day, or 109 lbs. yearly. The statistical accounts of Paris give, as the annual consumption of each person in that city, 86 lbs.; and at Brussels the estimate is three pounds higher, or 89 lbs. In no other city of Europe, excepting perhaps Hamburg, does the consumption reach so high as in Paris.

The preceding remarks on animal food are only made for the sake of comparison, and not to obtain great confidence. The only actually ascertained facts are the numbers of the oxen and sheep, all the rest being estimate or conjecture. It is well known that cattle are purchased at Smithfield, and driven to the towns near London to be slaughtered, and that many cutting butchers in such towns buy cattle of the carcass butchers in London. From many distant towns much meat is sent to the metropolis, when cut into joints. The legs with the loins of sheep, and the best parts of the roasting pieces of beef, are sent by coaches to the butchers of London, and the inferior parts of the same animals are sold in the country markets. All this makes any calculation, whatever foresight may be applied to the subject, very uncertain and doubtful. The weekly account of sales here quoted only applies to the animals brought to Smithfield, of which an account is taken by the city authorities. The sales have not increased with the increase of the population, and chiefly because other markets recently rising, the amount of sales in them has increased. One of these is at Southall, on the Uxbridge road; another at Balls Pond, Islington; and one near Croydon. Of these no accurate account can be obtained.

Quantity of corn consumed.

The quantity of corn consumed in London is as difficult to be ascertained as that of meat. The market of Mark Lane, where, in two buildings of handsome appearance and commodiously fitted up, the principal transactions in grain and flour are conducted, is no criterion of the quantity actually consumed. There are speculations at times going on, which baffle all conjecture. Besides, much of the bread made in London is compounded of flour brought by sea from the northern parts of England, and some even from Scotland and Ireland. Most of the mills which supply the best flour are either in the vicinity of London, or at such a distance that a waggon and horses can go and return within the day. On the river Colne, from Walford to the Thames, are several powerful mills. On the river Wandle, in Surrey, are also some; and there is one enormous mill at Wandsworth, partly worked by steam. The Thames below London conveys to it much corn and flour; the best of both is brought from the shores of Kent and Essex; but much comes from the more distant ports in the counties of Suffolk, Norfolk, and Lincolnshire. The supply of oats is chiefly obtained from Lincolnshire and the rich marshes of the Isle of Ely, which export at Wisbeach or Lynn. Barley is generally supplied from the turnip farms of Norfolk, and from the lands of the lighter kinds in Cambridgeshire, Hertfordshire, and Bedfordshire; but much of it is made into malt before it is sent to London. According to the accounts of the inspector of corn returns, the quantity sold in London has been as follows.

An account of the quantities of British Wheat, Barley, and Oats, sold in the London markets in each year from 1825 *to* 1835, *both years inclusive.*

Year.	Wheat.	Barley.	Oats.
	Qrs.	Qrs.	Qrs.
1825	317,875	239,676	572,640
1826	240,920	161,124	391,386
1827	232,202	156,629	279,204
1828	287,209	201,533	1,064,000
1829	156,770	183,256	1,077,326
1830	214,032	247,015	772,405
1831	222,514	218,460	867,463
1832	362,495	271,107	1,165,737
1833	373,730	325,508	1,067,314
1834	409,241	311,962	1,123,593
1835	381,188	258,744	1,247,975

Supply of fish.

London is well supplied with fish of all kinds, according to the season. The greater part is brought by vessels to the wholesale fish-market at Billingsgate, in Lower Thames Street. Many of these vessels are Dutch, which catch the fish, chiefly turbot, on the Dogger Bank, and convey it to market; but much is taken by our own fishermen. From Scotland, abundance of salmon, in the proper months, is brought to Billingsgate, packed in ice. In some years there have been imported from Norway as many as 1,200,000 lobsters, and some from Heligoland. There is no duty upon turbot or lobsters, but all other fish, if not caught by British fishermen, are prohibited. At some periods great quantities of fish, chiefly mackerel, are brought to London by land-carriage. Large quantities of cured fish are furnished to the metropolis, such as the salted cod brought from Newfoundland, the smoked and the salted herrings caught in Scotland, and on the shores of Norfolk and Suffolk. The fish trade still centres in the city at the old market of Billingsgate, an attempt to establish a market of competition at Hungerford having hitherto failed. The trade is carried on chiefly by means of salesmen, who contract for the cargoes as they arrive, and retail them out to the fishmongers, of whom there are 950 scattered about in every division of the metropolis and the contiguous villages. The oyster fishery depends chiefly on the demand in the metropolis, where only the best can be obtained. The feeding of them is carried on chiefly at Colchester, to which neighbourhood they are brought from the shores of Hampshire and Dorsetshire, and laid down in beds on creeks, to grow and fatten during two or three years. The trade employs about 200 vessels of from fifteen to forty-five tons burden. The quantity caught of late years has been from 14,000 to 15,000 bushels. The packing them in small barrels as presents, is a considerable trade. The quantity of fish brought to London has been estimated at 50,000 tons weight annually, but with what degree of correctness this is stated, we have not ascertained.

Products of the land around London.

The land around London is much too valuable to be destined for the growth of corn. Whatever may have been the original quality of the soil (and it was probably once very poor), the draining in the swampy parts, and the vast quantity of manure which a great city supplies, has made it some of the most productive in the kingdom. It is, however, chiefly devoted to feeding cows, whose milk must be brought fresh to the consumer, or in growing such delicate fruits and vegetables as are injured by long keeping or long carriage. The number of cows kept for milking is

ondon

calculated at about 12,000, yielding about 10,000 gallons of milk, which is supplied at each house twice a-day out of tin pails. The grass-land is hardly sufficient to feed that number, and some part of their food, besides hay, consists of grains from breweries, and often of Swedish turnips or mangel wurzel, brought from farms at a distance.

Except this feeding land, the greater part of the soil is appropriated to nurseries or horticulture. The first yields flowers in abundance, and young plants of the various kinds proper for gardens. The latter produce the best of culinary vegetables that are required for daily use in the metropolis. The more delicate kinds used for salads are eminently good. The lettuces, especially, are more approved than any grown at a distance from London. Cabbages, broccoli, cauliflowers, and other plants of the Brassica tribe, are deemed to be more appropriate products of the soil and atmosphere of the vicinity of London, than of any other parts of the kingdom.

Those fruits which are of the most perishable kind are grown nearest to London, particularly raspberries, strawberries, and cherries in their season. These are commonly gathered at a very early hour in the morning, and sent to the first-rate fruit shops, on the heads of women, mostly from Wales, and are ready quite fresh at the hour of breakfast. Gooseberries, currants, and the common wall-fruits are amply supplied. The vegetables from Chelsea, Hammersmith, Fulham, and on the banks of the river are conveyed for the most part by the river Thames, and consigned to Covent Garden and the other vegetable markets, where they are met with those products that arrive in carts. They are generally sold by salesmen or factors, and then distributed throughout the metropolis by a class of small traders denominated green-grocers.

The more common and less perishable vegetables, such as potatoes, turnips, carrots, and parsnips, are grown at a greater distance, but are brought to the same markets, and are dispensed to the consumers in a similar manner. It may here be remarked, that the vicinity of Gravesend is celebrated for the excellence of its asparagus and artichokes, the greater part of which is conveyed to London by the steam vessels. Not far from that place is a kind of farm which could be profitable nowhere but in the vicinity of a great city. A few acres are destined to grow watercresses. These are gathered early every morning, bound up in small bunches, and despatched by a light cart to London, where it arrives by the hour of breakfast, and is distributed by persons who cry them through the streets for sale. Poultry is abundantly if not cheaply provided; but if dear, it is remarkably good. Higglers travel the country round London and purchase fowls in the lean state. These are carefully fattened at some large establishment for that purpose in the eastern side of London. Pigeons are also kept for poulterers' shops, and many tame rabbits. Of late hares, pheasants, and partridges have been allowed to be sold, and are obtained at moderate prices. These articles furnish subsistence to about 350 traders, known by the name of poulterers, who sometimes unite with them the dealing in butter, eggs, and sausages.

kets.

The markets in the metropolis are numerous, but the most considerable of these can here receive no other attention than mentioning their names and localities.

ent-
len.

Covent-Garden has been already noticed as the place for vegetables. It is the centre of a square, and has been newly built within the last six years by the Duke of Bedford, the proprietor. It is an elegant and commodious structure, with two ranges of shops running from north to south, and three from north to south. In these and in the open parts of the market the display of fruits, flowers, and vegetables, especially at an early hour of the morning, is a very gratifying spectacle. Its situation is convenient, and the access to it from every side peculiarly easy.

London.

Newgate.

Newgate market is one of the largest, dealing much by wholesale both in meat and vegetables. There are many carcass butchers who sell the whole animals when slaughtered, without the skin, tallow, and entrails, to others in the same market, or in other parts of the town, who sell it by the joint, and are distinguished by the name of cutting butchers. There are also salesmen as well as retailers of fruit and vegetables. The great or wholesale markets are on Monday, Wednesday, and Friday.

Leadenhall.

Leadenhall market rivals that of Newgate in the number and extent of the carcass and cutting butchers, and excels it in the trade of skins and leather. A new market called Farringdon has been constructed to supply the want of Fleet market, which has been removed to form a good avenue. It is large, covering more than an acre of ground, and the building, which was finished in 1829, cost the corporation of the city L.200,000. It is very commodious, but hitherto not filled with sellers and buyers.

Hungerford.

Hungerford market has been built only two years, on the site, but enlarged, of a former market. It is an elegant and commodious structure, most appropriately fitted up. As it stands on the bank of the Thames, and has convenient access to the water by stairs, it was expected that the vessels with fish would come up and discharge them; but that expectation has not been fulfilled, nor are the greater part of the shops occupied. It was built by a joint stock company. The length of the interior is 140 feet, and the breadth 70. The front to the river has a fine appearance.

Other markets.

The great markets for hay and straw are held in Whitechapel, in Smithfield, in the Borough, in the Haymarket, and near the Paddington canal. The other markets are Newport for butcher-meat, Borough for meat and vegetables, and Honey Lane for the best qualities of their several kinds of food; Clare, Cumberland, Fitzroy, Grosvenor, Hoxton, James, Oxford, Red Lion, Mortimer, Tottenham Court, St Luke's, St George's, Shadwell, Sheppard's, Brooks, and Chelsea, are all of them markets upon a retail scale, but sufficiently supplied to accommodate the population in their immediate vicinity with what they require.

The class of tradesmen called cheesemongers, of which there are 1395 in the metropolis, deal chiefly but not all of them exclusively in butter and cheese. Some of them add to their proper trade that of selling hams, bacon, and tongues. The sale of butter is said to be 24,650 pounds, and that of cheese to be 26,700,000; but this must at best be a doubtful estimate.

The mode by which the poorest classes are supplied with food, according to the power of purchasing it, is by small shops scattered through every part of the outskirts of the town. In some of these, small portions of meat, or of puddings, or of vegetables may be obtained ready cooked, at very low rates. In some parts these are in cellars, which are the most homely and cheapest. Of late a practice has prevailed of carrying about potatoes ready boiled, and kept warm, which are sold to the most destitute, who can only command a penny or even a halfpenny, and with that can purchase a meal, though a very scanty one.

Water companies.

No city can become large unless it is built on the banks of a river which abundantly supplies it with water both for drinking and for cleanliness; and when it becomes extended far from the river, the expense and the labour to be applied to afford a supply of water to such parts is very great, especially if, as is almost always the case, the ground rises in height as it is more removed from the stream. Although London is supplied with many excellent springs of fresh water, they were early found to afford an insufficient supply, and, besides, the water was not fitted for many purposes. Various means have been adopted to secure an adequate portion of water, each of which deserves notice; but the most prominent is that which still affords nearly one-half the quantity that is consumed.

In the early part of the reign of James I., Sir Hugh Middleton, a citizen of the Goldsmith Company of London, undertook at his own risk and charge to convey to the elevated hill above the city a river of fresh and good water. He began the work in 1608, but the city refusing to embark in the undertaking, the King covenanted to advance money for the purpose on condition of half the property being conveyed to him. This agreement was made in May 1612, and in September 1613 the water was let into the basin at the place now called the New River head at Islington. From thence by subsequent labour it was at length conveyed by pipes underground to the several streets and houses that required it. Since that period the company has augmented its supply first from the river Lea and then from other sources; and the concern has proved highly beneficial to the company. The principal supply is obtained at Amwell in the county of Hertford, whence preserving the level so as to have only a fall of two inches in a mile, it flows forty miles with a gentle motion, and in that distance passes under 200 bridges, until it reaches the main large or circular reservoir whence it is distributed to the inhabitants.

The next attempt to supply water was by the Chelsea Water-work Company in the year 1723; and these two, with some aid from machinery at London Bridge, continued to supply the north side of the Thames till 1810, when three new companies, the East London, the West London, and the Grand Junction, were established by authority of different acts of Parliament.

The following account from Wade on the Police will best describe the operations and practical effects of the companies. The progress of the New River has been noticed. There are at Clerkenwell two reservoirs having between them a surface of about five acres and a depth of ten feet. These reservoirs are 84½ feet above low water-mark in the Thames. and by means of steam-engines and a stand-pipe an additional height of sixty feet can be given to the water; so that all the mains belonging to this company are kept full by a considerable pressure of water. The highest service given by the New River is the cistern on the top of Covent Garden theatre. The aqueduct by which the water is brought has only a fall of two inches in a mile; thus it wastes by evaporation in summer, and is impeded by frosts in the winter. At such times the company pump an additional supply from the Thames at Broken Wharf, between Blackfriars and Southwark Bridges. To this, however, they seldom have recourse, and their engine, erected since the works at London Bridge have been removed, has worked only 176 hours in the year. The New River Company supply 66,000 houses with water at an annual average of 1100 hogsheads each, or, in all, about 75,000,000 hogsheads annually.

The East London water-works are situated at Old Ford, on the river Lea, about three miles from the Thames, and a little below the point to which the tide flows. By the act of parliament this company must take its water when the tide runs up, and the mills below have ceased working. The water is pumped into reservoirs, and allowed to settle, and a supply of 6,000,000 gallons is daily distributed to about 42,000 houses. This company supplies no water at a greater elevation than thirty feet, and the usual height at which the delivery is made to the tenants is six feet above the pavement. They have 200 miles of iron-pipes, which, in some places, cost them seven guineas the yard. This and the New River are the only companies that do not draw their supply wholly from the Thames.

The West Middlesex Company derive their supply of water from the Thames at the upper end of Hammersmith, 9½ miles above London Bridge, where the bed of the Thames is gravel. The water is forced by engines to a reservoir at Kensington, 309 feet long, 123 wide, and 20 deep, which is paved and lined with brick, and is elevated 120 feet above low water in the Thames. They have another reservoir on Little Primrose Hill, about 70 feet higher, and containing 88,000 hogsheads of water, under the pressure of which the drains are kept charged in the event of fires. They serve about 15,000 tenants, and the average daily supply is 2,250,000 gallons.

The Chelsea water-works derive their supply from the Thames about a quarter of a mile east from Chelsea Hospital, and they have two reservoirs; one in the Green Park near to Piccadilly, and another in Hyde Park near to Mount Street, the former having an elevation of 44, and the latter of 70 feet. These reservoirs till very recently had never been cleaned, nor had any preparation been made for that purpose in their construction. About one-third of the water served out by this company is allowed to settle in these reservoirs, and the remaining two-thirds are sent directly from the Thames. This company has recently constructed works by which they can filter their water by passing through successive beds of stone and sand before it is sent to the reservoirs. The Chelsea Company serves about 12,400 houses, and their daily supply amounts to 1,760,000 gallons.

The Grand Junction Company derive the whole of their supply from the Thames immediately adjoining Chelsea Hospital, whence it is pumped without any filtration or settling into three reservoirs at Paddington. These are respectively about 71, 86, and 92 feet above high water-mark in the Thames; their united contents are 19,355,840 gallons; and by means of a stand-pipe the water is forced to the height of 147 feet, or about 61 feet above the average height in the reservoir. The number of houses supplied by the Grand Junction Company is 7,700, and the average daily supply of water is 2,800,000 gallons.

The Lambeth Company take their supply from the Thames between Westminster and Waterloo Bridges. It is drawn from the bed of the river by a suction-pipe, and is delivered to the tenants without being allowed to subside, there being only a cistern of 400 barrels at the works, as a temporary supply till engines can be started. The greatest height to which the company force water is about 40 feet.

The South London or Vauxhall Company take their supply from the river Thames by a tunnel which is laid six feet below low water-mark, and as far into the river as the third arch of Vauxhall Bridge. At that particular place the bed of the river is described as being always clean, and without any of those depositions of mud and more offensive substances that are found in many other places. Besides the greater purity of the bed of the Thames there than where any of the companies on the south side take their supply, the company allow the water to settle in reservoirs. This company supplies about 10,000 houses with water at the rate of 1,000,000 gallons daily.

The Southwark water-works are the property of one individual. They are supplied from the middle of the Thames below Southwark and London Bridges; and the water thus taken is sent out to tenants without standing to settle, or without any filtration further than it receives from passing through grates of wire or small holes in metallic plates. The number of houses supplied from these works is about 7,000, and the daily supply of water about 720,000 gallons.

The supply in a tabular form is thus :—

Companies.	Houses.	Average per day.	Average per Year.	Average per House.
New River,	67,000	13,000,000	4,056,000,000	182
East London,	42,000	6,000,000	1,872,000,000	143
West Middlesex,	15,000	2,250,000	702,000,000	150
Chelsea,	12,400	1,760,000	549,120,000	142
Grand Junction,	7,700	2,800,000	873,600,000	365
Lambeth,	16,000	1,244,000	388,128,000	77
South London,	10,000	1,000,000	312,000,000	100
Southwark,	7,000	720,000	224,540,000	102

The three last companies, which all supply the south side of the river, will appear to have a far less average supply than the others on the north side. This arises from the difference in the size of the houses and the number of inhabitants. Thus the Grand Junction, which supplies the houses of rich districts, contributes near five times as much water per house as Lambeth, which is one of the poorest.

In consequence of the companies taking the water from the Thames within the limits to which the tide flows, it is necessarily, in the first instance, loaded with many impurities. The reports that were recently circulated relative to the deleterious quality of the water have been shewn to be very greatly exaggerated. The statement of Dr Bostock, given in the report of the commissioners, shews that by far the greater part of the impurities in the Thames water are mechanically suspended in, and not chemically combined with it; that they may be separated from it by filtration, or by merely allowing it to stand at rest. Most of the companies have recently made considerable efforts to improve their water; and though they may not have done as much as they might and ought to have done, a considerable improvement has been effected, and there is not the slightest foundation for the notion that the impurities of the water have ever been such as to affect in any degree the health of the inhabitants.

The beverage next to water in importance is the porter of London, a malt liquor much celebrated in every part of the world. Its flavour has been attributed to some peculiar properties in the water from which it is manufactured; but as some of it is made from Thames water, some from New River water, and some from natural springs within the premises of the brewers, that cannot be the cause. The breweries are generally very large establishments, with vessels of all kinds of most incredible capacity; and the malt as well as the liquor is conveyed from one part of the premises to another by machinery set in motion by steam power. The capitals invested in many of the large breweries are enormous; for not only do the cattle, drays, vessels, and premises employ much, but most of them have numerous public-houses either by purchase or on leases, and the occupants placed in them are bound to take the beer from the houses to which the premises belong. There are some persons keeping public-houses who brew their own beer, but their number does not much exceed twenty, and their operations are necessarily on a contracted scale. In 1831, the number of males above twenty years of age who are occupied in brewing appears by the parliamentary returns to have been 563; but this is a very indeterminate mode of viewing the extent of the trade.

Before the alteration of the law by which the tax on beer was taken off, the books of the excise office afforded exact accounts of the quantities of beer annually brewed, but now it is difficult to collect any facts with accuracy. In the year 1830, the quantity brewed, in barrels of thirty-six gallons, the last of those in which the tax was collected by the ten principal houses in London, was as follows :—

	Barrels.
Barclay & Co.	243,546
Truman, Hanbury, & Co.	178,318
Whitbread & Co.	155,761
Reid & Co.	151,566
Coombe & Co.	104,349
Henry Meux & Co.	83,422
Calvert & Co.	74,418
Taylor & Co.	63,658
Hoane & Co.	59,641
Elliott & Co.	42,827

These supply the chief consumption, the others, though numerous, not producing more than one-fifth of the great houses.

Insurance offices.

One class of public establishments of the most beneficial nature to trade especially, but in a greater or less degree to all other persons, consists of the various Insurance offices in London. These may be divided into three sections, viz. 1st, insurances on property at sea against all risks; 2d, insurances of houses and other goods against losses by fire; and, 3d, insurances on lives.

Marine insurances are chiefly effected at Lloyd's coffee-house, which has been already noticed under the head of Royal Exchange; but there are four joint stock companies who insure against sea risks to a large extent, and who for some descriptions of business are preferred to the underwriters at Lloyd's. Two of these are of ancient establishment, viz. the London Assurance Company, and the Royal Exchange Company. Two others are of more recent foundation, one called the Alliance Marine Assurance Company, and the other the Indemnity Mutual Marine Assurance Company. All of these are of indisputable credit and high honour, and transact a vast deal of business. Besides these there are clubs or associations formed by ship-owners, who agree, each entering his ships for a certain sum, to divide amongst themselves each other's losses. The more public institutions act in some measure in concert with the great mass of underwriters who carry on their operations at large, so far as to contribute to the expense of collecting information respecting the condition and equipment of all shipping in every port, and defraying the general expenses of the committee of Lloyd's.

The business of insuring against fire, and the premiums on the different descriptions of risks, are so well known, that any enumeration of them here seems unnecessary. The offices existing in London, and the amount they have paid for stamps in one year, viz. 1832, are as follow :—

Albion,	£15,011
Alliance,	20,147
Atlas,	21,010
British,	15,644
County,	48,507
Globe,	27,198
Carry forward,	£147,517

Brought forward,	£147,517
Guardian,	31,528
Hand-in-Hand,	10,960
Imperial,	28,234
London,	8,125
Phœnix,	75,076
Protector,	59,182
Royal Exchange,	54,824
Sun,	124,127
Westminster,	15,315
	£554,988

Each of these companies maintain fire-engines and a company of firemen, who, as soon as an alarm is given, hasten to the spot where a fire has broken out, and lend their assistance to extinguish it, and to aid the inhabitants in removing or saving their property. On such occasions they are also found of great service to check the depredations of thieves, who commonly congregate wherever a fire happens.

This business of insurance against fire has led to the establishment of county offices for the purpose in most parts of England; but except that at Norwich, which has a branch in London, and one at Exeter, they do but little business. The stamps of all the others scarcely amount to £100,000.

The business of Life Insurance is one almost exclusively known in England, and chiefly carried on in London; and no other country has adopted the system which has been so successfully pursued by us. The first society of the kind in England was the Amicable, established in 1706. The Royal Exchange and the London Assurance companies began to insure on lives in the latter part of the reign of George I., after which several projects of the kind were started and failed. In the year 1763, the Equitable was first established. This subject engaged the attention of Dr Richard Price, an eminent mathematician, whose judicious suggestions caused that society to obtain a high degree of success, and encouraged others, on his principles, to start the various companies which now exist in the metropolis. The greatest business of all these companies consists in receiving a sum by annual payments, according to the age of the life insured, on condition to pay at the death a given sum. The annual sum is greater or less as the person is younger or older, and regulated by tables of the expectation of life, framed from the most accurate views that have been obtained of the average mass of human mortality. The tables used by most of the companies are those of Carlisle and Northampton, calculated on the proportion of deaths in a given number of persons. Some of these tables having been thought uncertain or erroneous, the government has employed Mr Finlayson, and the companies Mr Milne and other calculators, to render them more perfect, and much assistance has been received from the facts relating to births and deaths by the population reports of Mr Rickman.

Life insurances are effected by different companies on various principles. One class receives a fixed annual premium, and pays a fixed sum when death occurs, and the proprietors themselves receive whatever benefits may accrue. The Pelican belongs to this class. Others divide the whole of the profits equally between the assured, though they may be divided into two sections, such as the Amicable, which distributes the profits among all the assured; whilst the Equitable allows none to participate in the profits, except such as are assured for the whole term of their lives. The third class have a body of proprietors distinct from the assured, and the profit is shared between the two bodies in various proportions, and in various modes. Thus the Crown Company divides two-thirds of the profits amongst the insurers for life. The Economic divides three-fourths of the profits amongst the assured. The Atlas gives the whole, by a septennial division, to those insured above L.100 for the whole of life. The Rock allots to the assured two-thirds of the benefit, and adds one-third to the capital of the proprietors. The others, viz. the Alliance, the Imperial, the Norwich Union, the Atlas, the European, the Guardian, the Hope, the Globe, the Law Life, and the Medical and Clerical, divide the whole profits, but differ much in their various times and manners of applying such profits.

The houses of several of the insurance companies are a great ornament to the streets where they have been erected. The finest of them are the County and Provident, in Regent Street; the Equitable, in New Bridge Street; the Union, in Cornhill; the Globe, in Cornhill; the Albion, in New Bridge Street; the British, in the Strand; the London and the Pelican, in Lombard Street.

Bridges.

The prosperity of London has been much advanced by the Bridges built over the river Thames, and by the facilities of intercourse with the districts to the south of it being thereby facilitated. In ancient times the connexion with those districts was maintained by means of ferries, the property of which belonged to individuals or to societies. Some of these were adapted for foot-passengers, and others for horses, or for other cattle; and the access by the roads leading to the ferries was such as to forbid the general use of wheel-carriages, so that even heavy goods were brought by pack-horses. The land on both sides was of a marshy nature, and the cost of constructing roads was one amongst many obstacles to the erection of bridges. With regard to the six bridges now on the Thames, none of them has any connexion with ancient recollections except London Bridge, to which the first notice will be directed, and then attention will be given to the others, according to the dates of their construction.

London Bridge.

At what period a bridge was built across the Thames, at the spot now occupied by one, cannot be settled. It could not have been before the year 993, when the Danish invader Unlaf sailed up the river as high as Staines; nor later than the year 1016, when Canute the Dane, in besieging London, was impeded in his operations by a fortified bridge, which compelled him to cut a canal on the south side of the river from Rotherhithe to a spot to the west of the city, and thereby complete the investment. The remains of this great work were found in 1694, at the place called Dock-head.

Howe the historian, represents that construction as the work of the monks of St Mary Overy, who not only built the bridge, but kept it in repair. But however that may be, it was built of wood, and was burned in 1136. It was then rebuilt of stone, and commenced in 1176, and it occupied thirty-three years to complete it, having been finished in 1209.

This great work was founded on enormous piles, driven as closely as possible together, and on their tops were laid planks nine inches thick, strongly bolted, on which the base of each pier was placed. Around all were the sterlings to protect the foundation, which so contracted the passage of the water as to form a fall of five feet with the ebb-tide, which caused the loss of thousands of lives between its erection and removal. The length of this vast work was 915 feet, and it had 19 arches of unequal dimensions, and greatly deformed by the sterlings, and by the houses on each side, which overhung it in a most terrific manner. In most places they hid the arches, and nothing appeared but the rude piers. It was narrow, darksome, and dangerous to passengers from the multitude of carriages; arches of strong timber frequently crossed the street, from the tops of the houses, to keep them together, and to prevent them from falling into the river. The houses had shops mostly tenanted by pin and needle makers. According to Fuller, the first needles were made by a Spanish negro in Cheapside, who died without communicating his art; but one Crouse, a German, in the reign of Elizabeth, first taught the English to make them.

ndon. In one part of the building was a drawbridge, which was protected by a strong tower, that served to admit ships, and served on several occasions as a means of defence. On the top of this tower was constantly presented the horrid spectacle of the heads of persons condemned for treason.

The new bridge, which was begun in June 1824, and completed in 1831, is about 200 feet higher up the river than that which it replaced. It is a fine object, projected by the late Mr Rennie, and executed by his sons. It is built of Scotch and Derbyshire granite, and is composed of five elliptical arches, the central one being the finest ever erected. On either side of the ends of the bridge are five flights of steps reaching to the water. The foundation of the whole is laid on piers, which were driven down twenty feet into the stiff blue clay forming the bed of the river, and on their tops are horizontal sleepers, on which the first course of masonry was placed. The whole length of the bridge is 928 feet, the breadth of the water-way 692 feet, the width from the outside of one parapet to that of the other 56 feet, the span of the centre arch 152 feet, that of the arches on each side of it 140 feet, the height above low water-mark 55 feet, and the width of the carriage-way 33½ feet. It is a proud monument of the present age. The money expended in building the bridge amounted to L.542,000, but to this must be added the cost of the approaches, consisting partly of old buildings, and partly of ground, so that the whole cost amounted to L.711,000. Much of this sum has been borrowed upon the security of the estates of the corporation.

min Bridg That noble structure, as it was then denominated, called Westminster Bridge, was begun in January 1739. The first stone was laid by Henry Earl of Pembroke, of whom Walpole reports, that no nobleman had a purer taste in architecture. The design was made by M. Labelye, a native of France. The work was not completed till November 1748, having thus occupied eight years and nine months. The expense of its erection was L.389,500. It is built wholly of Portland stone. The difficulties in the foundation were great, and were only surmounted by L.40,000 being expended on materials for that part of the work. The length is 1223, the breadth 44, and the foot-path 7 feet. It consists of thirteen large and two small arches, the centre one of which is 76 feet wide, and the others decrease 4 feet each as they proceed towards the two end arches, which are no more than 52 feet. On each side is a stone balustrade 6 feet 9 inches in height, with arched recesses for shelter from the rain; the height of this has been a subject of censure, because it obstructs a clear view of the noble expanse of water, and of the fine objects, especially to the east, which are scattered with no unsparing hand. The tide has been known to rise at this bridge 22 feet, much to the annoyance of the inhabitants of the lower parts of Westminster, for at such times their cellars are filled with water, and the floor of Westminster Hall so covered with it, that the judges and others require boats to bring them out, or wait until the ebbing of the tide lower the water.

ge. Blackfriars' Bridge fills up the space which was once the filthy mouth of Fleet ditch, and formed a continuation of the river Fleet from Holborn Bridge, but which was a broad flat surface filled with mud, on which coal barges rested when the tide was out, but floated at the time of high-water. It was commenced in October 1760, and finished in the same month of the year 1768. The plan was furnished by Robert Mylne, a Scotch architect, and the expense of the construction was L.152,840 : 3 : 10. The corporation of London advanced the money, and were to be repaid by a daily toll, which, after some years, became only a Sunday toll, and a few years later was altogether given up. The corporation, in a political fit, resolved that it should be called after the name of William Pitt, Earl of Chatham, then a favourite statesman with that body; but that name has never been adopted, except on the brass-plate below the foundation. The small square, however, which adjoins the bridge, bears the name of Chatham Place. The bridge is composed of nine elliptical arches, the centre one of which is 100 feet wide. The whole length is 995, the breadth of the carriage-way is 28 feet, and that of the footway 7 feet. Over each pier is a recess, supported by elegant Ionic pillars, and at each extremity are handsome flights of steps leading to the water, where boats are at all times in attendance. It is just half-way between the two more recently-erected bridges called Waterloo and Southwark, and has a fine view of both, as well as of St Paul's cathedral, and many other interesting objects.

London.

Waterloo Bridge. A bridge across the Thames between those of Westminster and Blackfriars had been long a desideratum, but no effort was made to erect one before the year 1806, when Mr Dodd, an architect, formed a party, who obtained an act of Parliament, and smoothed some of the obstacles which had impeded the progress of such an undertaking. But the committee and Dodd having disagreed, the work devolved on that eminent architect the late Mr Rennie, who lived to complete this most noble of all the structures of the British metropolis. The work commenced in 1811, when the foundation was laid, by driving into the ground at the bottom of the river, the piles upon which the several piers rest. Each of those piers have under them 320 piles of 20 feet in length, and 13 inches diameter, which are driven down, being one in every square yard. The bridge is built partly of Cornish, and partly of Aberdeen granite. The arches are elliptical, and all of the same size, and the road is consequently without any elevation or depression on passing it. The roads upon both sides leading to it have been raised so as to maintain a complete level to and over it. The style of the building is plain yet noble. It consists of nine arches equal in span, being 120 feet. The whole of the road from the Strand, where its ascent begins, to the Surrey side, which has been raised on forty brick arches, is 2890 feet. The length of the stone-work within the abutments is 1242 feet. The width of the bridge within the balustrades is 42 feet, that of the pavement or footway is 7 feet. The clear water-way under the nine equal arches is 1080 feet. At each extremity of the bridge are handsome flights of steps leading to the water.

This structure was erected in five years, and first opened on the 18th of June 1817, the anniversary of the victory of Waterloo, from which it receives its name. The ceremony was graced by the presence of the Prince Regent, afterwards George IV., the Duke of Wellington, and other distinguished personages. At the extremities of the bridge are toll-houses, of neat Doric structure, with turnstiles, which, by means of machinery below, indicate the number of persons that pass through, and thus act as a check on the collectors of the toll. The cost of this bridge, which was constructed by a joint-stock company, amounted to one million sterling, and it is to be regretted that the spirited society should be such pecuniary sufferers as they are at present. The chief hope of a better state of affairs, rests upon the expectation of a great increase of buildings on the Surrey side of the river.

Vauxhall Bridge. Vauxhall Bridge, the next in date, connects Chelsea with the parish of Lambeth. It was commenced in 1813, when the first stone was laid by Charles Duke of Brunswick, and finished in 1816, at an expense of L.150,000, which is to be discharged by the tolls over it, which are necessarily high. It is composed of nine arches of equal span, made of cast-iron, resting on piers formed by a wooden frame, faced with stone and Roman cement. The length is 860 feet. The arches are 78 feet in the span, and 29 feet in height. It was projected by Mr Dodd, who began it, and for a short time the conduct of the operation fell into the hands of Mr Walker, but it finally came under the direction of Mr Rennie, by whom the work was finished. The land upon the Middlesex side was very swampy, and it has cost much to make a good road to it. It forms a good communication with the western part of the town, and especially with the buildings erecting near Belgrave Square.

Southwark Bridge.

The latest of the bridges is that called, after the part to which it leads from Queen Street, in the city, the Southwark. It was projected by Mr Wyatt, but began to be constructed by Mr Rennie in 1814, with the aid of Mr Weston as sub-engineer. It was completed in 1819, having cost, including the expense of forming the avenues to it, L. 800,000. Messrs Joliff and Banks contracted to perform the work, and the cast-iron was supplied from the foundery of the Walkers at Rotheram.

This stupendous bridge consists of three cast-iron arches, resting on massive stone piers and abutments. The distance between the abutments is 708 feet. The extent of each abutment inclosed, including the land and the inverted arches, is 71 feet, formed of solid masonry. There are two piers, 60 feet high from the bed of the river to the top of the parapet, 24 feet in breadth between high and low water marks, and 75 feet long between one acme and another of the salient angles. The foundations of these piers are each about twelve feet below the bed or bottom of the river, and rest upon a platform of timber 2½ feet thick; these platforms repose on about 420 piles, most of which are driven 24 feet into the earth, making the depth, from the shoe of the piles to the parapet of the piers, 98 feet. The two side arches are 210 feet each in span, and the centre arch 240, with 43 feet clear opening above low-water mark at medium tides. The centre arch is thus the largest in the world, exceeding the admired bridge at Sunderland by 4 feet, and that of the once highly boasted Rialto of Venice by 167 feet. Many of the iron single or solid castings weigh ten tons each, and the total weight of iron in the bridge is 5308 tons. This bridge was constructed with so much accuracy, that, when the centerings of the middle arch were removed, it only sunk at the vertex one inch and seven-eighths. At the end of the bridge are turnstiles, with machinery to shew the number of passers through, similar to those of Waterloo Bridge. The tolls are lower than those of Waterloo for all but foot-passengers. They have not yet amounted to such a sum as the shareholders expected, or as they probably will become when all the avenues leading to it receive the improvements that are in contemplation.

Thames' Tunnel.

The attempted Tunnel under the Thames is so connected with the purpose for which bridges are constructed, that the two kinds of undertakings may be said to be in contact. Mr Brunel, the eminent mechanic and projector of public works, had formed a scheme for making a tunnel under the Thames, near Gravesend, which had failed; but the failure, instead of deterring him from other attempts, urged him on, by the conviction that it was practicable, and would be beneficial to the public. The confidence in his talents, assiduity, and integrity, was so great, that a company was speedily formed, and an act of Parliament was passed, incorporating it, for the specific purpose of the tunnel, in June 1824. The expense was estimated at L 160,000, which was soon subscribed.

The great merit of the invention for excavating with security, entitles it to a particular description. A general idea of the means proposed by this great engineer may be obtained by supposing a hollow box, of sufficient strength for its purpose, open to the rear, but closed on the front with moveable boards, and sufficiently large to contain one man at work. The front is placed against the face of the earth to be removed, and separates the workman from it. By means of the moveable boards, he can expose any part of the earth at his discretion. When he has removed one board, he excavates the earth which was behind it, to the depth directed, and places the board against the new vertical surface exposed; the board is then in advance of the box, and is kept in its place by props, which have their support in the rear. When he has thus proceeded with all the boards, it will be evident that an excavation will have been made equal to the area of the front of the box, and of a certain depth; and that the boards will be all in advance equal to this depth, and held there, disengaged from the box. The box is then pushed forward by screws to the boards, and the operation of excavation then recommences. The brick-work is immediately executed up to the box, and the security of the work is complete. When the area of excavation is proposed to be large, as in the case of this particular tunnel, a number of similar boxes is required. Their size is not increased, but they are arranged side by side to the width intended, and tier on tier to the height proposed. Those which are over each other are attached so as to be moved together in one vertical group, and have no connexion with the others on their sides. This whole assemblage is called the shield. In large excavations the whole shield is not moved forward at once; any one of the vertical groups may be advanced independently of any other, and the mode adopted is, to push on the alternate ones equally to a certain distance in front, and then to bring up and advance those left behind through the intervals of the first, and so on alternately.

Early in the year 1825 the shaft was begun which was necessary to be sunk on the Rotherhithe shore, in order to get down to the level of the intended works at that end of the tunnel. The sinking of this shaft, though the principle was well known to those employed in sinking wells, required a great degree of skill and intrepidity on the part of the engineer, owing to the magnitude of the operation.

A tower or cylinder of brick-work, 50 feet in diameter, 40 feet in height, and the walls of which were 3 feet in thickness, and resting on a circle of cast-iron, having its lower edges chisel-shaped, was built with the utmost care on the surface of the ground, and immediately over the situation of the intended shaft. In the upper part was suspended a steam-engine, of thirty-six horse power, for the purpose of draining and lifting the excavated earth to the surface.

This tower was begun on the 2d of March 1825, and, on the 1st of April, the excavation commenced within the inclosure. As the work proceeded, this vast structure, with its engine, descended without accident, and continued to do so for twenty days, through successive strata of gravel and other earths, until, at 37 feet from the surface, it rested upon a solid bed of clay. It was there permitted to remain, but the excavation was continued, and the cylinder under built to the depth of 24 feet. At this level the diameter was reduced to 25 feet, and another cylinder inserted, sunk 20 feet more. This lower part was intended as a tank or receptacle for drainage water; and suction pipes of the engine-pump were carried into it, for the purpose of carrying it off. The total height of this extraordinary shaft is 84 feet, 64 feet of which are of 50 feet diameter, and 20 of 25 feet. It consumed 260,000 bricks, and 1200 barrels of cement, and the weight of it is about 900 tons. It is intended eventually as the staircase for persons on foot. Near it, a little to the southward, a shaft is to be built, by which carriages are to ascend and descend, which will be 160 feet in diameter.

The soundings along the proposed line across the river give 12 feet water at low tide, and 36 at the highest, in the deepest parts; the bed of the river was found to be a stratum of sand, about 3 feet 8 inches thick, lying upon one of about half that thickness, composed of clay and sand, beneath which was a bed of tenacious clay. The descending order of the strata, at the lower part of this bed, in which the tunnel is executed, is as follows: Stiff blue clay about 2 feet; silt, 7 feet; silt, mixed with shells, 7 feet; indurated clay, 3 feet; silt and gravel stones, 3 feet. It was found that the whole length from shaft to shaft would be 1300 feet.

Early in December the first horizontal excavation commenced. At the bottom of the wider part of the shaft a shield of cast-iron, weighing 120 tons, 37 feet in width by 22 feet in height, and 8 feet in depth, with a complement of thirty-six men, each in his respective cell, was entered nto the solid earth, and began its new and extraordinary march. It proceeded for several months, at a rate of about wo feet in twenty-four hours, displacing from 90 to 100 tons of earth, which was lifted to the surface by the engine in the haft. In each foot 5500 bricks were used. On the 2d of March 1826, it had advanced 470 feet, or about one-third of he whole length; and, though the line of the tunnel dips about 3 feet in 100, the excavation in one part, towards the middle of the river, had approached within 10 feet of the water above it. The brick-work which followed immediately, illed exactly the aperture which was made by the shield, and contained in its mass two arched passages or roadways, each 13 feet 9 inches wide, and 16 feet 10 inches high, lying by the side of each other, with a wall of 3 feet inches between them. The passages at first have no conexion, but are subsequently laid together by arched erforations through the brick-work that separates them. The sides are three feet, and the arches at top and botom 2 feet 7 inches thick at their smallest parts. About 1,000 bricks per day were used, entirely laid in cement; nd the labour of one hundred men was constantly kept p by relays at stated periods. A main from a gas-work was laid along the floor, which conveyed the gas to columns laced in the connecting arches as they were formed, branches rom which illuminated both the roadways, and a total freeom from water was preserved by drains beneath, which mptied themselves into the engine-tank beneath in the haft. In the use of these, and innumerable other expeients to facilitate the progress, and anticipate or overcome he difficulties, of this extraordinary work, Mr Brunel dislayed such fertility of invention, depth of resource, and rofessional intrepidity, as must place him in the highest ank of professional engineers. But these qualities were estined to a very severe trial. On the 18th of May 1827, t a distance of 544 feet from the shaft, the river found its way through a portion of loose earth, and entered the tunnel, through the shield, with a velocity and volume that illed the tunnel and the shaft in fifteen minutes. This appened whilst the workmen were at their duties, but no ives were lost. About 1000 tons of loose soil and rubbish escended into the tunnel.

The breach was examined by means of the diving-bell, nd repaired by depositing about 1500 cubic yards of clay, n bags, in and around it. The water was then pumped out, nd the permanent works were found very slightly injured; he shield was restored and adjusted, and in the latter part f September the work was recommenced. The dangerus part was passed, and 52 feet added to the length beore achieved, when, on the 12th January 1828, the river roke through the shield a second time. The tunnel as filled in less than ten minutes, and the rush of water rought with it a current of air that put out the lights; nd, principally owing to this circumstance, six of the worken were unable to extricate themselves; the rest escapd. Mr Brunel reported that the aperture in the bed of he river was much less than at the former accident, and onsequently that the mischief might be repaired at much ss expense. The point at which this irruption occurred as at 600 feet from the shaft, within 25 feet of the middle f the channel of the river, leaving about 700 feet to be xecuted. The breach was, however, stopped, the water umped out, and the rubbish removed.

The funds of the company were now nearly exhausted.

Independently of the expense caused by this last accident, the expenditure up to that time had been L. 157,000, of which about L. 38,500 had been laid out in the purchase of premises and machinery, and L. 118,500 in the works. The directors, in their report, state that the sum of L.75,000 will be required to complete the Tunnel to the north embankment. As the public appeared to take a great interest in the completion of the work, it was resolved to try the effect of contributions; but though some individuals subscribed liberally, the amount was on the whole but small, and not more than sufficient to clear the works. It was then determined to open the tunnel to the inspection of the public, on paying one shilling for admission. But this has done little more than defray the expense of keeping the works and the machinery in good order.

Of late the government has been prevailed upon to grant the company a loan of exchequer bills, and the work is again proceeding; but the prospect of its completion is still obscure, owing more to the want of pecuniary power than to any doubt of the practicability of its final accomplishment.

Hospitals.

St Thomas's.

The Hospitals of London are numerous, and some of them very wealthy, especially those of royal foundation, which will here receive the first notice. *St Thomas's Hospital*, in the High Street of Southwark, was founded by the prior of Bermondsey in 1213, and surrendered to Henry VIII. in the year 1538. The corporation of London having purchased the manor of Southwark in the reign of Edward VI., are ex-officio governors; but others are elected as governors who subscribe L.50 to the institution. The building having become dilapidated by time, was taken down, and rebuilt by voluntary subscriptions in 1693, and then formed three squares, to which were added, in 1752, a new portion of considerable magnificence, which comprised several wards and various offices. It now consists of four quadrangular courts. In the first are the wards for females; in the second two chapels, with houses for the treasurer and other officers; the third court contains wards for the men; and the fourth, besides wards for men, has hot and cold baths, a surgery, the theatre, capable of containing 300 persons, in which lectures to the pupils are delivered, and the apothecary's dispensary.

There are in the institution 18 wards, with 485 beds. It is destined to receive the sick poor, and those maimed by accident. The former must be recommended by a governor, but the latter are received at any hour, without recommendation. The annual expenditure is about L. 10,000; and in some years 11,000 patients have received assistance either within the building, or at their own residences. This is one of the chief surgical schools of the metropolis. The medical officers being men of the greatest talents in the profession, naturally draw around them those who are solicitous to acquire skill and knowledge.

St Bartholomew's.

St Bartholomew's Hospital is near the church of St Bartholomew the Greater. It is in fact only the choir of an ancient conventual church, belonging to a priory of blackfriars, founded by one Ralière, who had been a minstrel or jester to King Henry I., whom, as the tradition goes, in a horrible dream, from which he was delivered by St Bartholomew's appearance, the saint warned to quit his profligate life, and found this religious house. To this person, however, who lived in the year 1102, have the inhabitants of London, during more than seven centuries, been indebted for one of the most beneficent of its public institutions.

The king made Ralière a present of a waste spot of ground, on which he built an hospital for a master, brethren and sisters, for the entertainment of the diseased poor, for women with child till they should be delivered, and for the support of such children whose mothers died in the house, till they obtained the age of seven years. It was placed under the management of the priory; and its revenues, by what means acquired does not appear, were found, at the dissolution of the priory, to amount to about L. 305 annually, a large sum at that day. By the liberality of numerous contributors, by benevolent legacies, and above all by the increased value of land, this institution has gone on increasing in wealth and utility. The present building was commenced in 1729. Although the ancient erections had escaped the great fire of 1666, yet they had become ruinous from age, when, by voluntary subscriptions, a sum to rebuild it wholly was collected. It is a noble pile, composed of four buildings, which form a large square, and are joined together by stone gateways. One of these piles contains a large hall for meetings of the governors, an accounting-house, and other offices; and the three other piles consist of apartments well arranged, in which are the patients. The principal gate is of the Doric order, consisting of a large arch placed between two pillars, supported by emblematic figures. The grand staircase, leading to the hall used by the governors, was gratuitously painted by Hogarth, and the subjects are the Good Samaritan and the Pool of Bethesda. The hall is deemed the finest apartment in London, its proportions being those of a double cube. Henry VIII. settled L. 500 per annum on the institution, and a full length portrait of him adorns the room, whilst the walls are covered with the names of the contributors, who, by donations of L. 50 and upwards, have been chosen governors. There is also a fine portrait of Dr Ratcliffe, who left L. 500 a-year for the improvement of the diet, and L. 100 a-year to purchase linen for the patients; and of Perceval Pott, the eminent surgeon, who was a great benefactor to the institution. In the window there is a portrait of Henry VIII. delivering the charter to the Lord Mayor, and Prince Arthur, with two noblemen holding white rods, standing near him. Attached to the south pile of the square is the dispensary, a stone building, in which medicines and dressings are prepared.

The physicians and surgeons of this establishment are the first for skill and talent in the kingdom; and this, with the numerous patients, makes it one of the best medical schools of the metropolis. The number of patients annually relieved generally exceed 10,000; and the expenditure of the institution, about equal to its income, is nearly L. 30,000 a-year.

Guy's. *Guy's Hospital*, in St Thomas's Street, Southwark, is perhaps the most extensive beneficent institution, that in modern ages has been founded by one individual. Thomas Guy was the son of an anabaptist lighterman and coal-dealer in the borough. Upon his death his widow removed to her native town of Tamworth, with her only child, and from thence at the proper age sent him to London, to be bound apprentice to a bookseller in Cheapside. When he had served his term, he commenced business for himself, with a capital of two hundred pounds. He connected himself with some others in an illegal trade in bibles, which were printed in Holland and smuggled into this country, to the great injury of those who enjoyed the exclusive right to deal in them. This was successfully carried on for some time; but it was abandoned by some prosecutions. Guy then prevailed on the University of Oxford to contract with him for their privilege of printing bibles. By this and other operations, accompanied with great economy, he was enabled to amass an early competence, and then he established some charitable institutions in Tamworth, where he had passed his early youth. By the sale of bibles, by buying up seamen's tickets in the latter part of the reign of Queen Anne, when they were at a great discount, and operations in South Sea stock in the reign of George I., he had acquired a vast fortune, without increasing in the same degree his personal expenses.

Guy had been a most extensive contributor, at an early period of his prosperity, to the hospital of St Thomas, in which he had been at the expense of adding to the former part three additional wards. At seventy-six years of age, he took from the governors of that hospital a piece of vacant ground adjoining, on lease for 999 years, for which he paid them L. 18,793, 16s., and began to build his hospital in 1721. At his death, which happened in 1724, he bequeathed to the institution the vast sum of L. 219,499.

The building is entered from an area, inclosed by handsome iron gates, in which is a statue of the founder. It consists of a centre and two wings, and behind the former a separate part for the reception of lunatics. One of the wings contains a hall and a room for business, and the other a chapel.

The hospital was originally established for 400 sick and diseased persons, and for 20 incurable lunatics. The average number now admitted is about 2250 patients, besides upwards of 20,000 out-patients. It has an admirable establishment of medical men of the highest rank in the several branches of the healing art, and is one of the best schools for students in medicine and surgery.

The governors are a corporate body, appointed from those of St Thomas's, in number sixty; and if there are not forty, the Lord Chancellor has the power to name as many as shall complete the number to fifty. A committee of twenty-one has the management of the interior, of whom seven are changed each year. There is attendance at the surgery constantly, and all accidental patients are instantly admitted.

A splendid bequest has been added to the previous resources of the institution, by the will of Mr Thomas Hunt, who, in 1829, left L. 200,000, on condition that adequate accommodation should be made for the admission of 100 additional patients.

Christ-church. *Christ-church Hospital*, near St Bartholomew's, is a royal foundation. It was originally the house of the Greyfriars, or mendicants of the order of St Francis, founded in 1225, by John Ewen, a mercer. The church was considered as the most superb of the conventual class, and was erected by the contributions of various devout and distinguished persons. The choir was added in 1306 by Margaret, second Queen to Edward I. Isabella, Queen to Edward II., gave three score and ten pounds of silver, and Queen Philippa, wife of Edward III., gave three score and two pounds, towards the building. John de Bretagne, Duke of Richmond, built the body of the church at a vast expense, and Robert de Clare, Earl of Gloucester, gave twenty great beams out of his forest of Tunbridge.

The reputation for sanctity which this order of friars had acquired was so great, that numbers of persons of the highest rank deemed their future state secure if they died in that order, and were interred within its walls. Multitudes, therefore, were crowded into this holy ground. Amongst others, no less than four queens are recorded, and many of the highest rank of the nobility, and members of the royal family. Many of those who suffered under the sentence of the law for atrocious or for state crimes were consigned to the holy precincts, in order to secure their eternal salvation.

At the suppression of the religious houses by Henry VIII., the fine church, after being despoiled of its ornaments for the king's use, was made a storehouse for French prizes, and the monuments were sold or destroyed; but Henry, from remorse or superstitious fear, granted the church to the city, and directed it to be opened for divine service.

The conventual building remained in a dilapidated state till the latter end of the reign of Edward VI. The story told is, that the amiable young prince was so deeply impressed by a sermon which he heard from Bishop Ridley, that he resolved to found three great hospitals in the city. These were, St Thomas's, in the borough of Southwark, for the sick or wounded poor; Bridewell, for the thriftless; and

Christchurch, for orphans and other poor children, to be aken care of, and apprenticed at proper ages to different rades.

At first this institution was upon a contracted scale, but eing gradually enlarged, it consists of common schools for oys and girls. Charles II. joined to it a mathematical school, nd charged the Exchequer with an annuity of L.1000 for s support; and a private individual, named Travers, inreased the capacity for that kind of study. The corporaion of London are governors, but any individual contriuting L.400 is elected to that rank. The pupils are noinated by the governors in their turn as vacancies occur; ut the aldermen of London have one annual nomination ach. The greater part of the children admitted are those f freemen of London, or of clergymen of the established hurch. A branch of this institution is maintained at Hertord. The total number of children is about 1100. The ducation is well conducted, and, as there are funds approriated for that purpose, those who excel in classical learng have good exhibitions at the university. The matheatical boys are fitted for the navy or other professions; nd many very distinguished men have received their eduation here. The buildings are old and irregular; but of te years have received great improvements, and latterly n opening has been made into Newgate Street, shewing e front of the new hall, in the architecture of the Tudor ge. In the hall is a fine picture of Edward, the founder, y Hans Holbein. The pupils are well fed, and warmy, though coarsely clothed, and carefully attended when ck. The masters are generally men of great merit. The hole expenditure of the establishment amounts to about .30,000.

Bethlehem or Bedlam Hospital. Although this instituon has been recently removed to a more convenient situaon, yet some notice of the origin and history of an estalishment that has generally engaged the attention of all ersons who have either a permanent or a temporary conection with London, cannot be unnecessary here.

The ancient building of St Mary of Bethlehem was foundd by Simon Fitzmary, sheriff of London, in 1247. It consted of a prior and canons, brethren and sisters, and proably stood in St Martin's in the Fields, but was removed rom thence at the instance of one of our kings, who was nnoyed at the presence of lunatics, for whom it was foundd, being so near his own residence. It was therefore reoved to Bethlehem without Bishopsgate. In 1545, the ity was presented with the hospital, and under their direcon it continued till it was found too small for the numer of unfortunate beings that sought relief. In 1675, the ord Mayor and Aldermen removed the hospital to the uth end of Moorfields, and, at an expense of L.16,000, rected a magnificent pile of buildings. It was designed ter the plan of the palace of the Tuilleries in Paris. ouis XIV. was so incensed that his palace should be made e model for a lunatic hospital, that it was said he ordered most whimsical and not very decent revenge. This buildg was 540 feet in length, with a gallery from one end to e other, out of which were the doors to the ranges of apartents for the patients on both sides of it. Two large wings ere added to the building in 1734, which enabled it to adit 250 patients. Being in a decayed state, it was resolved remove the whole institution to a more airy spot. The ew hospital was begun in St George's Fields in 1812, and nished in 1814, at the cost of L.100,000. It has a magnicent front 580 feet in length; the centre is surmounted y a dome, and ornamented with an Ionic portico of six olumns, supporting the arms of the United Kingdom. The terior is well arranged, and capable of receiving 200 paents. In the hall are two fine figures representing raving d melancholy madness, which were formerly on pedesals before Old Bedlam, and have always excited the greatest admiration. The annual income and expenditure of this institution is about L.18,000.

An account of the number of Patients admitted into Bethlehem Hospital in the years from 1820 *to* 1832, *both years inclusive.*

	Males.	Females.
Curables admitted, . . .	1047	1534
Incurables, ...	29	51
Criminals admitted, . .	37	24
	1113	1609
Cured, ...	242	461
Died, ...	90	86

Of those cured, four males and sixteen females were of the class deemed incurable; and of those who died, seventeen males and twenty-four females were of that class.

Bridewell.

Bridewell is in Bridge Street, Blackfriars, which, as well as the church and the parish in which it stands, received the name from a holy well dedicated to St Bridget or Bride. It was formed in part out of the remains of an ancient castle, which stood near the river Fleet. Many of the materials, in the reign of William the Conqueror, and in that of Henry I., were applied to reconstruct St Paul's cathedral. It subsequently became the residence of several of our monarchs; and Henry VIII. fitted it up for the reception of the Emperor Charles V., upon occasion of his visit to England in the year 1522. The emperor, however, preferred the Abbey of Blackfriars for his own residence, but his retinue was lodged at Bridewell, and both were connected by a gallery over Fleet-ditch, and a passage cut through the city wall. Henry himself took up his abode in Bridewell in 1529, whilst the question of the validity of his marriage was under discussion in the hall of Blackfriars.

It was neglected and had fallen into a state of decay, when Bishop Ridley requested it of Edward VI. for a charitable purpose. It thus came into the hands of the city, who have used it as a house of correction for disorderly persons, idle apprentices, and vagrants; and of late years eight or nine hundred persons have been annually consigned to it for punishment or amendment. The buildings consist of a quadrangle, on one side of which is an extensive hall, representing the founder and some of the benefactors; whilst the other sides are occupied by the prisoners. Another house connected with the institution has been recently erected in St George's Fields.

The Church of St Bride's, near to this building, was erected by Sir Christopher Wren, and is distinguished by the beauty of its spire. The interior is imposing. It has a clock illuminated at night; and it has been in some measure opened to the public view, by purchasing the ruins of some houses which had been burned down in Fleet Street.

Besides those of royal foundation, the following are the most considerable hospitals that depend on donations already received, or on annual subscribers, or on presents at admission to the government.

St George's.

St George's Hospital, at Hyde Park Corner, was opened in 1733 for the reception of sick and lame patients; but as the building was too confined, it was begun to be taken down in 1828, and to be gradually rebuilt on a much larger scale. Contributions for the purpose have flowed in with great liberality. The magnificent structure, which is an ornament to the entrance of London, has been completed, and now about 350 beds are set up to receive patients; whilst the poor are supplied with medicines without being received into the house when the beds are full.

Middlesex.

The *Middlesex Hospital*, in Charles Street, Cavendish Square, was founded in 1745, for the relief of sick and lame patients, for the reception or attendance at their own homes of lying-in married women, and for supplying the indigent sick with advice, medicine, diet, and lodging. There was afterwards added, by the liberality of the late Mr Whitbread, a department for patients afflicted with cancer, who are admitted to remain during their lifetime. The hospital is capable of receiving 300 patients; but many are attended at their homes, and supplied with medicines, under the superintendence of three physicians, an accoucheur, and three surgeons. It is under the management of a patron, a president, fourteen vice-presidents, and a committee of the governors, who are such persons as contribute three guineas annually to the establishment.

The London.

The *London Hospital* is a vast pile of building in Whitechapel Road, to which spot it was removed, when it obtained a charter, in 1759. It had before existed in Prescot Street, Goodman's Fields, since 1740. The patients received here are chiefly sick and wounded seamen, watermen, coal-heavers, ship-wrights, rope-makers, and labourers in the dockyards and on the quays. It is a subject of regret that this hospital, situated in a district where more relief is required for the sick and diseased than perhaps in any other division of the metropolis, should be so deficient in resources to be unable to occupy the whole of the building with patients, though zealous attempts have not been wanting to obtain the disposal of more ample funds.

St Luke's.

St Luke's Hospital, in Old Street Road, was originally instituted at a place called Windmill Hill, near Moorfields, in 1732, and removed to the present spot in 1751, but not completed till 1786. It is destined for the reception of such lunatics as are deemed incurable, as well as for those of whom some hope is entertained. It is a solid large edifice, nearly 500 feet in length, consisting of three stories besides the basement, and with attics at the extremities; and the whole has an imposing effect. The interior contains apartments for the medical and the other officers, and accommodation for 300 patients, of whom 100 are on the incurable list.

The annual income of the hospital is about L.9000. Persons paying twenty guineas at once, or paying seven guineas, and agreeing to pay three pounds eighteen shillings in the four succeeding years, are admitted to become governors.

Charitable institutions.

The charitable institutions of London and the adjacent villages are so numerous, that they will not admit of minute accounts being given of the whole of them. Some of the most distinguished for their magnitude, their antiquity, or their utility, have been already noticed, and the remainder can only be enumerated, with the date of their origin, their locality, and the purposes to which they are applied.

Institutions for Medical and Surgical Relief generally.

Westminster Hospital, founded in 1719, in James Street, Buckingham Gate, now rebuilding on a larger scale.

Charing Cross Hospital, in King William Street, founded in 1831, and recently opened to patients.

Hospital of Surgery, in Panton Square, St James's, founded in 1827.

Royal Metropolitan Infirmary for Sick Children, in Broad Street, Golden Square, opened in 1830.

Royal Universal Infirmary for Children, in Waterloo-Bridge Road, founded in 1816.

Seamen's Hospital on board the ship Grampus, founded in 1821, having an office in Bishopsgate Street Within.

French Hospital for Protestant Refugees, in Luke Street, Old Street, founded in 1716.

Asylum for the Recovery of Health for Persons in Narrow Circumstances, who, by paying a small sum weekly, are accommodated better than they can be in hospitals or in private houses, founded in 1820, at Leisson Grove, Marylebone.

Jews' Hospital for the Support of Aged and Sick, in Mile-End Road, founded in 1797, by voluntary subscriptions.

Institutions for Particular Complaints.

Hospital for Casual Small-Pox and for Vaccination, in Pancras Road, Gray's Inn Lane, founded in 1746.

London Fever Hospital, in Pancras Road, founded in 1820.

Lock Hospital for the Cure of Venereal Complaints, at Grosvenor Place, Hyde-Park Corner, founded in 1746.

Asylum for the Deaf and Dumb Poor Children, a large building, with means of receiving 200 children, and teaching them some handicraft trades, in the Kent Road, and was founded in 1792.

London General Institution for the Gratuitous Cure of Malignant Diseases in Greville Street, founded in 1820.

Institution for the Cure and Relief of Glandular and Cancerous Complaints, founded in 1820, in Nelson Square.

Royal Infirmary for Diseases of the Eye, founded in 1804, in Cork Street, Burlington Gardens.

Institution for the Gratuitous Cure of Cataract, in Windmill Street, founded in 1819.

London Ophthalmic Infirmary, founded in Moorfields in 1805.

Kent and Surrey Eye Infirmary, in Dean Street, Southwark.

Surrey and Southwark Infirmary for Curing Diseases of the Eye and Ear, founded in 1828.

Royal Westminster Infirmary for Diseases of the Eye, founded in 1828, in Marylebone Street, Piccadilly.

Royal Infirmary for Diseases of the Ear, in Dean Street, Soho, founded in 1816.

City of London Truss Society, in Queen Street, Cheapside, founded in 1807.

Rupture Society, Golden Square, founded in 1805.

Southwark Truss Society, in High Street, Southwark, founded in 1811.

London and Westminster Infirmary for Cutaneous Diseases, Great Marlborough Street, founded in 1819.

Asylum for the Cure of Scrofula and Cancer, on the Terrace, Bayswater, founded in 1822.

Infirmary for Asthma, Consumption, and Diseases of the Lungs, Union Street, Bishopsgate.

National Vaccine Establishment, Percy Street.

Vaccine Pock Institution, Broad Street, Golden Square, founded in 1799.

London Vaccine Institution, in Union Court, Holborn, founded in 1800.

Royal Jennerian Society, in Beer Street, near the Tower.

Lying-In Hospitals, Infirmaries, and Charities.

Queen Charlotte's Lying-in Hospital, Manor-House, Leisson Grove, founded in 1752.

City of London Lying-in Hospital for Pregnant Married Women, in the City-Road, founded in 1750.

British Lying-in Hospital for Married Women, in Brownlow Street, founded in 1742.

General Lying-in Hospital, in York-Road, Lambeth, founded in 1755.

Westminster Lying-in Hospital, in Queen's Square, founded in 1801.

Royal West London Infirmary and Lying-in Institution, Villars Street, Strand, founded in 1818.

Royal Maternity Charity for Delivering Poor Married Women at their own Houses, in Knight Rider Street, founded in 1757.

Ladies' Benevolent Society for the Relief of Poor Lying-in Women, in Salisbury Street, founded in 1813.

United Institution of London and Westminster for the Relief and Delivery of Indigent Women, and for the Treatment of Diseases incident to Children, in Warwick Street, Golden Square, and Philip Lane, London Wall, founded in 1822.

The City of London Lying-in Institution for Providing Medicines and Nurses to Poor Married Women in their own Houses, founded in 1811, in Swan Alley, Colman Street.

Endeavour Lying-in Charity for Delivering Poor Women, and Lending Clothes, in Norton Street, founded in 1794.

Ladies' Lying-in Charity for St Andrew's, Holborn.

New Court Benevolent Society for Relieving Married Women during their Confinement, in New Court, Carey Street, founded in 1814.

Finsbury Midwifery Institution, in St John's Street, Clerkenwell, founded in 1823.

The Ladies' Benevolent Society for Relieving and Clothing Jewish Married Lying-in Women at their own Houses, in Artillery Place, founded in 1812.

To the list of charities connected with the circumstances of disease, might be added the names and situations of twenty-seven dispensaries. These are to be found in every district of the metropolis, and in them constant attendance is given to the cases of the diseased, who are recommended by governors. Advice and medicines are afforded gratis at the houses, and the sick unable to attend are visited by the professional men at their own homes. It deserves to be noticed, to the credit of the liberality of the gentlemen of the medical profession, that in all of those charities the aid of physicians and surgeons of the greatest skill is gratuitously afforded.

Besides those charitable associations in behalf of lying-in women, which appear ostensibly, there are in every quarter small societies of from ten to twenty ladies, who furnish the necessary clothing and food, within their respective circles, to indigent females, whilst waiting for, or recovering from, their confinement. The benevolence of the inhabitants of London, proved by the numerous institutions for the relief of the diseased, has had a beneficial effect on the health of the whole of the population of the kingdom. It has produced one of the best schools of the healing art, because one in which the greatest number and variety of cases may be attentively examined, and where instructions arising from actual practice may be most advantageously acquired.

Schools of anatomy were first opened in London about the year 1720, and have been extending ever since; and now every hospital has become a school, at which not only anatomy, but every branch of medical or surgical knowledge, may be acquired. Lectures are delivered by men of the first eminence, during the winter months, and practice, especially in the hospitals, is admirably combined with theory. By a late law, greater facility has been given to the study of anatomy, by the greater facility of obtaining subjects for dissection than was formerly enjoyed.

The more public establishments for the promotion of the art of healing may be here noticed.

College of Physicians.

The College of Physicians stood originally in Knight Rider Street, then in Amen Corner, and at length in Warwick Lane, near to Newgate. It was founded by a Dr Linacre, who first rescued the medical art from the hands of illiterate monks and empirics. He had studied in Italy, and had been successively physician to Henry VII. and VIII., and Edward VI., in whose reign he died, in 1524. He was the first president of the college, and was succeeded by Dr Caius, the founder of the college of that name in Cambridge.

As the building in Warwick Lane had become injured by time, it was resolved to build a new and more appropriate pile, in a more favourable spot. Pall-Mall East has been selected, and its eastern side forms a most imposing part of the new square, in which the image of Charles I. stands. It was designed by that eminent artist Smirke, and the valuable materials of the ancient house were removed to it in 1823. The portico, of six Ionic columns, leads to a noble hall, the roof of which is supported by fluted Doric pillars, each consisting of a single block of stone. On the left is a dining-room, in which are numerous portraits, particularly those of Henry VIII., Cardinal Wolsey, and Sir Hans Sloane. A handsome staircase leads up to the library, which is surrounded with a gallery, and contains a valuable collection of books, and some anatomical preparations, and also portraits of Drs Harvey and Ratcliffe, with a bust of King George IV., by Chantrey. The examiners' room has several portraits, as well as busts of Drs Baillie, Mead, and Sydenham. There is also a small but neat theatre, a reading-room, and other apartments.

The college is constituted in a president, elects, and fellows, who license all physicians who practise in the bills of mortality, and grant extra licenses to those who practise in the rest of the kingdom. The fellows can only be appointed by such as have graduated at Oxford or Cambridge.

College of Surgeons.

The Royal College of Surgeons was assembled for many years in the Old Bailey, near the Sessions-House, and the bodies of those criminals were carried to it for dissection, who by the law were subject to that operation. It has been now removed to Lincoln's Inn Fields, to a structure erected for the use of the college.

This was one of the old city guilds or companies connected with that of the barbers till the reign of Henry VIII., when they obtained a separate charter. Since that time various and important regulations have been obtained to increase its utility and respectability. The duty of examining medical officers for the navy and army, and for the East India service, has devolved on them, and without their examination no person is allowed to practise surgery in London or Westminster, or in a circuit of seven miles round the hall.

The hall is a noble building of the Ionic order, with a handsome portico, over which is inscribed, *Collegium regale chirurgorum*, and above that are the arms of the college, supported by the two sons of Æsculapius. The interior is grand and appropriate, containing a theatre in which lectures are delivered on anatomy and other subjects connected with the profession, which are illustrated by the collection in the rich museum, and especially the invaluable preparations of the late John Hunter, purchased by order of the government. In these is exposed to view the gradations of nature from the most simple state in which life is found to exist up to the most perfect and most complex of the animal creation, man. There is also a rare collection of objects of natural history, with specimens of vegetable and fossil productions. There is also a most valuable library, and admission to every part is to be obtained from any member of the company.

The apothecaries of London were formerly incorporated with the company of grocers; but in 1617 a separate charter was granted to them, which enabled them to regulate the sale of drugs and medicines, and to sell them for gain. This is now a trading company. They have a house and large old premises in Water Lane, near Blackfriars Bridge, where they sell drugs and chemical preparations, and such is the accuracy with which the latter are prepared, that many practitioners administer none but what is obtained from their laboratory. The whole of the medicines for the navy and the army are compounded and supplied from their manufactory or stores. Prescriptions for private persons are also made up by them. The Physic Garden at Chelsea is under the direction of this company, having been bequeathed to them by Sir Hans Sloane, on condition that they should present annually to the Royal Society fifty new plants till the number should amount to 2000. This condition has been punctually fulfilled, and the specimens are preserved in the collection of that society. A general herbarizing tour is made yearly by the members of the company for the improvement of students and apprentices. By some legislative enactments several powers have been conferred on the company. No person is now allowed to practise in any part of England or Wales, without having first obtained a certificate of his qualification from the court of examiners of this company. As a trading concern it is profitable, and the directors, besides giving very sumptuous entertainments, divide a good yearly sum amongst its members.

Independent societies.

There are a variety of independent societies established in London, which are voluntary associations, and not incorporated bodies. One of the first of these is in Bolt Court, Fleet Street, and was opened in 1773 at Crane Court, by an introductory lecture delivered by Dr Lettsom. There is a library, consisting of more than 30,000 volumes; and the object of the society is to receive medical papers, and useful facts, respecting difficult and extraordinary cases, to increase exertion by bestowing honorary rewards, and to preserve and increase their collection of medical books.

Another and similar association was established in Lincolns-Inn-Fields in 1805. It has an extensive library, and ranks amongst its members some of the most eminent members of the faculty in the metropolis.

Lectures on anatomy, physiology, medicine, obstetrics, and chemistry, are delivered at stated times at the various hospitals, at the London University, and at King's College, by the most celebrated men in the profession. Others are delivered at theatres of anatomy in Great Windmill Street, at Mr Tanton's in Hatton Garden, at a theatre in Webb Street, Maze Pond, in the borough, and by many medical men at their own houses. These lectures are sometimes advertised in the newspapers, but more commonly made known by the medical booksellers. The terms vary from two to five guineas for the first course, but to those who attend more than one, the rate is subsequently lowered, as well as for an annual or perpetual ticket of admission. These lectures are commonly given in the autumn or the winter.

The Royal Humane Society may not improperly be noticed in connexion with medical societies. The object is to restore persons apparently drowned. It was founded in 1774, and has a permanent house in Chatham Place. It has been so far of use that more than five thousand persons have been rescued from death, after their lives appeared to have terminated; and by its example forty-five other similar associations have been formed in different parts of the kingdom. The Society offers rewards to persons who, within a certain time after the accident, rescue drowned people from the water, and convey them to places where means for their recovery can be applied, and also gives medals to those who have exerted themselves to save persons from death by water. It has eighteen receiving houses in and about London, the principal of which is in Hyde Park, near the Serpentine River. In them every thing necessary for the resuscitating process is kept in a state of constant readiness, and attendance can be immediately obtained.

A Veterinary College was established at Camden Town in the year 1791, for promoting the knowledge of farriery, under a president and twenty-four directors. There is a professor, and, upon an average, about thirty pupils. The buildings are extensive, and appropriate lectures are delivered, and dissections performed, whilst an infirmary for horses has been established.

In looking at the edifices in London dedicated to religious purposes, it is impossible, from their great number, that the great majority can receive any further notice than the bare mention of their names. But the two cathedrals are national objects, to which all look with attention and a degree of veneration that requires a descriptive account, and some others are sufficiently distinguished to claim more notice than being merely named.

Cathedrals. St Paul's.

The cathedral church of St Paul's, the fame of which is only second to that of St Peter's at Rome, stands on an elevated spot, the best that could have been chosen for its display, above the north bank of the river Thames, on the position where similar ecclesiastical edifices, through a succession of centuries, had been placed

The best authority we have for the origin of this church, is that of its great restorer Sir Christopher Wren. His opinion that there had been a church on the spot, built by the Christians in the time of the Romans, was confirmed. When he searched for the foundations for his own design, he met with those of the original presbyterium or the semicircular chancel of the old church. They consisted wholly of Kentish ruble-stone, artfully worked, and consolidated with exceedingly hard mortar in the Roman manner, and much excelling the superstructure. He refutes the notion which had prevailed of its having been a temple of Diana.

The first church is supposed to have been destroyed in the persecution of Diocletian, and to have been rebuilt in the reign of Constantine. This was again demolished by the Pagan Saxons, and restored in 603, by Sebert, a petty prince, ruling under Ethelbert, King of Kent, the first monarch of the Saxon race, who, at the instance of St Augustin, appointed Melitus, the first Bishop of London. Erkenwald, the son of King Ossa, the fourth in succession after Melitus, ornamented the cathedral very highly, and improved its revenues from his own patrimony. For this he was canonized, and his relics, with those of his dress and furniture, were imagined to have virtues sufficient to restore the sick to health.

When the city was destroyed by fire in 1086, the church was burned, when Bishop Mauritius began to rebuild it, and laid those foundations, which remained till its last destruction by fire in 1666. Though that prelate lived twenty years, and his successor Beauvages enjoyed the see upon equal terms; yet, from the magnitude of the plan, it was still unfinished. Henry I. granted materials, consisting of part of the Palatine tower, exempted ships bringing stone from all tolls, and contributed to the work the tithe of all the venison in his forests in Essex.

After the death of the latter of these prelates, who had applied the whole revenues of the episcopate to the work, the building was interrupted, and the choir was burned in 1135. When that was restored does not appear; but the consecration did not take place till 1240, or 225 years after the work had been commenced by Mauritius.

The dimensions of this noble temple, as taken in 1309, were as follow: The length 600 feet, the breadth 120, the height of the west part from the floor 102, and of the east part 188 feet. The height of the tower was 260 feet, and of the spire, which was made of wood, and covered with lead, 274 feet. The whole area occupied by the church was a little more than three acres and a-half, being one-third more than the ground covered by the present cathedral. It required enormous funds to defray the expense of erecting such an edifice. The several monarchs who reigned during the long time it was building, resigned their revenues arising from the customs or taxes on the materials, and furnished wood from the royal forests; the prelates also gave up much of their revenues, and, what proved a still greater resource, their payments for indulgences and for commutation of penance. The Pope gave a release from sixty days' penance, the Archbishop of Cologne a relaxation of forty days, the Archbishop of Canterbury forty days; and each prelate thus excited his flock to contribute liberally.

The church contained numerous shrines and altars, richly adorned; the high altar especially, which sparkled with gems and gold, was the gift of numerous votaries. John, King of France, when a prisoner, first paid his devotions at the shrine of St Erkenwald, and presented at it four basins of gold; and the gifts at the obsequies of princes, foreign and British, were of immense value. On the day of the conversion of the tutelar saint, the charities were prodigious, as well as other expenses. Thus, on one such occasion, by order of Henry III., fifteen hundred tapers were placed in the church, and fifteen hundred poor persons fed in the church-yard.

The sanctity of the place did not prevent thieves and profligates of all denominations from assembling within the precincts, and there committing, under favour of the night, murders and every sort of crime. Edward I. gave permission to the dean and canons to inclose the whole within a wall, and to have the gates shut every night, to exclude disorderly people. Within the walls was the bishop's palace, where several of our sovereigns were lodged, and sometimes the foreign ambassadors, with their retinue, were quartered in it. Before the cathedral, was the famous Paul's Cross, a pulpit of wood on stone steps, and covered with lead, from which eminent divines were appointed to preach every Sunday. The court, with the mayor and aldermen, and the principal citizens, resorted to the place, and sat in the open air, but the king and his train had covered galleries. It was not only used for preaching, but also for promulgating laws, issuing papal bulls, anathematizing sinners, exposing penitents under censure of the church, and denouncing those who had incurred the displeasure of the crowned heads. Before this cross Jane Shore, the concubine of Edward IV., was brought, divested of all her splendour, after which she fell a victim to the malice of crook-backed Richard. One of the best uses to which this cross was applied, was perhaps the sermon on the thanksgiving for the victory over the Spanish Armada, in the year 1588, which was preached by command of Queen Elizabeth. The last sermon delivered at the cross, was by Dr John King, Bishop of London, in the year 1620, in the presence of King James I. and his court. attended by the city dignitaries. The object of it was to collect contributions for the repair of the cathedral. The spire had been set on fire by lightning, in 1561, and it was designed by the sums thus collected to restore it. Inigo Jones was called upon to furnish plans; and, in 1633, some slight beginnings were made, not to replace the spire, but to make alterations in the style of the western portico. But in this, little progress was made, and the fire of 1666, which destroyed the whole magnificent pile, made way for the exercise of the talent and judgment of Sir Christopher Wren, who planned and completed the existing magnificent fabric.

That great artist, Sir Christopher Wren, brought to the construction the whole weight of a powerful mind, then in the full vigour of manhood, and every step was thoroughly examined before it was made. The foundation was first to be provided for; and, having found the former remains, he was induced from curiosity to dig deeper, till he came to a layer of hard and close pot earth. He found that, on the north side, it was six feet thick, that it became thinner towards the south, and on the decline of the hill was scarcely four feet. On advancing farther, he met with nothing but loose sand; at length he came to water and sand, mixed with the shells of periwinkles and other sea fish, and, by boring, came at last to the beach, and under that the natural clay, which evinced that the sea had once occupied the space upon which St Paul's now stands. This sand had been one of those sand-hills so common on the coast of Holland and Flanders, as well as on our own shores. It was the opinion of our great architect, that all the space between Camberwall Hill and the hills of Essex had been a vast bay, but at low water a sandy plain; all which appeared in some remote age to have been embanked, possibly by the Romans, who were much employed in that useful kind of work, *paludibus emuniendis.*

The foundation being secured, the next step was to prepare the plan of the intended temple; and in this, as in every part of the subsequent progress, nothing was done that was not preceded by the closest consideration. Sir Christopher made a model in wood of his first conception for rebuilding the church in the Roman style. In it he had an eye to the loss of the Pulpit Cross, and had supplied its place with a magnificent auditory within, for the reception of a large congregation. This was approved of by men of excellent judgment, but laid aside under the notion that it had not a sufficiently temple-like form. A second plan was then made, selected out of the various sketches which he had drawn. On this design Sir Christopher set a high value; but this also was rejected, when the third, which produced the present noble pile, was approved and executed.

The first stone was laid by Sir Christopher on the 21st of June 1675, and it was completed by him in 1710; but the whole decorations were not finished till 1723. It is remarked as a singular circumstance that the edifice was begun and finished under the same architect, by one Strange, the only master-mason, and during the episcopate of the same prelate, Dr Henry Compton, Bishop of London; whereas the church of St Peter's, at Rome, was one hundred and thirty-five years in building, during the pontificates of thirteen popes, and carried on by twelve successive architects.

Having thus compared the time occupied in building these two temples, we may also here compare their respective dimensions. The height of St Peter's, to the top of the cross, is 437 feet, that of St Paul's is 340 feet. The length of the former is 729 feet, that of the latter 500. The greatest breadth of St Peter's is 364, that of St Paul's 180 feet. Although Sir Christopher Wren was most intimately acquainted with the whole process of planning, and the progress of building St Peter's, he cannot be charged with having copied from that stately pile. The whole was the conception of the mind of our celebrated countryman, and is thus exclusively, both in the planning and the execution, whatever may be its merits or its defects, of native growth.

The church is surrounded with an iron balustrade, placed on a dwarf wall; and at the west end is an area in which is the statue of Queen Anne, and at the other extremity, within the same inclosure, are burying-grounds for some of the adjacent parishes. The whole of the church is built of stone brought from the Isle of Portland, in Dorsetshire, and is now very much discoloured by time, and the effects of coal smoke. The principal entrance is under a noble portico facing the west, consisting of twelve Corinthian columns, supporting a portico above it of eight columns, of the composite order. The history of St Paul's conversion is sculptured on the entablature. On the centre of the pediment is a statue of the patron saint, and at the sides are those of St James, of St Peter, and of the four evangelists. The base or floor of the church is gained by ascending twenty-four steps of black marble, where noble folding doors open into the church. The corners of this front are furnished with two turrets, with each a dome, terminating in a gilded pine-apple. The southern turret contains a powerful clock, and the northern contains a fine peal of bells.

The north and the south entrances correspond with each other in the style of their architecture, being domes supported by Corinthian columns, with steps to ascend in a semicircular form. The eastern end of the building is of a semicircular shape, richly ornamented with a great variety of fine sculpture. The floor is composed of alternate slabs of black and white marble, and is a level surface to the choir, without any rising, as is commonly the case in cathedrals. The floor of the altar is interspersed with porphyry, but neither in the choir, nor in any part of the decorations, does the interior of the church correspond to the elaborate magnificence of the exterior.

The entrances from the three doors meet where, (as the whole of the pile is in the form of a cross), the upright part of that figure is intersected by the transverse part, or nearer the east than the west end of the buildings. Over this is the magnificent dome supported by columns of such extent as to give a kind of heavy look to the whole interior, though they are not too large to harmonise with the great weight they support. Few objects strike the beholder more forcibly than this dome, when surveyed from the floor whence it rises. Some of the trophies of victory acquired during the wars in which the country has been engaged, are placed here, as well as at the west end of the cathedral, in honour of the marine and land forces by whom they were gained.

The dulness which, fifty years ago, appeared to the spectator standing under the dome, when he looked not upwards but around him, has been relieved by the monuments, all executed since that period, to the memory of the eminent men that have disappeared from the theatre of their renown.

It was not till 1790 that the thought was entertained of filling this part of the cathedral with the memorials of the mighty dead, whether celebrated for their learning, their virtue, their talents, or their bravery. The scheme was no sooner suggested than it was acted upon, and the first monument was soon afterwards erected to John Howard, the philanthropic visitor and improver of prisons and of hospitals. It was the work of the late Bacon, with an inscription from the pen of Samuel Whitbread, the second member for Bedford of that name. Since that time the events of war have much contributed to increase the number of these honourable and sacred memorials. They must be here noticed, but it would require a long dissertation to describe the characters of the individuals, to whose memory they have been erected, or the merits of the various artists to whom the execution of them was entrusted. The fine monument to Lord Nelson was the work of Flaxman. The following can be briefly noticed only:—Sir William Jones, by Bacon junior; Earl Howe, by Flaxman, and Sir Joshua Reynolds, by the same artist; Captain Hardinge, by Manning; Sir Ralph Abercromby, by Westmacott; Lord Rodney, by C. Rossi; Captain Westcott, by Banks; Sir John Moore, by Bacon; Lord Collingwood, by Westmacott; Captain Duff, by Bacon; Captains Moss and Riou, by C. Rossi; General Dundas, by Bacon junior; Generals Craufurd and Mackinnon, by Bacon junior; Dr Johnson, Marquis Cornwallis, and Lord Heathfield, by Rossi; General Picton, by Gahagan; General Ponsonby, by Baily; Captains Hutt and Burgess, by Banks; General Bowes and Colonel Cadogan, by Chantrey; Captains Falkner and Millar, by Hayman; and Generals Hay and Mackenzie, by Langworth.

Over the entrance to the choir is a marble slab, with a Latin inscription thus translated: "Beneath lies Christopher Wren, the builder of this church and of this city, who lived upwards of ninety years, more for the benefit of the public than of himself. Reader, if you seek for his monument, look around you." The crypt beneath the cathedral contains inscriptions to Wren, to Bishop Newton, to the painters Barry and Opie, and to some other individuals; but the chief object of attention is the tomb of Nelson, whose body rests there near to that of his friend Collingwood. Other illustrious persons have been interred there, to whom hitherto no memorials have been erected, nor is it known if any such designs are contemplated, viz. Alexander Wedderburne, first Earl of Roslyn; Sir John Braithwaite, Sir Joshua Reynolds, Benjamin West, Sir Thomas Lawrence, Henry Fuseli, George Dawe, and Sir John Rennie.

In the choir the cathedral service is daily performed. On Sundays there are two services; and on the first Sunday of each term it has been the custom for the Judges, and the Lord Mayor and Aldermen, to attend in the morning. This part has a fine organ, supported by marble pillars of the Corinthian order. The throne of the bishop, and the seats for the city corporation, are of curiously carved wood. The reading-desk is formed of the extended wings of an eagle of bronze, standing on a pillar, and surrounded with gilded rails. An early service is performed in a chapel near the north-west corner of the church, which begins at six in the morning in summer, and at seven in the winter. The ecclesiastical officers appertaining to this cathedral, besides the bishop, are the dean, the chancellor, the precentor, the treasurer, four canons residentiary, twenty-four prebendaries, and one layman, the chancellor of the diocese, which includes the whole of London, of the counties of Middlesex and Essex, and a part of Hertfordshire.

Within one of the pews a door leads from the floor of the church, by a winding stair-case of 280 steps, to the circular gallery, at the foot of the interior of the dome, commonly denominated the Whispering Gallery; a name to which it is entitled, by the increased intensity of sound within its limits. This increase is such, that a whisper may be communicated from a person on one side to another opposite to him in the gallery, though the distance is 100 feet, if the voice of one and the ear of the other be directed to the wall. The effect was not designed, nor was it discovered till after the building had been completed. The sound, on shutting the gallery-door, seems like loud thunder. From this spot the paintings in the interior of the dome may be seen to great advantage. They were from the pencil of Sir James Thornhill, and admirably pourtray all the most striking events in the life of St Paul, as narrated in sacred history.

From this gallery the passage is short to another, which on the outside surrounds the bottom of the dome, and is known by the name of the Stone Gallery, from which, being higher than any of the surrounding buildings, a good view, in clear weather, may be obtained of the whole city and suburbs. From this point there is a further ascent of 254 steps in a number of staircases, or rather ladders with rails, to the upper exterior or the golden-gallery. As the way from one to the other passes through a vacancy left between the interior and the exterior dome, it is dark, and to those who first enter upon it alarming, but the guards against danger are quite sufficient to protect those who ascend. From the height of the golden gallery the view is necessarily more extensive, and comprehends the adjacent country to the hills of Hampstead to the north, and those of Surrey to the south; whilst the course of the river, both up and down, may be distinctly traced. Above this gallery is the ball and cross. These parts had been so affected by their weight, and the length of time they had been exposed to the influence of the weather, that fear was entertained for their safety. In 1822 they were taken down, and replaced by other ornaments of the same figure and dimensions, but of more appropriate materials, which were also of less weight. The whole, therefore, is now in a safe state. The present, like the old ball, measures six feet in diameter, and is capable, with squeezing, of containing eight persons, who may go there with safety, but they scarcely see more than they would in a covered copper boiler.

Nearly on a level with the whispering gallery, over the south aisle of the nave, is the library, furnished with a collection of books by Bishop Compton; but most remarkable on account of the curious floor, consisting of more than two thousand pieces of oak, curiously laid together, and for a most beautiful geometrical flight of steps.

The mechanical works in the southern turret, over the west end of the church, are curious and interesting. The great clock has a pendulum fourteen feet in length, and the weight, whose descent gives motion to the clock, is of one hundred pounds. The length of the minute-hands of the dials is eight feet, and of that of the hour-hands five feet five inches. The diameter of the dials is eighteen feet ten inches, and the length of the figures that indicate the hours two feet two inches and a half. The loud and clear-sounding bell which strikes the hours has been heard and distinguished at two miles distance, and, when the weather is clear, can be distinguished from all others in the metropolis. It is about ten feet in diameter, and weighs four tons and a half. It is never tolled except on the death of any member of the royal family, of the Lord Mayor or Bishop of London, er of the Dean of the Cathedral.

In the cathedral two meetings are annually held, which excite great interest, and usually attract considerable crowds of spectators and auditors. The first is that of the children of the several parochial charity-schools of the metropolis. These are marched under the care of their teachers, and placed in temporary galleries, rising above one another under the dome, presenting the gratifying spectacle of from eight to ten thousand children of both sexes, neatly clothed, who are receiving gratuitous instruction. Divine service is performed, and a sermon by some eminent divine is preached, when the whole of the children join in singing the hundredth psalm to Luther's noble tune, the effect of which is uncommonly interesting and beautiful. The day finishes with a collection for the schools and the occasion.

An annual assemblage held in St Paul's, is intended to support the charitable institution for the benefit of the sons of the clergy. Handel's grand Dettingen Te Deum, with some of his most beautiful choruses and appropriate anthems are performed by a powerful orchestra, supported by the principal gentlemen, both lay and clerical, belonging to the three choirs of St Paul's, Westminster Abbey, and the Chapel Royal, who make a point of attending and of performing gratuitously. A rehearsal precedes the grand performance; and at both very large sums are obtained as contributions to the benevolent institution.

Some of the dimensions of the cathedral have been already stated, and the others are as follow. The breadth from north to south, at the transept, is 285 feet; the height, exclusive of the dome, is 110 feet; the circuit 2292 feet; and the ground it covers 2 acres 16 perches and 70 feet.

In the reign of James I. and of Charles I., the body of the cathedral was the common resort of the politicians, the newsmongers, and the idlers of the day. It was called *Paul's Walk*, and the frequenters known by the name of Paul's walkers, as is mentioned in old plays and other books of that time. The *Microcosmographia*, printed in 1626, gives a ludicrous description applicable to the cathedral, and illustrative of the manners of London, which is worth inserting here in the quaint phraseology of the period. "It is the land's epitome, or you may call it the lesser ile of Great Britaine. It is more than this, the whole world's map, which you may discerne in its perfectest motion, justling, and turning. It is a heap of stones and men, with a vast confusion of languages, and, were not the steeple sanctified, nothing liker Babel. The noise in it is like that of bees, a strange humming or buzze, mixed of walking tongues and feet. It is a kind of still roare, or loud whisper. It is the great exchange of all discourse, and no business whatsoever but is here stirring and afoot. It is the synod of all pates politicke, jointed and laid together in the most serious posture; and they are not half so busie at the parliament. It is the anticke of tailes to tailes and backes to backes; and for vizards, you need go no further than faces. It is the market for young lecturers, whom you may cheapen here at all rates and sizes. It is the general mint of all famous lies, which are here, like the legends popery first coyn'd and stampt in the church. All invertions are emptyed here, and not few pockets. The signe of a temple in it is the thieves sanctuary, which robbe more safely in the croud than a wildernesse, whilst every searcher is a bush to hide them. It is the other expense of the day, after plays, taverne and a baudyhouse; and men have still some oathes left to sweare here. It is the ears brothell, and satisfies their lust and ytch. The visitants are all men without exceptions; but the principal inhabitants and possessors are stale knights and captains out of service; men of long rapiers and breeches, which after all turne merchants here, and trafficke for newes. Some make it a preface to their dinner, and travell for a stomacke; but thriftier men make it their ordinary, and board here verie cheape. Of all such places it is least haunted with hobgoblins, for if a ghost would walk, move he could not."

Westminster Abbey.

The ancient history of this magnificent pile is necessarily involved in the common obscurity of remote ages. If any credit can be given to tradition, it stood originally on an island in the Thames, called Thorney Island. But if it was once an island, it must have been by the stream dividing, and one branch of it, above Millbank, running in a direction towards the spot where the Chelsea water-works now stand, from thence by Pimlico into the Park, and then rejoining the other branch somewhere about Scotland Yard. Another tradition places it on the site of an ancient heathen temple dedicated to Apollo. Having barely noticed these reports, we come to a period more within the compass of accurate history. Wedmore, who was a man of great learning, and examined all the extant records, fixes the date of the abbey and buildings between the years 730 and 740. It was in all probability injured if not destroyed by the Danes, for it was rebuilt by King Edgar, at the urgent suggestion of Dunstan, and by him appropriated to the order of the Benedictines, with sufficient endowments for the support of twelve monks.

In the turbulent times that followed the reign of Edward the Confessor, it was injured by the sacrilegious fury of contending parties, which induced that pious monarch to renovate and improve it. The Norman style of architecture was adopted, as appears from fragments of the building which were recently in existence, and from a few which still remain. Considerable revenues were established for the monks by the king, and the nobles, stimulated by him, contributed largely. During the incumbency of the Abbot Lawrence, about the year 1159, many repairs were executed on the out-buildings, and the roof, which had suffered severely, was replaced by a new one, and for the first time covered with lead.

The whole building was, however, taken down and rebuilt by the same prince. It was begun in 1425, but not finished till fourteen years later, after his decease. An accidental fire destroyed the roof, but by the contributions of the king, of the monks, and of other pious persons, it was repaired, and restored to the beauty and splendour which it still displays. A chapel was added at this time, on the spot where now stands the curious specimen of the Gothic architecture of its age, known by the name of Henry VII.'s Chapel, it having been built in the reign of that prince, who laid the first stone of it on the 24th of January 1502. His design was to preserve it as a burying-place for himself and the other members of the royal family.

During the long interval between the death of Henry VIII. and the accession of William and Mary, little care was taken to preserve this ancient edifice. It had been somewhat defaced in the civil wars, and generally neglected afterwards; but soon after the Revolution, the parliament voted a considerable sum for the reparation, and Sir Christopher Wren was appointed the architect, to superintend the expenditure. The defective parts were then duly repaired and strengthened, and two new towers were erected, which, by some critics, have been thought not to harmonize with the general structure, which is Gothic, whilst the towers are decorated with Roman ornaments.

The principal object of attention in the exterior, with the exception of the towers and of Henry VII.'s Chapel, is the magnificent Gothic portico leading into the north cross, or Solomon's gate, which has been adorned by a window of modern design, admirably executed.

In the interior, the Gothic arches separating the nave from the side-aisles are supported by forty-eight pillars of grey marble, and are so disposed that the whole body of the church may be seen on entering the western door, which has a most commanding appearance.

The choir is of less ancient date than other parts. It is in the Gothic style, and it is divided from the nave by an elegant screen of stone, erected from the designs of Mr Blore. The altar-piece is of ancient workmanship renewed; and the Mosaic pavement in front of it is also very curious, said to have been executed by Richard de Ware, formerly Abbot of Westminster.

On the northern side of the choir are some monuments which deserve notice, chiefly on account of their antiquity. These are to the memory of Aymer de Valence, Earl of Pembroke, and his countess, and of Edward Crouchback, Earl of Lancaster; and on the south are two, remarkable for the same reason, to Sebert, the original founder of the abbey, and to Anne of Cleves.

The roof of the lantern, which was destroyed by an accidental fire in 1803, has been rebuilt, but in a style better harmonizing with the rest of the building than the one which preceded it, and is now richly adorned with carving and gilding.

There are within the structure several chapels, all of which will reward the antiquary for the time occupied in their inspection. Two of them pre-eminently require some description. The chapel of Edward the Confessor is at the east end of the choir, and contains the shrine of that monarch, a piece of workmanship affording a fine specimen of the skill of the age in which it was executed, that of Henry III. In this are the tombs of Editha, the Queen of Edward, of Henry III., of his son Edward I., and several other royal personages. Here are preserved the iron sword of Edward I., and a part of his shield, and the coronation chairs. The most ancient of these chairs was brought from Scone, in Scotland, with the other regalia of that kingdom, by Edward I. in 1297, and has been used at the coronation of all our kings to the present time. The other chair was constructed for the coronation of Mary, the wife of William III. The skreen of this chapel is adorned with several statues, and with various legendary hieroglyphics respecting the Confessor, executed in basso-relievo.

The chapel of Henry VII. was commenced in 1502, and was executed, according to some, under the direction of Sir Reginald Fox, or, according to others, by Bolton, the Prior of St Bartholomew's. It is built of Yorkshire stone, and the expense of it is said to have been L.14,000. It is at the eastern part of the abbey, and constructed in the florid Gothic style. The exterior is adorned with fourteen octagonal towers jutting from the building in different angles, and ornamented with exquisite sculpture. A thorough repair of it was executed between the years 1810 and 1822, for which parliament voted the sum of L.42,000.

The steps by which the ascent to the chapel is gained are of black marble, under a portico which is at the entrance, with gates of brass, most curiously laboured. The lofty stone ceiling contains a variety of figures. The stalls for the Knights of the Bath are of wood, now of a deep brown colour, with Gothic canopies beautifully carved, and the seats of the esquires to the knights correspond in their workmanship, and are all ornamented with curious devices. The pavement is of black and white marble. The banners of the knights project over the stalls, and the whole has a most imposing effect. On entering, the tomb of the founder and the brass chapel present themselves, and at the end are the chapels of the Dukes of Richmond and Buckingham of past ages. The windows were formerly of painted glass, and in each pane a white rose, the badge of the royal house of Lancaster. The roof is nearly flat, and is supported on arches between the nave and the side aisles, which are turned upon twelve Gothic pillars, curiously adorned with figures, fruit, and foliage.

The chapel was destined to the sole purpose of interring the members of the royal family; and the rule has been adhered to so far, that none but those of the blood-royal have found a sepulchre within the vaults beneath it. In the north and south aisles of the chapel are many monuments to royal and noble persons; in the former, that of Edward V., of Queen Elizabeth, of Mary Queen of Scotland, and some others; and in the latter, of Monk Duke of Albemarle, of Margaret Countess of Richmond and Derby, mother of King Henry VII., and many others.

In both the naves, at the west end, and in Poet's Corner, are numerous monuments to princes, nobles, statesmen, land and sea warriors, divines, lawyers, philosophers, historians, poets, painters, sculptors, musicians, dramatists, and others, distinguished for their rank, virtue, valour, patriotism, learning, or taste; a list of which, with due notices, however short, would fill a volume.

Besides the church, many of the ancient appendages of the abbey remain, such as the cloisters, filled with monuments, in a quadrangle, with piazzas around it; the chapter-house, now filled with ancient records, amongst which is a fine copy of Doomsday-book, still in excellent preservation, whose leaves are only allowed to be turned over by silver tongs; the crypt beneath the chapter-house, the roof of which is supported by plain ribs, diverging from a short round hollow pillar, and having walls eighteen feet in thickness; and the residence of the Dean, and of the several ecclesiastics attached to the church, who assist daily in the public service in the choir.

Not far from the abbey stood the sanctuary, the place of refuge once granted to criminals of certain classes. The church belonging to it is supposed to have been the work of the Confessor. Edward V. was born within the precinct; and here his unhappy mother took refuge with her younger son Richard, to secure him from his cruel uncle. Near to it was the almonry, where charity was dispensed; but it is more remarkable as being the place in which the first printing-press was established in England, by William Caxton, in 1474, and where the first English book was printed, written, according to tradition, by Thomas Milling, then abbot, and entitled "The game and play of the Cheese."

The length of the abbey, exclusive of Henry VII.'s chapel, is 416 feet on the outside, and 383 within. The west towers are 225 feet in height. The breadth of the church at the transept is 203 feet, the height of the nave 102 feet, the length of the choir 156 feet, and the breadth of it 28 feet.

The clergymen belonging to this church are the dean, eleven prebendaries, a precentor, and a chapter clerk, and besides these there is an organist, and an establishment of choristers.

ter-
e.

There is an establishment neither strictly to be classed as ecclesiastical, nor with one of the hospitals, for the cure of the diseased, but deserving notice, which may be given to it in this part of the article. The *Charter-House* is in a small square of the same name near to Smithfield. A house for Carthusian monks, founded by a Sir Walter Many, a successful officer in the wars with France under Edward III., gave to this establishment its existence, and (with a slight change) its name about the year 1349; it is situated on a piece of ground which he had purchased for the interment of those who had died of the plague, to which, according to some, fifty thousand, and according to others one hundred thousand had fallen victims. Ralph Stratford, Bishop of London, bought another piece of ground adjoining, on which he built a chapel, and inclosed a burial-ground called Pardon Church-yard, in which criminals and suicides were buried.

The Carthusians regulated these premises till the suppression of monasteries, when there were twenty-four monks of that rigid order. Though the last prior acknowledged the king's supremacy, this did not save the institution. It was seized with others, and then granted to persons who sold it to Thomas Duke of Norfolk, who again disposed of it to a charitable individual Thomas Sutton. This man, possessed of vast wealth, and devoted to beneficent purposes, converted his purchase into a magnificent hospital, consisting of a master, a preacher, a head and second master, with forty boys, and eighty decayed gentlemen, who had been soldiers or merchants, besides physician, surgeon, and registers. 'Having, in the reign of James I., obtained an act of Parliament for the purpose, he endowed the institution with L.20,000 in money and landed estates of the annual value of L.4500.

Scarcely any of the ancient conventual buildings are now standing, but the present pile was chiefly erected by the Duke of Norfolk before he had sold it to Sutton. The chapel is a venerable edifice with Gothic windows, in which, in painted glass, are the arms of the founder. The house of the master is a curious suite of rooms. The old court-room is richly decorated with carving and pointing. The library, the gift of a Mr Wray, is a fine old collection.

This charity is under the government of trustees, who are usually selected from the ranks of the most eminent public men of the country. They have the appointment of the masters, physician, surgeon, chaplain, and other officers, who, besides their salaries, are provided with residences and other conveniences.

This has become one of the first classical schools in the kingdom. Besides those on the foundation there are many other scholars, who board in houses near it, in which some of the junior teachers superintend their conduct whilst out of school hours. The number of such scholars has varied much, according to the supposed aptitude of the master for the time for communicating instruction. The youths educated at the Charter-House upon the foundation have exhibitions at the university; and the hospital having the patronage of nine livings, those educated in it have the preference in the presentations.

hes.

As it is not possible in this work to notice all the numerous churches in the metropolis, and as a selection of those most remarkable must be made, it seems best to begin that selection by some of the sacred edifices in Westminster, where they are generally larger than those in the city, and where the number of them is in a much less proportion to the population than in the eastern division of London.

The church of *St James*, in Piccadilly, was built in the latter part of the reign of Charles II., but was not consecrated till the accession of his brother James. The great extension of London made new churches desirable, and a part of the parish of St Martins-in-the-Fields was separated from it, and attached to this new erection. It was built on a piece of ground where the house of the gay Henry Jermyne, Earl of St Albans, the favoured lover, perhaps the secret husband, of Henrietta Maria, the widow of Charles I. formerly stood. It was built by Sir Christopher Wren, partly of stone, and parly of brick. It is well proportioned, being 85 feet long, 60 broad, and 45 high; and, having deep galleries on both sides and at the end, it is adapted for a large audience. The most remarkable object in the church is a fine font of white marble, the work of Granlin Gibbons. It is supported by the tree of life; the serpent is offering the forbidden fruit to our first parents who stand beneath; on one side is engraved the Baptist baptising our Saviour; on another St Philip baptising the Eunuch; and, on the third, Noah's dove bringing the olive branch, the symbol of peace to mankind. The chancel above the altar is enriched by some beautiful foliage in wood by the same great artist. The living is a rectory, and the right of presentation to it is vested in the Bishop of London at present; Lord Jermyn had one turn in three, but conveyed it to the episcopate. The pulpit of this church has been occupied by some of the most pious and learned ministers of the established church, who have been successively the rectors.

Church of *St Martins-in-the-Fields*. This building was erected in 1721, on the site of an ancient church, said to have been constructed 500 years before. It is remarkable for its magnificent façade, with a portico of eight Corinthian columns, which is seen to great advantage as the termination of the long street of Pall-Mall. It is 140 feet in length, 60 in breadth, and 45 in height, being furnished with deep galleries, and with seats in the aisles; it will accommodate 3500 persons. The interior is handsome, and the decorations fine, but at present they need both painting and gilding. The ceiling is elliptical, which is deemed favourable for hearing. Near to it is the vicarage-house, recently built at the sole expense of Dr Richards, the late vicar, in a superior style. The tower is lofty and handsome, and contains a peal of twelve bells. Around it, under the pavement, are some recently constructed catacombs finished in 1830, and the parish has besides a burying-ground at Camden Town.

Church of *St John the Evangelist* at Milbank, Westminster. This is one of the churches built in the reign of Queen Anne, by Sir John Vanbrugh, the successor of Sir Christopher Wren. It is a singular building, too much incumbered with ornaments. On the north and south sides are porticos supported by massive pillars, and at each of the four angles is a stone tower with a pinnacle. The front is an elegant portico, supported by Doric columns, which order is continued in pilasters round the building. The interior was much improved in 1825, and it is now lighted with gas. It is 140 feet in length, 90 in breadth, and 50 in height, and can accommodate 2500 hearers. Over the altar is a painted window representing our Saviour's descent from the cross, and the Apostles St John and St Paul.

Church of *St Georges*, Hanover Square. This edifice was erected in 1724, being one of the fifty built under the act passed in the reign of Queen Anne; but the ground on which it stands was presented to the parish by the liberality of General Steward, who bequeathed L.4000 for the purpose. Next to St Martins-in-the-Fields, it is the handsomest church in London. The fine portico consists of six Corinthian columns, with an entablature and pediment;

but from being in a street, it is not seen to the greatest advantage. The steeple is very magnificent. The interior is executed with more expense than taste. The altar-piece, painted by Sir James Thornhill, represents the Last Supper. The church is 100 feet in length, 60 in breadth, and 45 in height, and can accommodate 2500 hearers. This parish has also a church at Pimlico, and a burying-ground near Tyburn turnpike.

Church of *St Margaret.* This building is placed in such a situation as to impede the view of Westminster Abbey, and by contrast with that edifice, to appear less worthy of notice than it would be in another situation. It is the church of the House of Commons, with a pew for the Speaker, and a gallery for members. On this account it has often been repaired at the public expense, and its decorations and ornaments are of great value. On the altar table is a basso-relievo, representing Christ at Emmaus. There is a fine painted window, prepared at Dort in Holland in the reign of Henry VII., representing the crucifixion. The church is 130 feet in length, 65 in breadth, and 45 in height, and accommodates 2000 auditors. In one of the aisles is a tablet to the memory of Sir Walter Raleigh, who was buried there. In the enclosure by the church, a bronze statue to the memory of Mr Canning, by Westmacot, has been erected.

St George's Church, Bloomsbury, was one of the fifty ordered to be built in the reign of Anne, but it was not finished till 1731, when the statue of George I. was placed on the top of the tower. It was built by Hawksmoor, and, contrary to the general practice, extending from north to south. It has an admired portico of eight Corinthian columns. In it are some handsome monuments, especially one to the late Charles Grant, constructed at the expense of the East India Company. The church is 110 feet in length, 90 in breadth, and 50 in height, and can accommodate 2000 auditors.

The church of *St Mary-le-Strand* was built by Gibbs, under the act of Queen Anne, and completed in 1717. It is an elegant pile of architecture, with an entrance at the west end by a flight of steps in a circular form, which leads to a portico of Ionic columns covered with a dome, and the columns in the same order are continued in pilasters round the whole building, and in the intercolumniations are niches tastefully ornamented. It is 70 feet in length, 30 in breadth, and 48 in height, and has a modern painted glass window.

St Clement Danes Church, in the Strand, was built in 1680 by Sir Christopher Wren. It is built of stone, with two rows of windows, the lower plain, but the upper ornamented; and the termination is by an attic. On the north, as well as on the south side of the front is a portico with a dome, supported by Ionic columns. The steeple, which is lofty and beautiful, was erected by Gibbs in 1719. The church is 96 feet long, 63 broad, and 48 high. Both these churches are inconveniently placed, as the noise, from the constant succession of carriages passing close to them, prevents the distinct hearing of the preacher's voice.

The church of *St Anne*, Soho, in Dean Street, was built in 1685, on account of the great increase of inhabitants in the parish of St Martin's-in-the-Fields, of which this district then formed a part. It received its name from the Saint, in compliment to the then Princess Anne of Denmark, who afterwards became Queen. It is a brick building, 110 feet long, 60 broad, and 40 high, and is rendered singular by a circular tower, surmounted by a large ball, containing a clock with four dials. There is a fine organ, a present from King William III., and two paintings of Moses and Aaron around the tablets on which the decalogue is painted. At the back of the church is a tablet in remembrance of Theodoric, King of Corsica, who was interred there.

The most remarkable of the churches in the western part of the metropolis that have been opened within the last eighteen years are the following:—

All Souls Church, in Langham Place, is a beautiful but singular structure, erected in 1824, from the designs of Mr Nash, and contains space for 1800 persons. The steeple consists of a circular tower, surmounted by a cone. The tower rests on a flight of steps, and the lower part is surrounded by a peristyle of twelve Ionic columns, the capitals of which are profusely ornamented. The base of the cone is also surrounded by a peristyle consisting of fourteen Corinthian columns, supporting an entablature and balustrade. The cone is fluted and carried to a point, without the usual addition of either weathercock or vane. The interior is very pleasing; three sides are occupied by galleries, and the fourth by the altar, which is adorned with a painting by Westall, of Christ crowned with thorns. Above the front of the galleries rises a colonade of Corinthian columns, supporting the ceiling, which is enriched with sunk panels.

The new church of *St Luke's*, Chelsea, which was consecrated on the 28th of October 1824, is one of the most beautiful edifices, in the Gothic style, that has been produced of late years. It is built of brick but faced with stone, and is divided into a nave and aisles. At the east end is a large window and splendid altar screen; and at the west end is an organ, built by Nichols. The church is 130 feet long, 61 wide, and 60 high, and it accommodates 2000 persons conveniently. It has a handsome tower with pinnacles at each angle, the height to the top of which is 142 feet. In it is an excellent peal of bells. The architect of this work was Mr Savage.

Marylebone New Church, in the New Road, was originally designed as an additional chapel of ease to the parish; but when the interior had been fitted up and arranged, it was so much admired, that it was thought expedient to make it a parish church. A small stone cupola, which had been erected, was taken down, and the present tower, adorned with representations of the winds, substituted. The front was increased in length; and the portico of six Corinthian columns, was tastefully attached to the building. The interior is rendered remarkable by a double gallery. The organ is over the altar, and stands at the south end of the church; and a picture, by West, of the nativity, forms the altarpiece. The foundation was laid in July 1813, and the consecration was performed in February 1817. The length of the church is 125 feet, the breadth 70, and the height 53. The height of the tower is 154 feet, and the width of the portico 20 feet. The builder was Mr Hardwicke. At this church more than three thousand baptisms are annually performed.

Christ Church, in Woburn Square, is an elegant edifice, completed in 1833. It is in the style of the architecture which flourished in this country in the fourteenth and fifteenth centuries. The principal front has a tower, which is united to a spire 150 feet in height. There are five entrance doors in the front, and the same number of windows, with mullions and rich tracery over them. The interior, calculated for 1500 persons, is a square of 70 feet each way, and has an height of 48 feet. Four massive pillars form a transept, and support arches; the arms of the transept being equal to the length of the nave, and thus a Greek cross is described. The great east window is enriched with mullions and elaborate tracery, and being 28 feet by 13 becomes an important feature in this elegant church.

The new church of *St Pancras* was consecrated in May 1822. It is built of brick, but faced with Portland stone, and the design of it by Mr Inwood, is in imitation of the Temple of Erectheus at Athens. The portico is a beautiful object, consisting of six Ionic pillars, beneath which are three doors, the centre of which is an exact representation of the entrance to the Greek temple. At each end of the church are two projecting wings, designed for the registry and vestry room, and formed on the model of the Pandroseum, which was attached to the Temple of Erectheus. The steeple, which is 160 feet in height, is also from the Athenian model, being an imitation of the Temple of the Winds. The interior, which is 170 feet in length, and 60 in breadth, is particularly elegant, the windows being composed of ground-glass, with coloured borders; and the galleries supported by pillars taken from casts of the Elgin marbles.

The church of *St Giles'-in-the-Fields*, was erected in the year 1730, on a spot where formerly stood an hospital, in the front of which Sir John Oldcastle was burned for his religious opinions in the reign of Henry V. It is a fine building, with a tower at the west end of the Doric and Ionic orders, terminated by a steeple, the clock of which is now illuminated at night. The ceiling is arched, and supported by Ionic pillars. At the north-west corner of the churchyard is a handsome portico called the Resurrection Gate, having over it a fine bronze representation of that expected event executed about 1687.

St Stephen's, Holborn Hill, is one of the churches built under the direction of Sir Christopher Wren in 1670. It is 126 feet in length, exclusive of the ambulatory at the west end, is 58 feet in breadth, and 35 in height, and calculated for 2000 auditors. The tower is 140 feet in height, with four modern spires at the angles. The altarpiece, of the Corinthian order, and the roof, supported by twelve Tuscan pillars, produce a very fine effect.

St Peter's Church, Pimlico, is a chaste building of the Ionic order, erected in 1826 from the design of Mr Hakewell. The portico consists of six fluted columns, supporting a pediment, behind which is a quadrangular tower, crowned with a spherical dome and cross, and has a fine effect. It accommodates 1680 persons. The altar-piece s Christ crowned with thorns, painted by Hilton.

The churches in the city, though more numerous than n the other parts of the metropolis, are in general much smaller, and so are the congregations; for in some parishes so many houses have been taken down in order to erect public buildings, and so many of the more substantial tradesmen and merchants prefer to live either in the country or at the west end of the town, rather than at their houses of business, that but few in comparison attend the parish churches, whilst those churches in the more fashionable or more pleasant parts are in general crowded to excess, especially if the preachers are at all popular.

Christ's Church, in Newgate Street, is one of the largest of the city churches. It was built by Sir Christopher Wren on the site of a former church, which, before the Reformation, had belonged to the Franciscan monks. It s a beautiful structure, but hidden by the houses that surround it. The tower is square and lofty. The pulpit is curiously carved with representations of the Last Supper, and of the four evangelists. The font is of white marble, adorned with *alto relievos*. The western window is ornamented with the royal arms and painted glass. The number of eminent persons interred in the vault is very great. Annual sermons are preached here at Easter before the Lord Mayor, Aldermen, and the Governors of royal hospitals, known as Spital sermons.

The *Church of St Mary-le-Bow*, or *Bow Church*, in Cheapside, was built by Wren in 1673, upon the spot where a very ancient one stood built on arches, from which t derives the addition to its name. The tower is very beautiful, being 200 feet in height, and furnished with a very celebrated peal of bells; and was in 1820 improved and strengthened. The Bishop of London is consecrated here, and the lectures are preached in pursuance of the will of Mr Boyle, in defence of the Christian religion, many of which have been published and maintained the highest rank amongst theological writings.

St Dunstan's in the West, in Fleet Street, was one of the oldest churches in London, and none more attracted the attention of passengers, owing to its clock, at which appeared two coarsely clad athletic figures with clubs in their hands, who struck a bell to give notice of the hours and quarters of hours. These have been sold to the Marquis of Hertford, with their machinery, to ornament his villa in the Regent's Park. The sale was made when the church was rebuilt in 1834. It is now a handsome Gothic edifice, but placed thirty feet farther back than before. The southern front is a tower of freestone, square as high as the belfrey, which is lighted by four large windows. Above these windows an octagonal battlement, springing from corbelled heads, surmounts the tower, the four corners of which are ornamented by pinnacles; and thence rises an octagonal lanthorn, each angle having a buttress and fencal, and each front two windows, one above the other; the whole being terminated by a richly-ornamented crown parapet. The entrance doorway is finished with rich tracery, and flanked by two buttresses. The arms of the kingdom and of the city are placed upon each side of it, and four blank shields over it; an iron rail and gate separating the whole from the street. The interior of the church is appropriately finished in a style harmonising with the exterior, and the ornaments are extremely rich. The total height of the tower is 130 feet. The accommodation provided is for about 900 persons. The whole well deserves notice, and does great credit to the skill and taste of the architect, Mr John Shaw, who died just as the work was finished.

The church of *St Saviour*, in the Borough of Southwark, belongs to two parishes, St Margaret's and St Mary Magdalen. It was formerly a priory, but, from various repairs, little of its original architecture remains. It is, however, a noble fabric, with three aisles running east and west, and a cross aisle. It measures 270 feet in length, 54 in breadth, and 47 in height; and the breadth of the cross aisle is 109 feet. The tower, which is surmounted by four pinnacles 150 feet high from the ground, is remarkable as the spot from which Hollar took his views of London, both before and after the great fire. The *Lodge Chapel*, at the east end of this magnificent church, and which forms its most interesting part, had undergone some insufficient repairs, and being still dilapidated, it was proposed to pull it down, to avoid the great expense which was deemed necessary to preserve it. This project having been opposed by many of the admirers of our Gothic architecture, a successful appeal was made to the public in order to raise the funds necessary to save it from destruction. The necessary sum having been obtained, the work is now proceeding with great rapidity, every part being made an exact *fac-simile* of the original fabric. By an act of Parliament of the session 1833, an additional width was given to the opening in the main street leading from the new bridge, which is now such as to display the whole of the fine church of St Saviour to the greatest advantage.

The church of *St Stephen's*, Walbrook, though but little known, is considered by critics as the best specimen of the taste of Sir Christopher Wren, who built it after the fire, according to a design borrowed from the celebrated Palladio. The plan is original, but chaste and beautiful. The dome, supported by eight arches, springing from eight Corinthian columns, is light and scenic in its effect, and scarcely corresponds with the simple solemnity of our religious worship. Over the altar is a fine picture representing the interment of St Stephen, by West. The church is 75 feet long, 36 broad, and the central roof 34 feet high.

The great number of the churches in London forbid even an enumeration, but it may be confidently affirmed that, varying as they do in age, in style of building, in decorations, and in extent of accommodation, all of them are kept in excellent order, as regards cleanliness, neatness, and warmth, and have the service performed with punctual adherence to the prescribed formularies.

The new churches and chapels which have been built or rebuilt under the direction of the commissioners for building churches, from sums partly raised by voluntary contributions, and partly from the aid supplied from the Parliamentary grant, are as follow:—

	Opened in
Trinity Church, Newington Butts,	1823
St John the Evangelist, Waterloo Road,	...
St Mary's Wyndham Place, Bryanston Square,	1824
St Peter's, Rivington,	...
All Saints, Poplar,	...
Hanover Chapel, Regent Street,	...
Regent Chapel, Sidmouth Street,	...
Somer's Town Chapel,	...
Camden Town Chapel,	...
Christ's Church, Marylebone,	1825
St John's Hoxton,	1825
Bethnal Green,	...
St Barnabas, near Goswell Street,	1826
Trinity Church, Marylebone,	...
St Mary's, Haggerstone,	...
St Peter's, Pimlico,	...
St Paul's, Ball's Pond,	1826
Trinity, Brompton,	...
St Mark's, Clerkenwell,	1828
North Audley Street Chapel, or St Mark's,	...
St Philip's, Regent Street,	...
Trinity Church, Sloane Street,	...
St Andrew's, Saffron Hill,	1831

All of these are capacious buildings, capable of accommodating from 1500 to 2200 hearers each, and about two-thirds of the sittings are free to all persons. The total number of churches of the established religion in the metropolis, according to the limits here presumed, is 149, and of chapels 88. These 237 buildings may, on an average, accommodate about 1200 persons in each; for though a few of the older churches are small, yet the vastly greater capacity of some of the old, like St Martin's and others, and all the new, and those in Westminster of all ages, more than compensate for the narrow limits of the more ancient edifices. There is thus church accommodation for 255,000 persons.

Other places of worship.

Besides these structures destined for the national church, there are numerous buildings appropriated to the various sectaries who prefer other modes of worship, or adopt different professions of faith. As they are varying bodies, it is difficult either to estimate the number of their places of worship, or to classify them with much confidence of accuracy. Though the buildings occupied by dissenting congregations are for the most part neat and commodious, few of them have that imposing exterior which demands attention; and many of them are in courts, or lanes, or narrow streets, or in the outskirts of the metropolis.

There are two, however, sufficiently distinguished from the rest to merit notice. The Roman Catholic church in Moorfields, a modern structure of great capacity, is a plain building, but ornamented with paintings which produce a fine effect. The altar is adorned with marble columns, and there is a fresco painting of the Crucifixion, on which the light from behind is thrown so as to produce a fine effect. On the ceiling are representations of the Virgin Mary, of the infant Jesus, and of the four Evangelists, surrounded by paintings of the principal events in the life of our Saviour, all executed by M. Angelo, an Italian artist.

The members of the Established Church of Scotland resident in London have lately erected an edifice for the celebration of their form of worship in Regent's Square, near to Gray's Inn Lane. The building is in the Gothic style, and may vie with most of those lately built for the English church. It is 100 feet in length, and 63 in breadth, and is capable of containing 1800 persons. It is after a design of Mr Tile, and well executed.

The number of places of worship, other than those of the Established Church, is 207, of which 16 belong to foreign Protestants, Dutch, Danish, Swedish, French, Swiss, or German, and they are both of the Lutheran and of the Calvinist communion. The Roman Catholics occupy seventeen chapels, four of which belong properly to foreign ambassadors. The Jews have six synagogues. The others are used for the public worship of the various descriptions of Protestants. Twelve of these are of the Scottish nation, and presbyterians either of the Established Kirk, or of some of the secessions from it. The Wesleyan Methodists, including the different branches into which the sect is divided, have seventeen chapels. The Whitfield Methodists, or those of Lady Huntingdon's connexion, possess five chapels. The Quakers, or Friends, occupy six meeting-houses. There are eighty-eight chapels denominated Calvinist, many of which are Independent, and some few Presbyterians, but the most are occupied by congregations collected by some popular preacher, who do not make any specific opinions a centre of union, and have little connexion with each other. There are forty-four meeting-houses of Baptists, comprehending both Arminians and Calvinists, but the latter are by far the most numerous; in some of these the service is performed in the Welsh language. The Arians and Socinians, calling themselves Unitarians, have eight chapels. There are, besides, small chapels used by Swedenborgians, Sandemamonians, Huntingdoneans, Moravians, and Free-thinking Christians, but not more than one to each sect. As many of these chapels are very small, and only a few of them large, they do not probably upon an average provide room for more than half the number of auditors that can be accommodated in the churches and chapels of the established faith. It is doubtful, if taking one with another, they include more than 500 persons each.

Institutions connected with religion.

The religious zeal of the metropolis is not more evinced by the regard paid to the edifices of devotion than it is by the anxiety displayed by numerous societies formed for the promotion of piety and virtue. These are of various descriptions. The distribution of Bibles and other pious writings is the express object of some of these associations. Of these two are pre-eminent by their extent. One of them, called the Society for Promoting Christian Knowledge, consists of members of the National Church, and disseminates the sacred Scriptures, the Book of Common Prayer, and other books of practical religion. The other, composed of Christians of all religious denominations, confines its distribution to the Bible alone. It is called the British and Foreign Bible Society, and employs persons to translate the holy books into languages in which they were never seen before, and in conveying them to the countries where they are gratuitously dispersed. Its distribution in this country is very considerable. Both these societies have various branches connected with them, some in London, and others more numerous in the different parts of the kingdom, and these branches, like the parent society, collect money and disseminate pious books. There is an old society called the *Society for Promoting Religious Knowledge*, chiefly consisting of Calvinistic dissenters, who distribute their writings amongst the poor. There is likewise a Naval and Military Bible Society, and a Merchant Seamen Bible Society, whose names are significant of their objects. The pious desire to spread the knowledge of Christianity amongst unbelievers in distant countries has given rise to the following missionary societies:—

Society for Propagating the Gospel in foreign parts, which was established in 1701, and receives aid from government.

Society for Conversion of Negro Slaves in the British West India Islands was incorporated in 1794.

Church Missionary Society for Africa and the East in 1800.

Baptist Missionary Society in 1792.

London Missionary Society in 1795.

Wesleyan Methodist Missionary Society in 1802.

Moravian Missions of the United Brethren in 1732.

London Association in aid of Moravian Missions in 1817.

Other missionary societies are framed for the purpose of operating within the United Kingdom, one object of which is attended to by the Society for promoting Christianity amongst the Jews, founded in 1808, whose expenditure has been very liberal, and another called the Philo-Judæan, established in 1826.

Besides these, there are societies for promoting missions at home, and in the neighbouring European countries. They are the Continental Society, the Christian Union Society, the Irish Evangelical Society, the Hibernian Society, the Baptist Irish Society, the London Itinerant Society, the Village Itinerary Society, British and Foreign Seamen's Society, Port of London Society for promoting Religion among Seamen, Port of London and Bethel Union Society, and Episcopal Floating Church Society.

According to the best accounts which can be obtained, the whole sum annually collected in London for this class of benevolent designs amounts to nearly L.350,000. Much of the money is raised, and many subscriptions procured, by public meetings, at which exciting speeches are made, describing the success of their operations, and pressing on the auditors the necessity or piety of assisting these institutions. Meetings of this description have become so numerous, that a large public building has been erected for holding them, called Exeter Hall, in the Strand. It is a fine structure, and the interior is very appropriate for the intended purpose.

London is the source from which the law of England is dispensed over the whole kingdom, and in it originate all the important legal proceedings. On this subject, the Inns of Court, in which legal knowledge is imbibed, and in which the initiation of the most respectable branch of practitioners is performed, deserve the first notice. There are four of these inns, which have the power to call to the bar such students of their society as have passed the due preparatory period, which occupies five years for all who have not graduated at the universities, and three years for those who have proceeded to the degree of Master of Arts. No examination takes place at their admission. These societies are of a nondescript nature, not being corporations in the legal sense, but yet possessing considerable wealth, and exercising great power, with little or no actual controul, by means of a body called the Benchers, which is chosen by rules of their own.

The *Temple* is situated partly within and partly without the city. It receives its name from the religious military order of the Knights Templars. They were originally crusaders, who, happening to be quartered in places adjacent to the holy temple of Jerusalem, in 1118, consecrated themselves to the service of religion by deeds of arms. Hugo de Paganis and Geoffrey of St Omers established the order, by binding themselves to chastity and obedience, and professing to protect the pilgrims to the Holy Land from all wrong and robbery on the road. By their devotion, and the fame of their gallant actions, they became very popular in every part of Europe, and were so enriched by the favour of princes and other great men, that, at the time of their dissolution, they were found to be possessed of sixteen thousand rich manors. Their riches seem to have been their chief crime, though their wealth enabled them to indulge in excessive luxury. Crimes were imputed to them, and they were condemned without proof. They founded the Temple in London in the year 1185, and continued in possession of it till their suppression in 1310. When they were condemned to penance and dispersion, Edward II. granted their house to Thomas Earl of Lancaster, and on his rebellion to Aymer de Valance, Earl of Pembroke, on whose death it reverted to the crown. It was then given to the Knights of St John of Jerusalem, for their gallant defence of the Island of Rhodes against the Turks. These knights, in the reign of Edward III., granted the Temple to the students of the common law, to whose use it has ever since been applied.

The church of the Temple is an object of great curiosity. It was erected in 1185, on the model of the church of the holy sepulchre at Jerusalem. The entrance is through a door with a Saxon arch. The form is circular; it is supported by six round arches, each resting on four round pillars, bound together by a fascia. It has undergone a thorough reparation since 1828, and has been recased with stone. It contains many monuments of eminent men connected with the establishment during its existence; amongst others, of the eminent lawyers Plowden, Selden, and Vaughan. A division of the establishment was made into the Inner and Middle Temple, which now form two distinct bodies, having their members, revenues, and regulations separate, but enjoying the church in common. Each of these bodies admits or calls students to the bar; each provides for them tables of three grades for the benchers; the barristers and the students are provided, during term time, at very moderate rates. The whole of the buildings are divided into separate suites of apartments, in which men of all degrees of expenditure find accommodation. The garden of the Temple, formed by embankment on the side of the river, is a pleasant promenade, which has been rendered celebrated by Shakspeare, who makes it the place where the badge of the white and red rose originated, under which the respective partizans of the houses of York and Lancaster were arranged. The chaplainship of the Temple is a valuable and honourable office, and has been filled by some of the greatest divines of the English church. The chaplain is denominated the Master.

Lincoln's Inn is an old building in Chancery Lane, partly in the liberty of the Rolls, and partly in Westminster. It was originally a Dominican monastery, but, on the monks removing to Blackfriars, the ground was granted to Henry Lacy, Earl of Lincoln, who built upon it an inn, or residence for himself, where he died in the year 1312. From this the present name has been derived. In the reign of Henry VIII., one of the Bishops of Chester granted leases of the buildings to certain students of the law, reserving a lodging for themselves when they came to London. It has a chapel built on massive pillars, with a dry walk under it. The hall is used as a court out of term. The power of calling to the bar, the service of the tables, and other matters, are nearly regulated in the same manner as in the two Temples. The new square and stone buildings contain many good apartments; and there have been other modern erections.

Gray's Inn, the last of the four establishments from which barristers emanate, is in Holborn. It was the residence of the Lord Greys in 1315, and was sold by one of them to Hugh Denys, and then came to the Prior of Sheene, who disposed of it to the students of law. It has its hall adorned with a curiously carved oak-screen, with portraits of the three kings of the house of Stuart. The chapel is not remarkable; but it has a good and spacious garden, in which new buildings have recently been erected. The regulations for admitting barristers, for the service of the table, and for other matters, differ but little from those of the Temple and Lincoln's Inn; but the number of professional men, especially of barristers, is much larger in proportion to the establishment, than in the other Inns of Court.

There are other piles of building in the same vicinity, still called inns, which were such probably in former times, and occupied as preparatory schools of law, or by the attorneys and attendants on the courts. These are, Clement's Inn, with a hall, in which there is a portrait of Judge Hale, and those of some others, and, in the square, a fine statue of a negro, holding in his hand a sun-dial. Thaves's Inn, in Holborn, has been purchased by the society of Lincoln's Inn, and is occupied by private persons. Clifford's Inn, in Fleet Street, is small and old. Staples Inn, in Holborn, is said to have been formerly the wool-market; in its hall are casts of the twelve Roman Emperors, and some portraits. Lyon's Inn, in Newcastle Street, was originally an inn with that sign; it is small. Furnival's Inn, in Holborn, belonged to a noble family of that name, now extinct; it has been lately rebuilt, in a style which makes it an ornament to the street. Barnard's Inn is also in Holborn, but has nothing to render it remarkable. Symond's Inn, in Chancery Lane, was formerly used by the Masters in Chancery, before their removal to the public office in Southampton Buildings. New Inn, in Wych Street, is small, and in some way connected with the Middle Temple. There are in all of these separate apartments, reached by common staircases, into which they open. They are let indiscriminately to any tenants, but are chiefly occupied by persons of the different branches of the legal profession. There are two others, called Sergeant's Inn, one in Chancery Lane, mostly occupied by sergeants-at-law; the other in Fleet Street, with private dwellings, except that the Amicable Insurance Company have their office in it.

Courts of Law.

The Courts of Law established in the metropolis are, in number and jurisdiction, conformable to the requisitions that are made on them by the nature and division of the law, and by the business transacted in them. The chief courts are in Westminster Hall. On entering the great or eastern door, the first on the right hand is the King's Bench; the Common-Pleas Court, the Exchequer, the Bail Court, the Vice-Chancellor's and the Chancellor's follow in succession; and above stairs is the Court of the Master of the Rolls. In a building, once a part of the Exchequer, adjoining, and which, according to tradition, was the Star Chamber, is a court for the new Judges of Bankruptcy.

During term time these courts are occupied by the respective judges. They are neatly and appropriately fitted up, and tolerably commodious. In the intervals between the terms, the Lord Chancellor, the Vice Chancellor, and the Master of the Rolls, sit at Lincoln's Inn; the Chief Baron of the Exchequer in Gray's Inn; and the Chief Justice of the King's Bench and of the Common Pleas try jury causes at the Guildhall of the city, where appropriate courts are prepared to receive them.

There are two civil-law courts in Doctors Commons. The first is the ecclesiastical court, which takes cognizance of blasphemy, heresy, divorces, adultery, fornication, simony, incest, and some other crimes; and also regulates the induction to church preferments, the rights of pews, churches, and burial-grounds, the probates of wills, and the granting administration in cases of intestacy. It is the depositary of all wills in the province of Canterbury; and they are so carefully preserved and registered, that reference can be made to any will in a few minutes, and the examiner, for the small fee of a shilling, may read any one in the place. The other court, called the Court of Admiralty, is empowered to decide on all cases of capture of ships, to judge of crimes committed on the high seas, and to determine disputes between sailors and their captains in merchant ships. The Court of Arches is also held at the same place, and is a court of appeal from the ecclesiastical court. There are two classes of practitioners in these courts, the proctors and the advocates. The former must be admitted by a fiat from the archbishop, before the judges will admit them to practise. The advocates are only such as have taken the degree of doctor of laws in one of the universities. The whole building is somewhat in the style of a college, inclosed with gates, and contains, besides the courts, apartments for the judges and officers, and chambers for the advocates.

There are some other inferior courts, such as that of the Lord Mayor, of the Sheriffs, several for the recovery of very small debts, called Courts of Request, and the Marshalsea, or Palace Court. To these may be added the Insolvent Debtors' Court, which has much more practice than any of them, being presided over by regular and well-instructed Judges, whose jurisdiction extends over the whole kingdom. Upon fairly giving up the whole of his effects, and rendering a true account of his debts, the prisoner is by this court released from confinement.

The principal criminal court is that of the Sessions-house in the Old Bailey, the jurisdiction of which was extended, by a law in 1834, to many parts of Surrey, Kent, and Essex, where it did not reach before. It is nominally presided over by the Lord Mayor and aldermen; but the prisoners are tried by the regular judges, a few by the Recorder, and some by the Common Sergeant. Inferior offences are tried before the justices of the peace for the county of Middlesex, at the Sessions-house at Clerkenwell. Misdemeanors are also tried at Horsemonger Lane, by the justices of Surrey, and at Guildhall by the city authorities. The Lord Mayor sits at the Mansion-house, and an alderman at Guildhall, to judge in smaller matters, and to inflict punishment correspondent to their guilt on offenders. There are eight offices of stipendiary magistrates beyond the limits of the city, who, like the Lord Mayor and aldermen, have the power to punish, by fine and imprisonment, for disorderly conduct, and for various other offences specified in various acts of parliament. These magistrates, like those of the city, examine into crimes of the highest nature, and, on the charge being made probable, commit them to prison, to be tried at the gaol delivery. At each of these offices three magistrates attend, and they have from eight to twelve constables attached to them, called police-officers, who, besides their pay, make profits from the services of summonses, warrants, searching for offenders, and portions of penalties.

Prisons.

The prisons in London are appropriated to various purposes, and under different authorities. The first to be noticed is *Newgate*, which is under the jurisdiction of the Lord Mayor, aldermen, and sheriffs, and is the common gaol for London and Middlesex. It was burned by the mob in the riots of 1780, but speedily rebuilt, as at that time there was little wood in it. It is divided for three classes of culprits; one part for convicts, another for those to be tried and such as have been committed for misdemeanors, and the third divided into two parts, for tried and untried females. The number of prisoners varies from 350 up to 900. There is a chapel within the walls, in which divine service is performed twice every Sunday, and once on three other days of every week. The largest of the prisons is the Middlesex house of correction in Coldbath Fields, which commonly contains about 1200 persons, who are employed in picking oakum. A tread-mill is in operation; and of late silence amongst the prisoners has been enforced, which seems to have produced a very beneficial effect.

Giltspur Street Prison is near to Newgate. It is a pile of considerable extent, of rustic stone work, but has only apartments for about 200 prisoners. These are such as are under examination previous to commitment, besides vagrants or disorderly persons taken up at night. It is sometimes used as a house of correction, and the persons sent to it are employed in various kinds of work.

Clerkenwell Prison is near the house of correction in Spa Fields, and is a common gaol for the county of Middlesex. It receives prisoners of all descriptions, and is capable of containing about 300 persons.

Fleet Prison, in Farringdon Street, is chiefly used for the confinement of debtors, or for such as are committed by the Court of Chancery or of the Common Pleas for contempt. The average number of persons confined in it is about 250; but there are about 60 others within the rules or limits, which extend both up Ludgate Hill and Fleet Street.

The *King's Bench Prison*, in Southwark, is large, and, by the improvement of the law, has of late been but thinly occupied. It is principally a place of confinement for debtors, or of such as are sentenced to it for libels or other misdemeanors. It contains 220 rooms, and is surrounded with a lofty brick wall. Debtors are allowed to purchase what is called the liberties, that is, to have lodgings without the walls, but within the rules, which extend over the whole of St George's Fields, and into parts of Southwark.

Horsemonger Lane Prison, in Southwark, is the gaol for the county of Surrey. It is a large building, erected in 1781, and surrounded with a lofty wall, and it is occupied both by felons and debtors. On the top of it is the place of execution for criminals sentenced to death. The number confined varies from 200 to 300.

The *Borough Compter*, though under the jurisdiction of the Corporation of London, is restricted to some of the parishes in Southwark. The experiment is here tried of separating and classifying the prisoners, who are employed in various kinds of labour.

New Bridewell Prison is in St George's Fields, and a substitute for the City Bridewell. It is devoted to the correction and education of the idle and disorderly, who are chiefly employed on a tread-mill, by which the corn is ground for the support of the patients in Bethlehem Hospital.

The *New Debtor's Prison* in White Cross Street, is used only for such debtors as were formerly confined in Newgate amongst felons. It is capable of containing 400 persons.

The *Penitentiary* at Millbank has been a most expensive experiment on the Panopticon principle. It is intended to reform the convicts, who are kept regularly at work in various manufactures; and attention is paid to their moral and religious instruction. The females are under the management of officers of their own sex. The prisoners receive a part of their earnings, and the remainder is given to them on their being discharged. It is capable of receiving 400 male, and the same number of female prisoners.

A Statement of the Number of Persons charged with Criminal Offences who were committed to the several Gaols in London and Middlesex for Trial during the 21 *years from* 1813 *to* 1833, *both inclusive.*
